eight hundred printed folio pages, and the four volumes of Blue Books which embody the reports are undoubtedly the most valuable of existing storehouses of information on the Museum. It is to be regretted, however, that much of the evidence relates to personal matters only, and that several points of the management of the Museum on which light would be welcome to the public were left in darkness. The committee of 1835 recommended several alterations in the management of the Museum, some of which were adopted by the trustees, who, in 1837, laid before the House of Commons a series of extracts from their minutes, to show how far they had complied with these suggestions. The committee also strongly recommended increased liberality to the institution on the part of the House of Commons; a recommendation which appears to have borne its fruits, for from that time to the present the spirit of the House of Commons has been evidently in favour of the Museum, and has rather encouraged than repressed proposals for the extension of the national collection on the part of the trustees and the Treasury. The Royal Commission was nominated to inquire into the whole management of the Museum, but brought its labours to an unexpected close after an inquiry almost confined to the Printed Book department, and chiefly directed to the questions connected with the Catalogue. The commissioners stated their wish that no change should take place in the Board of Trustees, but that an Executive Council, to be composed of a chairman, four members elected by the trustees, and two named by the crown, the chairman and the two royal members receiving a salary, should be entrusted with the whole patronage and management of the Museum. No measure founded on this report has, however, been submitted to the legislature. In the present year, 1859, a proposal for a committee of the House of Commons on the Museum was brought forward by Mr. Gregory, the member for Galway, and acceded to by the Earl of Derby's government, but had not yet passed through the necessary forms when parliament was dissolved. It was chiefly intended to inquire into the expediency of removing the natural history collections from the Museum.

The Principal Librarian is the name assigned to the chief officer of the Museum, in the Act of Parliament which founded it, and the name is still continued, although his duties have no connexion with the library more than the other departments, all of which, without exception, are under his superintendence. The principal Trustees nominate two persons for this appointment, one of whom is selected at pleasure by the sovereign. The first principal librarian was appointed in 1756, and the sixth in 1856, exactly a century after, giving twenty years as the average term of tenure. It is remarkable that, from the first establishment, the office has been alternately held by an Englishman and a foreigner. The list is as follows:—

1. Gowin Knight, M.D., 1756-1772;
2. Matthew Maty, M.D., a Dutchman, 1772-1776;
3. Charles Morton, M.D., 1776-1799;
4. Joseph Planta, a Swiss, 1799-1827;
5. Sir Henry Ellis, K.H., 1827-1856;
6. Antonio Panizzi, an Italian, 1856 (the present principal librarian).

Little is known of Dr. Gowin Knight, the first chief officer, whose claims to the appointment prevailed over those of Sir John Hill, the botanist, an eager candidate for the post. Some notices of him are to be found in Nichols's 'Literary Anecdotes.' His successor, Dr. Maty, had come to England, in 1740, at the age of twenty-two, but published, in Holland, for some time after, a periodical in the French language, containing an account of English literature, the 'Journal Britannique;' and Gibbon, who was a contributor, says, that the "humble though useful labour" of a reviewer "was not disgraced by the taste, the knowledge, and the judgment of Maty." He was appointed one of the under-librarians of the Museum at its first institution in 1753, and when, after nearly twenty years' service, he succeeded to the principal librarianship, much was expected of him, but the hope was frustrated by his early death in 1776. His successor, Dr. Morton, who like both his predecessors had practised as a physician, had also been an under-librarian of the Museum from before its opening in 1756, and he held the appointment till his death in 1799, at the age of eighty-three. He was author of a paper in the 'Philosophical Transactions' on the supposed resemblance between the Egyptian hieroglyphics and the Chinese character. Lives both of Dr. Maty and Dr. Morton are to be found in Chalmers's and the usual biographical dictionaries. The fourth principal librarian, Joseph Planta, was born in the country of the Grisons, in 1744, and came to England, in 1752, with his father, the Rev. Andrew Planta, who was minister of the Reformed Church in London, and tutor in Italian to Queen Charlotte, and who, in 1758, became an assistant-librarian at the Museum. The son was intended for a diplomatic career, but on the death of his father, in 1773, succeeded to his post at the Museum, and continued there from 1773 to 1827, holding, also like both his predecessors, a post in the Royal Society. He published a 'History of the Helvetic Confederation,' abridged from Johann von Müller, and a dissertation, in the 'Philosophical Transactions,' on the Romansh language, spoken by the Grisons. The largest biography of him we have seen was written by Falkenstein, the librarian of Dresden, and published in the German periodical, the 'Zeitgenossen.' He was succeeded by Mr., afterwards Sir Henry, Ellis, the circumstances of whose appointment are curiously illustrated by some passages in the pub-

lished life of Fynes Clinton, whose name was sent up to the king with that of Sir Henry, by the then principal trustees, in accordance with the rule, that two names are to be submitted to the sovereign for the vacant post of principal librarian. Sir Henry is the author and editor of numerous volumes, from the 'History of Shoreditch,' in 1798, to the 'Pilgrimage of Sir Richard Guilford,' in 1851, and, among others, of some volumes on the Townley marbles, and also on the Elgin and Phigaleian marbles in the Museum, published in the 'Library of Entertaining Knowledge.' When he retired from the chief librarianship in 1856, he had been fifty-one years an officer of the establishment, having, in 1805, succeeded the Rev. Samuel Ayscough as assistant-librarian. His acquaintance with the Museum had commenced even previously, Sir Henry having been in 1795, as he still is in 1859, a frequenter of the reading-rooms. The united experience of the third and fifth principal librarians is thus seen to extend over the whole history of the Museum, from its commencement to the present time, a period of more than a century.

Mr. Panizzi is well known as the editor of Boiardo and Ariosto, to whose two poems united he prefixed an admirable essay on the narrative and romantic poetry of the Italians. Even in the present year, 1859, he has added to his labours on Italian literature by the publication of a collation of the four first editions of Dante, with a bibliographical preface. He entered the Museum in 1831 as extra assistant-keeper of the printed books, and in 1837 was appointed keeper of the department, a post which he filled for nineteen years with remarkable efficiency. Previously to his engagement at the Museum, he was professor of the Italian language and literature at the present University College, then called the London University.

The next most important office to that of the principal librarian is that of secretary to the trustees, which was held separately by the Rev. Josiah Forshall from 1837 to 1849, when he resigned, and the office has since been held by the principal librarian.

The Museum is at present divided into eight departments, under separate officers:—the Departments of Printed Books, of Manuscripts, of Antiquities, of Prints and Drawings, of Zoology, Geology or Palæontology, Mineralogy, and Botany. To each of these departments, there is a chief officer called a Keeper; to those of Natural History there is also a newly-appointed superior officer, who bears the name of superintendent. The departments are of very different extent and importance: the keeper of the Printed Books has under him two assistant-keepers, twenty-five so-called "assistants," who are gentlemen of education and acquirements, chiefly employed in making the catalogue, thirteen transcribers, and more than forty attendants; while the keeper of the prints and drawings has but one transcriber and two attendants, and the keeper of the mineralogy one attendant only. In the earlier stages of the Museum history the officers were often removed from one department to another, a practice which renders it desirable to say what is to be said on the biography of the most prominent officers in connection with the general history of the institution, rather than with that of the separate departments. One of the earliest officers, as keeper of the natural history department, was James Empson, who had been in Sir Hans Sloane's lifetime, keeper of his museum. The name of Dr. Solander, a Swede, who had accompanied Sir Joseph Banks in his voyage round the world, and who was assistant librarian and then keeper, between 1765 and 1782, the date of his decease, is preserved in perpetual remembrance by his invention or contrivance of "Solander cases," a kind of easily manageable box in the shape of a volume which is useful for the preservation of unbound pamphlets. The Rev. Charles Godfrey Woide, a Prussian, an assistant librarian (1782-91), edited with much care the New Testament, from the Alexandrian Codex, hereafter to be mentioned, a peculiarly valuable manuscript of the Scriptures preserved in the Museum. The Rev. Henry Hervey Baber, who entered as assistant librarian in 1807, and became keeper of the printed books in 1812, completed the undertaking by editing the Old Testament portion of the Alexandrian Codex; and was finally rewarded for doing so by the presentation of a valuable living in the country, to which he retired in 1837, resigning his post at the Museum. The Rev. Samuel Ayscough had been for some time in the employment of the Museum, when in 1787 he was appointed to an assistant librarianship, which he retained till his decease in 1805. Mr. Ayscough seems to have had a peculiar pleasure in making indexes and catalogues. He compiled the consolidated indexes for the sets of the 'Monthly Review,' the 'British Critic,' and the 'Gentleman's Magazine,' and the index to the remarkable passages and words in Shakspeare, which was the completest concordance to Shakspeare, till that of Mrs. Cowden Clarke. He made, in 1782, the catalogue of the manuscripts at the Museum, belonging to the Sloane and Birch collections, a book far from correct, but still of use till supplanted by a better. He also assisted in the compilation of the catalogue of the printed books of the Museum, published in 1787, in two volumes folio, of which the other portions were taken by the Rev. S. Harper—assistant librarian from 1756, and keeper from 1765 to 1803—and the Rev. Paul Henry Maty, a son of Dr. Maty, who like Planta, entered the Museum on the death of his father, and only survived till 1787, the year of the publication of the catalogue. Andrew Gifford, D.D., assistant keeper of the manuscripts from 1756 to 1784, was remarkable for having at his decease, bequeathed to the Baptist Library at Bristol, several rare printed books, including a copy of an edition of Tyndale's Testament,

absolutely unique, and which could not have found a more appropriate resting-place than the British Museum. Dr. Edward Whitaker Gray, M.D., assistant and afterwards keeper of the natural history (1778—1807), was a relative of Dr. John Edward Gray, the present keeper of the zoology; Dr. Gray's successor in the keepership was Dr. George Shaw, a well-known writer, whose 'Naturalist's Miscellany,' and 'General Zoology,' are still referred to. In 1803 to 1806 the Rev. William Beloe, author of the 'Sexagenarian,' was keeper of the printed books, and one fruit of his connection with the Museum was his six volumes of 'Anecdotes,' in which he gives somewhat dry particulars of many books in the library, especially of those in the Cracherode collection. While the Rev. Samuel Ayscough was index-maker to the 'British Critic,' the Rev. Robert Nares was editor, and figured not only as a writer but a novelist, in 'Thinks I to Myself, Thinks I.' He was assistant in 1795, and rose to be keeper of the manuscripts in 1799, on the promotion of Planta, but resigned the office in 1807, on being appointed to an archdeaconry. His successor in the manuscript department was Francis Douce, the antiquary, who only held it till 1812, when, taking offence at some circumstances of his position, and being in possession of a good private fortune, he resigned, and at his decease, in 1834, left his valuable library to increase the stores of the Bodleian. The Rev. Thomas Maurice, "the author of 'Indian Antiquities,'" as he delighted to style himself, entered the Museum as assistant librarian in 1799, at the promotion of Nares, and remained unpromoted till his decease in 1824. Among his numerous works he had commenced an autobiography, which contains some agreeable gossip, but does not come down to the time of his connection with the Museum. Mr. Taylor Combe, who entered in 1803 as assistant librarian, became in 1807 keeper of the new department of antiquities, which was founded, as already mentioned, in consequence of large additions, and installed in a new building. He held the office till 1826, when, by his unexpected demise, Mr. Edward Hawkins, who had only entered the Museum that year, at once mounted to the keepership. Mr. William Alexander was, from 1808 to 1816, keeper of the prints, which then formed a portion of the department of antiquities. He had accompanied Lord Macartney in his embassy to China, and his published views in China testify to his skill as a draughtsman. His successor, Mr. John Thomas Smith, from 1816 to 1833, was the author of the amusing volumes entitled 'Nollekens and his Times,' and many other works of less note. The next keeper of the prints was Mr. William Young Ottley, whose works on early engravings are still the first referred to in any question on the history of the art.

Mr. Charles König, an accomplished German, who entered as assistant in 1807, and was promoted in 1813, continued keeper of the mineralogy till his death in 1851. He had been one of the Banksian librarians, and continued united in friendship with Mr. Robert Brown, who came to the Museum in 1827 as head of the Banksian or botanical department. Mr. Brown was recognised by foreigners as well as Englishmen as the first botanist in Europe. Humboldt styled him "Botanicorum facile Princeps," and his works are perhaps better known in Germany than in England. Mr. John George Children, who was assistant librarian in 1816, and in 1837 became keeper of zoology, was the friend of Sir Humphry Davy. He resigned his post in 1840, on the death of his wife. A volume of his biography has been privately printed by his family since his decease in 1852. Dr. Leach, who entered the Museum in 1813 and retired in 1822 on account of ill health, which continued till his decease in 1826, was a naturalist of great eminence, unsurpassed in zeal for science and acuteness of intellect, but remarkable also for eccentricity of character. His labours at the Museum were of great importance in improving its classification. His successor, Dr. George Henry Noehden, a German, assistant librarian from 1822 to 1826, was the author of a much esteemed German grammar, and corresponded with Goethe. The Rev. Henry Francis Cary, assistant librarian of the Printed Books from 1826 to 1837, is universally known as the translator of Dante. His biography was published by his son in two volumes, and contains some matter of interest with regard to the Museum, especially on the circumstances which led to the resignation of Mr. Cary,—circumstances which are fully and satisfactorily explained in Mr. Panizzi's evidence before the Royal Commission in 1848. The life of Mr. Cary's successor, the Rev. Richard Garnett, assistant librarian from 1838 to 1850, has also been written by his son, but in a briefer form, and is prefixed to a collection of the *Philological Essays* of Mr. Garnett, chiefly consisting of papers from the *Transactions* of the *Philological Society*, and articles inserted in the *Edinburgh* and *Quarterly Reviews*. Dr. Frederick Henry Trithen, by birth a Swiss, but removed when a child to Russia, and generally considered as a Russian, was an assistant in the Printed Book department in 1844, and resigned in 1845. In 1848 he was elected the first professor of modern languages at the University of Oxford on the Taylor foundation. Mr. Edward Edwards was an assistant in the same department from 1839 to 1850. He is the author, among other works, of the article on *Libraries* in the eighth edition of the *Encyclopædia Britannica*, and of *Memoirs of Libraries*, including a *Handbook of Library Economy*, published in two volumes in 1859, in which is contained the longest and most elaborate history of the Museum library that has yet appeared extending to 120 octavo pages. The reader of this history would however hardly suppose that the writer was more

intimately acquainted with the Museum library than with the Bodleian, his account of both wearing the appearance of being entirely derived from books. M. Louis Augustin Prevost was also assistant in the same department from 1843 to his death in 1858, employed in cataloguing the Chinese collection. His fondness for languages was remarkable, and he had studied more or less minutely upwards of forty, with several of which he was well acquainted. Mr. Thomas Oliphant, secretary of the Madrigal Society, and author of the 'Musa Madrigalesca,' catalogued the music both in the Printed Book and the manuscript departments from 1841 to 1850. In the latter year he resigned, and may now be considered the poet of the Court for which he writes verses on festal occasions. Dr. Rosen, an eminent Sanscrit, Arabic, and Syriac scholar, editor of the 'Radices Sanscritæ,' and many other works of importance, was an assistant in the Manuscript department for some years previous to his death in 1837, and was at the same time professor of oriental languages at the London University. The Rev. William Cureton passed in 1837 from the assistant librarianship of the Bodleian to the assistant librarianship of the Manuscript department at the Museum. Mr. Cureton had given his chief attention to Arabic, and published various works in that language. The acquisition of the Syrian manuscripts during his librarianship gave him an opportunity such as might not have occurred for ages of turning to the advantage of learning his knowledge of Syriac. He resigned in 1850 on receiving preferment in the Church, and in 1859, as has been already mentioned, was appointed by the Queen the Queen's trustee at the Museum. Mr. John Holmes, his successor in the assistant librarianship (1850-54), had been an assistant from 1830, and had given evidence on catalogues before the Committee of the House of Commons in 1836. He was more inclined to contribute to the works of others than to publish anything of his own, and paid the inevitable penalty of the non-acquirement of reputation, which was within his reach. One of his contributions to the 'Quarterly Review' was an article on catalogues of libraries. The Rev. Henry Octavius Coxe, formerly assistant in the Manuscript department (1833), and now assistant librarian at the Bodleian, has been able since his removal to Oxford to publish several valuable catalogues of manuscripts in that university. There were at the same time in the Museum two officers of the name of Doubleday,—one of whom, Mr. John, was an American, and the other, Mr. Edward Doubleday, had travelled extensively in America,—but who were no relations. Mr. Edward Doubleday, an assistant in the natural history department (1842-49) was author of a magnificent work on the 'Genera of Diurnal Lepidoptera.' Mr. John Doubleday, long an assistant in the antiquities department, had an opportunity of signalising the ingenuity for which he was noted by the completely successful restoration of the Portland vase, when it was shivered to atoms in 1845. Mr. Charles Newton, an assistant in the antiquities from 1840 to 1852, afterwards consul at Mytilene, and now (1859) consul at Rome, formed the design of prosecuting his researches in antiquity on the spot in Greece and Asia Minor, and with that view applied to government for a consulship in the Levant, which was given to him by Lord Granville. His excavation of the mausoleum at Halicarnassus, and others which he has made and is making, are materially augmenting the treasures of the institution to which he belonged. Mr. Thomas Burgon, also an assistant of the antiquities department (1844-58), entered the Museum late in life, and had already passed many years in commercial pursuits in Asia Minor, where he acquired that knowledge of Greek coins which was his distinguishing characteristic.

Such are some of the past officers of the Museum, taking the word "officers" in its ordinary sense, not in the technical one in use in the official documents of the Museum, in which it is assigned to no one beneath the rank of an assistant-keeper. Of the present officers, only those will be mentioned whose names are affixed to some separate printed publication.

The keeper of the Printed Book department, Mr. John Winter Jones, has had the good fortune to discover among the treasures now under his charge, two volumes unknown to any previous bibliographer, which in the 'Archæologia' for 1846, he has demonstrated to be in the type of Caxton. Mr. Thomas Watts, the assistant-keeper, has shown, on the other hand, that a newspaper in the Museum which was supposed to be the first of all newspapers, 'The English Mercurie,' of 1588, is an entire fabrication. Both Mr. Jones and Mr. Watts have written on numerous other occasions, and in these papers they have produced information which all succeeding writers on the subject are bound to notice. The Rev. Thomas Hartwell Horne, who has been connected with the Museum library in some degree from the period when he framed the classed index to the catalogue of the Harleian manuscripts in 1808, and who in 1824 was appointed to carry out the plan of a classed catalogue, which was subsequently arrested, is universally known in America as well as Europe for his 'Introduction to the Bible,' which has been a text-book for students since its first publication in 1818. In the opinion, however, of many, even this work is surpassed in neatness of execution by his 'Introduction to Bibliography,' which has not met with the distinguished success it deserved. A complete list of Mr. Horne's numerous publications is to be found in Allibone's 'Dictionary of English and American Authors.' Mr. William Brenchley Rye has edited a volume for the Hakluyt Society on early travels in Florida; and to Mr. George Bullen we are

indebted for an elaborate 'Catalogue of the Books in possession of the British and Foreign Bible Society,' executed on a plan similar to that of the Museum catalogue. As secretary of the Hakluyt Society, Mr. Richard Henry Major, who catalogues and arranges all the maps of the Museum, had for many years the chief task of managing the affairs of that society, and was himself the editor and translator of many volumes, in particular of Columbus's Letters, and Herberstein's Russia. Mr. Joseph Zedner, to whom the cataloguing of the Hebrew books is entrusted, has in his "Auswahl historischer Stücke," a collection of extracts from Hebrew historians of all ages from the Talmud to Mendelssohn, not only shown his intimate acquaintance with Hebrew literature, but shown also that this is but a part of his acquirements. The poem of 'The Angel in the House,' has placed Mr. Coventry Patmore in a high rank among our living poets, and is still more warmly appreciated in America than in England. Mr. Richard Garnett has given earnest of high talents in a volume of poems, and has edited the 'Philological Essays' of his father. The Rev. Joseph Benjamin Maccaul and Mr. Collyer Knight have issued some publications of a theological cast.

Sir Frederick Madden, keeper of the manuscript department, is one of the best known antiquarian authors of England, editor, in conjunction with his predecessor in office, the Rev. Josiah Forshall, of the edition of Wickliffe's Bible, to prepare which fifty-five copies were collated; and editor also of the romances of 'Sir Gawayne,' and 'Havelok the Dane,' of 'Layamon's Brut,' &c. The assistant-librarian, Mr. Edward Augustus Bond, is author of some articles in the 'Archæologia,' and is now editing for the government the Trial of Warren Hastings. Mr. Charles Rieu has published some Latin dissertations on Arabic Poets, has edited Sanscrit works, and is professor of Oriental languages at University College. Mr. Edward Leaven and Mr. Stephen Armytage Hamilton have published works on history. Mr. Richard Sims is author of a 'Handbook to the Library of the British Museum,' more complete for the manuscript department than for that of printed books, of an 'Index to the Pedigrees and Arms contained in the Heralds' Visitations at the British Museum,' and of a 'Manual for Genealogists,' containing useful indications of where to search for any particular fact of a genealogical nature required.

Mr. Edward Hawkins, keeper of the antiquities, has published a work on the Silver Coins of England. The assistant-keeper, Mr. Samuel Birch, is an eminent Egyptian scholar, author of several works on Egyptian Antiquities, and of an elaborate 'History of Ancient Pottery' in two octavo volumes. To Mr. William Sandys Wright Vaux we are indebted for a 'Handbook to the Antiquities of the British Museum,' and for an account of 'Nineveh and Persepolis,' which has run through four editions, and been translated into German. Mr. Augustus Woolaston Franks, who holds the office of director of the Antiquarian Society, is a contributor to the great work on the Manchester Exhibition, 'The Art Treasures of the United Kingdom,' and Mr. Reginald Stuart Poole is the author of 'Horæ Ægyptiacæ,' and of the article *Egypt* in the eighth edition of the 'Encyclopædia Britannica.'

Mr. William Hookham Carpenter, keeper of the prints and drawings, is author of a volume of 'Pictorial Notices,' chiefly consisting of a life of Sir Anthony Vandyck.

In the departments of Natural History, the name of the superintendent, Professor Richard Owen, is more universally known and respected than any other name in his branch of science, since that of Cuvier. Dr. John Edward Gray, the keeper of zoology, has made numerous contributions to zoological science, of which no less than 425 are enumerated in Agassiz and Strickland's 'Bibliography of Zoology,' published in 1852, which takes notice of papers in periodicals as well as separate publications. Dr. Gray is president of the Botanical Society. His brother, Mr. George Robert Gray, is the author of several works on ornithology, and, in particular, the standard work, the 'Genera of Birds,' in three folio volumes. Mr. Adam White has written popular histories of mammalia, birds, British Crustacea, &c., in addition to numerous scientific papers. Dr. William Baird is author of a 'History of British Entomostraca,' and a 'Cyclopædia of the Natural Sciences.' Mr. George Robert Waterhouse, keeper of the geological department, has issued the first two volumes of a 'Natural History of Mammalia.' Mr. Samuel P. Woodward is author of an excellent 'Handbook of Mollusca.' Finally, Mr. John Joseph Bennett, keeper of the Botanical department, is associated with Dr. Horsfield in the publication of the 'Plantæ Javanicæ rariores.'

Some of the most important labours, however, of the officers of the Museum are comprised in the catalogues and descriptions of the collections entrusted to their charge, which have from time to time been issued by the Institution, and which are of various dimensions and cost, from a penny pamphlet to a folio of four guineas and a half. An account of these will be given at the close of our view of the Museum, when we have gone over the separate departments, which, for the sake of convenience, may be arranged in the following order: the Printed Books, the Manuscripts, the Antiquities, the Prints and Drawings, the Departments of Natural History.

The Printed Book Department.—At the time that the Museum was first opened, in 1759, the library of printed books had already received a donation which emphatically marked it as the national library of England. In 1757 King George II., by an instrument under the

great seal, presented to it the royal library, which had been accumulated by the sovereigns of England, from the time of Henry VII. downwards. The collection was indeed not large, being estimated at about 10,500 volumes; but it was rich in interest, from its numerous memorials of the Tudors and the Stuarts. The volumes brought together by Henry VII. himself comprised a remarkable series of illuminated books on vellum, from the press of the French printer, Anthony Verard. One of them, a French Boethius, is remarkable for bearing a dedication addressed to the king of England, while in another copy in the library the dedication is to the king of France, and on examination it is found that, in the king of England's copy, the word "Engleterre" has been inserted with a pen. In the reign of Henry VIII. more genuine presentation copies abounded; of one book, a translation of Galen, 'De Ratione Medendi,' there are two copies, both presented by the author, Dr. Linacre, the first president of the College of Physicians, one to Cardinal Wolsey, and the other to the king. A splendid vellum copy of the Bible of 1540 is interesting as containing in the title-page, said to be from a design by Holbein, a figure of Henry giving the Bible to his subjects, on which his own eyes must probably often have rested. It now stands in the Museum in the same press with a New Testament that belonged to Anne Boleyn. There is also King Henry's copy of his 'Assertion of the Sacraments,' the book which procured him the title of Defender of the Faith. Interesting memorials of the three sovereigns who were children of Henry, are to be found in the Greek grammar of Edward VI., in Queen Mary's copy of Bandello's novels, the book which supplied so many plots to Shakspeare, and in the volume of the 'Lives of the Archbishops of Canterbury,' the first book privately printed in England, presented to Queen Elizabeth by its author, Archbishop Parker. Another volume, which must once have belonged to the royal collection, but came to the Museum through the bequest of Mr. Cracherode, is Queen Elizabeth's copy of the first book printed in Anglo-Saxon, the edition of the Gospels superintended by Fox the martyrologist, who, a memorandum in the title-page assures us, personally presented it to the Queen. There are numerous memorials of King James I. in books offered to him by the universities, the synod of Dort, &c.; and of his unfortunate successor there are the volumes of almanacs in which he scribbled his name when Prince Charles, and the beautifully bound volumes of the Protestant nuns of Huntingdonshire, the illustrated 'Harmony of the Evangelists,' probably one of the first books so illustrated, which was brought to him by Nicholas Ferrar in 1635, and of the king's delighted reception of which there is a minute account in the life of Ferrar. Among the books which belonged to Charles II., it would be startling, were it not known that the laws of copyright began in his time, to find a copy of the second edition of the 'Pilgrim's Progress,' a book of which, strange to say, there was no copy of any edition at all in the library of George III. The Royal collection comprised the entire libraries of some eminent individuals, which had been added to it at different times by donation or purchase;—of Archbishop Cranmer; of Henry, Prince of Wales, the elder brother of Charles I.; and of the great scholar Isaac Casaubon. There is an interesting account in the lives of eminent men by Thomas Smith, of the successful efforts of Patrick Young, King James I.'s librarian to keep Casaubon's collection in England. The royal library had several eminent librarians—Leland, in Henry VIII.'s time; Roger Ascham, in Edward VI.'s; Bulstrode Whitelocke, in the Commonwealth's; and in William III.'s, Dr. Bentley.

This collection, when added to that of Sir Hans Sloane, which was generally estimated at about 50,000 printed volumes, formed a library both of extent and value. It was soon augmented, in 1763, by a donation from George III., of a very remarkable character. In 1641, at the very outbreak of the Civil War, George Thomason, a bookseller of eminence in St. Paul's Churchyard, observing the turn which public affairs were taking, and the extraordinary activity of the press, conceived the idea of collecting all the pamphlets and publications on either side, from folios to broad-sides, as they made their appearance. Never was an idea of the kind more fortunately timed, and never more perseveringly and thoroughly acted upon. For the twenty years following, though we are told it was a heavy burden to himself and his servants, and though at one time it was thought advisable to effect a colourable sale of the collection to the University of Oxford to save it from the Commonwealth, the design appears to have been never relinquished for a day. On one occasion, the King himself sent to borrow a pamphlet, and chancing to drop it in the dirt, sent a courteous apology to Thomason, who made a memorandum of the circumstance in the volume (one with the press-mark C 21 b, which contains Shawe's 'Broken Heart') on which the dirt remains to this day to attest the fact. The whole collection at last amounted to about 30,000 pamphlets, bound up in chronological order, in 2220 volumes. Ill, indeed, was the collector requited. In a statement bound up with his catalogue, and written apparently by his son, we are told that in his life-time, which lasted till 1666, he refused 4000*l.* for the collection, supposing that sum not sufficient to reimburse him. His heirs offered it to King Charles II. for purchase, and he appears to have directed the royal stationer Mearne to buy it on his account, it is not known for what sum, and afterwards to have granted as a favour permission to resell it, which the heirs of the Mearne family did not succeed in doing till they disposed of it in 1762 to King George

III., for 300*l*. The collection when presented to the Museum was known there by the name of the "King's Pamphlets," the name and merits of the collector who had displayed such sagacity, energy, and perseverance, having sunk into total oblivion.

The presentation of the Royal Library to the Museum by George II. had left his successor without a collection of books, and George III. felt the deficiency keenly. He purchased in 1762, for about 10,000*l*. a library of noted merit which had been collected by Mr. Smith, the English consul at Venice; and it is said that on an average about 2000*l*. a year were expended during his long reign of sixty years in the augmentation of his library, under the care of his illegitimate half-brother, Sir Frederick Augusta Barnard. The King himself took a lively interest in the collection, was well acquainted with its contents and arrangement, and amongst other signs of interest he showed in it was anxious to have a printed catalogue, which Sir Frederick Barnard, who lived till 1827, survived to make. No ordinary taste and judgment were shown in the selection of the volumes, in which modern history and polite literature formed the principal features; and not only was Germany well represented in both, a very unusual circumstance in an English library of the time, but the other northern countries were not overlooked, though the collections appear to have been principally made in a mass, a large number of Scandinavian books for instance being purchased at once of Thorkelin. The library was kept in a series of rooms at Buckingham House, the site which had once been proposed for the British Museum; and a view of some of the rooms which contained it will be found in Pyne's 'Royal Residences.' Some alterations which George IV. proposed to make in the building, are said to have suggested to him the idea of disposing of the library. The history of its donation is involved in some mystery. After all that has been said upon the subject by Mr. Ford in the 'Quarterly Review' (1850, v. 88, p. 143), and by Mr. Croker in 'Notes and Queries' (v. 4, pp. 155, 446), those will not err who believe that at all events enough was said of transferring it to Russia to occasion a rather energetic remonstrance on the part of Lord Sidmouth, at the instigation of Richard Heber. On January 15th, 1823, George IV. addressed a letter to Lord Liverpool, in these words: "The King, my late revered and excellent father, having formed during a long series of years a most valuable and extensive library, consisting of about 120,000 volumes, I have resolved to present this collection to the British nation." The number here stated is worthy of remark from the excellent illustration it affords of the way in which the extent of libraries is usually exaggerated. The select committee of the House of Commons had the books counted, and said in consequence, in their report, "The number of books in the library is about 65,250, exclusive of a very numerous assortment of pamphlets, principally contained in 868 cases, and requiring about 140 more cases to contain the whole." These pamphlets have been since bound in separate volumes, and now therefore the number of volumes in the library is much above that stated in the report of the committee. Notwithstanding all this discussion, in Timperley's 'Encyclopædia of Literary and Typographical Anecdote,' the edition of 1842, this very King's Library is described (at page 686) as "amounting to full 250,000 volumes in number."

In order to connect together the series of royal donations, we have stepped a little out of the order of chronological arrangement. Previous to the accession of the King's Library there had been two bequests of great importance, and each of them by trustees; the first, of the library as well as the other collections of the Rev. Clayton Mordaunt Cracherode, in 1799; and the other of those of Sir Joseph Banks, in 1820. Mr. Cracherode's collection amounted to about 4500 volumes in number, and was remarkable for the beauty, selectness, and fine condition of the books which composed it; Sir Joseph's amounted to about 16,000 volumes, and was a working library, consisting almost entirely of books on natural history and of voyages and travels, the principal extrinsic value of which consisted in the fact that in a large number of cases they were presentation copies from the authors. A minute analytical catalogue of the natural history portion of the library, which was published by the librarian Dr. Dryander, a Swede, in 1799—1805, has always been regarded as one of the best bibliographical works on natural history. Sir Joseph had previously presented to the Museum two or three collections of Icelandic works obtained during his visit to Iceland, and one of which comprised the collection of Halldan Einarsson, author of the literary history of Iceland. By his will he left the library in the first instance to his librarian, Mr. Robert Brown, and only after his death to the Museum. As Mr. Brown survived to the year 1858, the effect of this disposition would have been not only to deprive the Museum of the benefit of the bequest for nearly forty years, but during that time to prevent the national library from even purchasing a copy of any of the books which composed the Banksian, under penalty of procuring a prospective duplicate. Fortunately an arrangement was entered into by which the Museum acquired in the person of Mr. Brown one of its most distinguished officers, as the keeper of the Banksian collection, and the library was in 1827, transferred to the national establishment. Both the Cracherode and Banksian collections are still kept entirely distinct in apartments which, although they contain other portions of the library in addition, are known by the name of the Cracherode and Banksian rooms.

Of smaller acquisitions there were many of value. Dr. Thomas

Birch, one of the most active of the early trustees, bequeathed in 1766, his library, which abounded in historical and biographical matter. Sir William Musgrave, another trustee, made, in 1799, a bequest of all such of his books as were not previously in the British Museum—a most valuable form of bequest which was afterwards imitated by Mr. Tyrwhitt, and which if it were followed out by other collectors would be of the greatest possible benefit to the national library and the least injury to the heirs. Sir William had previously presented in 1790, a large collection of pamphlets on English biography, his favourite pursuit, as is shown by his manuscript catalogue, also in the Museum, in many folio volumes, of the names of persons deceased, with indications of where notices of them had been published, a valuable book of reference to biographical compilers. The collections of the two rival historians of music, Sir John Hawkins and Dr. Burney, were finally united at the Museum, that of Sir John coming in 1778, by donation, that of Dr. Burney in 1815 by purchase. The bequest of Mr. Tyrwhitt, the editor of Chaucer, in 1786, added a fine collection of about 900 volumes of classical, and also of Italian and Spanish authors, including about 300 of the plays of Lope de Vega. The fine collection of old English plays which had belonged to Garrick was acquired in 1780, by purchase, from the widow of the great actor. A library of law books, including many rarities, was bought in 1813, of Francis Hargrave, an eminent barrister. In 1807, when Cumberland, the author of the *West Indian*, had sold to a bookseller about eighty volumes of the classics which had belonged to his relation, the great Dr. Bentley, and were enriched with the Doctor's manuscript notes, the circumstance fortunately became known to the librarians of the Museum in time to enable them to acquire these volumes for the national collection for the sum of 400*l*.

About this period several entire libraries were purchased. In 1815, a deputation of two of the officers of the Museum, the Rev. H. H. Baber and Mr. König, was sent to Munich to examine the library of 20,000 volumes, chiefly of natural history and medicine, belonging to Baron Moll, which was purchased at their recommendation. In 1818 nearly five thousand volumes of miscellaneous Italian and French were bought at once of the heirs of M. Ginguené the historian of Italian literature. In the same year another whole collection was obtained, and in this case an English one, the library of Dr. Charles Burney of Greenwich, the classical scholar, and son of the Dr. Burney whose musical collection had been acquired three years before. It had three distinguishing features—a collection of interleaved copies of the Greek classics with manuscript notes, another of materials for the history of the stage, consisting of printed playbills and manuscript memoranda; and another of about 700 volumes of newspapers from the earliest period to the passing day. The great prize was considered to lie in the interleaved classics, some of which are of value, and others were afterwards found to be chiefly interleaved with blank paper, or paper presenting only various readings copied from different editions in the handwriting of the doctor's pupils. The materials for the history of the stage have chiefly been turned to account by the plodding industry of one man, the Rev. John Genest, who worked at them for years, and whose anonymous 'History of the English Stage,' in 10 volumes, is chiefly filled with the dates and "casts" which they supply. The collection of newspapers, which was valued at a thousand pounds of the 9000 guineas which the printed books of the Burney collection cost, was looked on with little favour, and in the application to the House of Commons for the grant, it was considered advisable to veil this part of the collection in some ambiguity. Since Naudé had pointed out the usefulness of preserving pamphlets, that kind of acquisition had been in favour with many collectors, and it was the great boast of the Harleian library of printed books that it contained 400,000, but no one had yet pointed out the utility of preserving newspapers. The Museum was already in possession, from the bequest of Dr. Birch in 1766, of a publication called 'The English Mercury,' bearing the date of 1588, and which since 1796, when George Chalmers first called attention to it, had been looked upon not only as the first English newspaper, but the first in the world—an honour which it was destined to lose in 1839, when Mr. Thomas Watts, in his 'Letter to Antonio Panizzi, on the reputed earliest newspaper,' proved beyond dispute that it was a fabrication, which was subsequently shown to have originated, probably in a frolic, with one of the sons of Lord Hardwicke, the Chancellor, and with Dr. Birch, who was the friend of the family. The newspapers of Dr. Burney's collection comprised many of the earliest genuine specimens extant, and to some minds few of the objects in the British Museum are more interesting than the contemporary newspapers which describe the trial and execution of Charles I. Long neglected and almost unnoticed in Knight Hunt's history of English newspapers, called 'The Fourth Estate,' the newspapers of the Burney collection, have lately been partly brought to light in Andrews's 'History of British Journalism,' but still contain much that is curious, and yet awaits a chronicler. Those, for instance, who suppose that leading articles are a comparatively recent invention, may be surprised to find in the newspapers of 1649, leading articles written in a Miltonic vein, and advocating the execution of the king. The collection is indeed imperfect; the early numbers of the 'Morning Chronicle' are not to be found either in the Museum, or so far as is known elsewhere, and when Sara Coleridge was anxious to reprint her father's essays on contemporary politics from the columns of the 'Morning Post,' she consulted the Museum in vain.

The acquisition of the Burney collection, led however to an arrangement which will save future inquirers from similar disappointments. From 1818, the Stamp Office was directed to supply to the Museum its copies of London newspapers after the lapse of two years, a lapse which had previously converted them into a "perquisite," and consigned them to destruction. The English country newspapers were afterwards added, from about 1820; the Scotch from 1844; the Irish still later, but with the set beginning in 1823; and there are signs that the colonial will follow, while numerous sets of continental and American newspapers have been added at different times, and others are adding. On the ground floor in the new library, which surrounds the reading-room, large shelves of newspapers occupy two sides of a circular passage about 600 feet in length, and the space required is rapidly extending. 'The Times' alone, is now obliged to be bound in twelve folio volumes *per annum*.

Of smaller collections, it should be mentioned that Sir Richard Colt Hoare made in 1825 a most valuable present of books on the topography of Italy, which he had acquired in that country during a visit at the close of the 18th century. Four distinct assemblages of tracts on the French revolution were acquired by purchase, said to amount to about 50,000 articles, and forming collectively a sort of pendant to the Thomason collection. They form the groundwork of Louis Blanc's new 'History of the Revolution.' The Burney library was the last of importance that was acquired in a mass, by purchase; but in 1846, the most valuable addition that had ever been made to the library at once, with the exception of the "Georgian" library, was made by the bequest of the Right Hon. Thomas Grenville. Mr. Grenville, who had signed the treaty of American independence in 1783, died in the full possession of his faculties at the age of nearly ninety-one, in 1846. In a codicil to his will, dated in October 1845, he expresses himself thus: "A great part of my library has been purchased from the profits of a sinecure office given me by the public, and I feel it to be a debt and a duty that I should acknowledge this obligation by giving that library, so acquired, to the British Museum for the use of the public." The collection comprised 20,240 volumes, and had cost more than 54,000*l.*, it was in admirable condition in all respects, abounding in fine bindings, in copies on vellum, and on large paper, and was altogether such a library as Dibdin delighted to describe. It was rich in choice Italian and Spanish literature, and in early voyages and travels, and in many respects dovetailed admirably with the Museum collections: the Museum, for instance, having few early editions of the 'Orlando Furioso,' or of 'Don Quixote'—the Grenville being remarkably complete in both. This, however, was the less remarkable as the intention of the donor had been confided some time before his death to his friend Mr. Panizzi, the keeper of the printed books. This fine library is kept entirely apart in a room, which contains a bust of its donor, and it has a separate printed catalogue.

Long before the fortunate acquisition of the Grenville collection, a great change had taken place in the management of the national library. Before the committee of the House of Commons on the Museum, in June 1836, Mr. Panizzi, then the second assistant librarian in the printed book department, had excited much surprise by what was considered the daring nature of his proposals. The Rev. H. H. Baber, then keeper of the printed books, had incidentally mentioned in his evidence a few days before, that the library committee of the trustees had given up holding meetings, because at one time the funds appropriated to the augmentation of the library had sunk so low as 200*l.* a-year. The sum expended on the collection of printed books had risen in 1836 to about 2000*l.* a-year, but this did not satisfy Mr. Panizzi. Lord Stanley, now (1859) Earl of Derby, who was one of the members of the committee, said to him, in a tone of sarcasm, "In short, for the accomplishment of your views you would desire first an annual grant to the amount of more than 12,000*l.* a-year for the library; next the institution of two or more libraries for the use of the public, with somewhat different views, in London; and thirdly, the removal from the British Museum of the natural history department for the purpose of affording extra space for the increased library." "Not only space," replied Mr. Panizzi ('Report of Evidence,' p. 392), "but the extra assistance which is requisite. The public have a right to expect something worthy of the nation, and I trust that this committee will see the absolute necessity of recommending something like what I have had the honour to suggest, and not less." This dialogue contains a remarkable foreshadowing of the future tendencies of the Museum, and others hardly less remarkable are to be found in the series of letters already cited, which appeared in the 'Mechanics Magazine' about the same time, from the pen of Mr. Thomas Watts. Mr. Watts strongly advocated the filling up of numerous gaps in foreign literature, which he pointed out. "It is not too much to say," he observes in an article in the Magazine for 1836 (vol. xxv. p. 77), "that there must be at least 100,000 volumes on the shelves of book-sellers in Europe, which deserve a place in the Museum, and might, were money liberally granted and proper spirit exerted, at once be transferred there. The British Museum should regularly take in, at least one literary journal from every country in Europe, containing reviews and announcements of new publications. It should be part of the duty of the librarian to peruse these, and to make a note of every work that seemed worthy of admission to the library, these might

then at once be ordered from the places of publication. . . . A constant supply of foreign literature would then be pouring in." In 1837, Mr. Panizzi became keeper of the printed book department, and on January 1838, Mr. Watts became one of his assistants. Mr. Watts had the satisfaction not only of finding his plans for the augmentation of the library approved, but of seeing himself gradually empowered to carry them out in person. Lists of all the current publications, not only in French and German, but in Spanish and Portuguese, Swedish and Danish, Dutch, Russian, Polish, Hungarian, &c., were and are procured as abundantly as practicable, and inspected by him for the purpose of marking the books to be purchased for the Museum.

The result was satisfactory. In 1843 Mr. Panizzi commenced a minute examination into the general deficiencies of the library, assisted by Mr. Jones and Mr. Watts, and in 1845 laid an elaborate report on the subject before the trustees. Unusual stress is laid in this report, on the literature of the modern foreign languages. "To be acquainted," it is said, in one passage (page 25), with the national history, laws, literature, and scientific knowledge of the Dutch or Hungarians, of the Swedes or the Danes, cannot be an object of less importance and practical utility, than to be familiar with the history, laws, &c., of the Egyptians, the Phœnicians, or the Etruscans." The deficiencies in French, Italian, Spanish, and German literature were strongly pointed out, and also those in English. "The Museum," it was remarked, "does not possess the laws, ordinances, or government acts of one-half of the dependencies of England." "With respect to English literature, or indeed any branch of English knowledge or science, the British Museum ought to afford every assistance, and the want of any English book in such an institution ought to be a rare occurrence." To improve the state of the library, Mr. Panizzi proposed a largely increased annual parliamentary grant; the trustees applied for that purpose to the Treasury, and the Lords of the Treasury recommended to Parliament "an annual grant of 10,000*l.* for some years to come, for the purchase of books of all descriptions." The effects of this liberality were of course soon visible. The number of volumes added to the library of printed books in 1845 was 12,163; in 1846 it rose to 31,848; and in 1847, aided by the 20,000 volumes of the Grenville library, it was no less than 55,475. In 1848 it was 22,056 but in 1849 it sunk to 14,266, and in 1851 was only 11,492, or little more than a third of what it had been five years before. The vast increase of volumes led of course to increased requirements for binding and cataloguing, and, above all, for space. As it was considered useless to purchase what room could not be found for, and thus lead to complaints that books in the Museum were not accessible, the grant was reduced to 4500*l.*, and even less; and it was only after the erection of the new library, which was completed in 1857, that the large scale of grants and purchases was resumed. In the estimates for 1858, and in those for 1859, the sum of 10,000*l.* is again set down for printed books.

The magnitude of the effects of the impulse given in 1845 is best shown by a statement of the number of the volumes in the library, before and after. "The library," says Mr. Jones, the present keeper, in his 'Guide to the Printed Books,' dated February, 1858, "has been twice counted; the first time on the 25th of July, 1838, when the number of printed volumes was found to be 235,000, and again on the 15th of December, 1849, at which period they had increased to 435,000. They are now about 550,000, and the annual increase is not less than 20,000 volumes." The total number of volumes added in 1858 was 32,152. It may be added, that in the year 1821, before the accession of the King's Library, the number of the national collection was stated at less than 116,000; and that probably, at that period, the belief was more prevalent than it has ever been since among the public in general, that "the library of the British Museum contained a copy of every book ever printed." There is perhaps no better symptom for the prospects of the library, than that this belief has become less confident in the exact proportion that it has become less absurd, and that at present the librarians of the Museum are the first to acknowledge, that whatever the comparative merit of the collection, it is still far from being what it ought to be in point of attainable completeness. In every branch of learning in which a student commences to prosecute real research at the Museum, he will soon discover, even now, that considerable gaps exist.

The state of the library is, nevertheless, very different from what it was twenty years ago, and it now stands perhaps second in the list of the great collections of Europe. The libraries of France and Italy and the South have in general founded their claims to admiration on such merits as Dr. Dibdin gives most importance to—the rarity and beauty of particular volumes contained in them, their general good condition, and their extent. In the libraries of Germany, Scandinavia, and the North in general, on the other hand, more attention has been paid to scientific completeness, and to excellence of cataloguing and arrangements. Copies on vellum or on large paper, or in remarkable bindings, sets of Alduses or Elzevirs, have been amassed in the one; complete sets of books on a particular subject, well classed, in the other. In the Museum there is a combination of both these claims. The King's library, both old and new, the Grenville, and the Cracherode collections, would alone suffice to place it on a high level in point of rarities and curiosities, and there has been no falling-off in purchases of this kind during the administration of Mr. Panizzi and his successor, Mr. Winter Jones. The Roxburghe ballads, early editions of the Bible, early Service

books, early editions of Shakspeare's plays,—everything that is rare and curious has been secured whenever an opportunity occurred. In the early part of the 19th century, when bibliomania was so prevalent, the name of the British Museum was scarcely heard in a sale-room; of late years its agents have been incessantly active. While thus increasing in splendour, the library has been equally increasing in usefulness. For the first time in the history of literature, an attempt has been made on a large scale to bring under one roof all the current literature of the world that had any intrinsic value, regardless of the language in which it might be couched. Mr. Watts, in his proposals, spoke of "one journal from every country in Europe;" and at the time he wrote there was no journal in the Museum in the Russian language: the catalogue now contains eighteen. The Museum is now supposed to possess the best Russian library in existence out of Russia; the best Hungarian out of Hungary; the best Dutch out of Holland;—in short, the best library in every European language out of the territory in which that language is vernacular. The books are in every case the standard books of the language,—the laws, the histories, the biographies, the works on topography and local history, the poets and novelists in most esteem;—in short, all that moulds or paints the life and manners of a nation, and which now a student of any European language need travel no farther than to the reading-room of the Museum to see and make use of.

The literature of the English language in the United States was another point that engaged attention, and orders were sent out as early as 1839 to America direct. At present the number of American books in the Museum is greater than in any library of the United States. A separate catalogue of these books has been prepared by Mr. Henry Stevens, the American agent who has had the largest share in procuring them, and it fills two octavo volumes, printed in double columns, which have not as yet been issued to the public.

For the augmentation of the collection of English books reliance had been placed, in the earlier stages of the Museum, on its legal rights. The donation of the Royal Library to the Museum by George II., in 1757, was accompanied by that of the royal privilege of gratuitously receiving from the publishers a copy of every work printed in the English dominions. This had first been granted to the Crown by an Act of Parliament of the 14th of Charles II., and subsequently renewed after expiry by the famous Copyright Act of the 8th of Queen Anne. Dr. Bentley, when keeper of the Royal Library, complained of the constant evasion of this Act by the booksellers; and the complaints were often renewed by the librarians of the Museum, though from about the year 1818, when Mr. Baber, then keeper of the printed books, gave some curious evidence on the subject before the Copyright Committee, there was certainly a great improvement. The new Copyright Act of 1842 gave a pre-eminence to the Museum among other libraries to which the privilege was conceded, and provided that in case of non-compliance with the Act the negligent publisher might be taken before a magistrate and fined. In 1850, the superintendence of this part of the Museum business was transferred to Mr. Panizzi, as keeper of the Printed Book department, and the strictness with which he enforced the Act led to a great augmentation in the number of books received. At present all is collected that issues from the English press down to the most insignificant work on crochet, to a Child's Missionary Magazine, the directory of a country town, or a circulating library novel; and everything that is collected finds its place on the shelves and in the catalogue, in the conviction that it may often be a point of importance to preserve one copy of even a worthless work in a repository where it may instantly be referred to in case of need. A different system prevailed in former days, when it does not seem to have struck a single individual that it might probably be of advantage to preserve a set of the 'London Directory' or the 'Navy List,' and a complete collection of either is, in consequence, not to be found in the British Museum or apparently anywhere else.

The Oriental collections of the Printed Book department have not yet been mentioned. In 1759, the year of opening, a choice and valuable collection of 180 Hebrew volumes in the binding, apparently executed for King Charles II., whose marks it bears, was presented by Mr. Salomon da Costa. No considerable additions were made to the Hebrew till 1848, when Mr. Panizzi purchased a selection of 4420 volumes from a library of Hebrew, which had been formed by Mr. H. J. Michael of Hamburg, and purchased entire by Mr. Asher, the learned bookseller of Berlin, the most able and zealous of the continental purveyors for the Museum. In 1836, a collection of the works in Armenian, published by the Mechitarist monks of Venice, was purchased by Mr. Baber; to this, considerable additions were afterwards made, including, among other works, a book that would hardly have been looked for in Armenian, a translation of 'Uncle Tom's Cabin.' It may be worth while to mention that advantage has been taken of the polyglot popularity of Uncle Tom's Cabin, to afford students an opportunity, not otherwise procurable, of studying the colloquial and familiar idiom of different countries. Versions have been procured or ordered in almost every European language, and there are some, Welsh and Wallachian for instance, in which there are double or triple versions of this particular book, while there is hardly a double version of any other except the Bible. The collections of Arabic, Persian, and Turkish, at the Museum, as well as of Sanskrit and the other Indian languages, are very susceptible of improvement,

but of Chinese there is a large collection. One bequeathed in 1825, by Mr. Fowler Hull, forms the nucleus; many other volumes were afterwards selected and purchased on different occasions, and in 1847 the collection of Chinese books belonging to Mr. Morrison the younger, amounting to 11,500 volumes, was purchased by government and presented to the Museum. In Chinese literature the library may now, therefore, be considered at least on a level with any other in Europe, and no opportunity has been lost of procuring specimens of the Mongolian, the Mantchoo-Tatar, and other languages of Eastern Asia.

The maps and music are collections both of which are connected with the Printed Book department, and both of which are in a course of development unknown to them twenty years ago. The collection of maps in the King's Library is a remarkably rich one, accompanied with a large collection of topographical prints and drawings, and is arranged in more than 100 folio volumes. The music was formerly confined to that received by privilege only, in addition to the works acquired by the purchase of the library of the elder Dr. Burney, and received by the donation of Sir John Hawkins. It has now extended to more than 4000 volumes, and is still extending.

The catalogue of the British Museum has been a subject of frequent discussion in the public press, since the committee of the House of Commons in 1835. Before that time, in 1824, the Rev. Thomas Hartwell Horne had been appointed to superintend the preparation of a classed catalogue; but in 1834 his labours and those of his colleagues had been suspended, and the Rev. Mr. Baber had been directed to draw up plans for an alphabetical catalogue. A long correspondence on the subject will be found in the Appendices to the Reports of the Commons' Committee and of the Royal Commission. When, after Mr. Panizzi's appointment to the keepership, the library had been removed from the old to the new building, the question of cataloguing and of printing the catalogue again came up; and a small committee of the Printed Book Department, presided over by Mr. Panizzi, drew up in 1839 a series of rules for that purpose, which amounted, when they finally received the sanction of the trustees, who re-discussed them, to the number of ninety-one. Objection has been made to their number; but it must be remembered that it was requisite to provide beforehand for all the contingencies to be foreseen in operating on a large library by several hands; and experience shows that the variety in the notions of cataloguers is wonderful. In the King's Library catalogue, for instance, though it is professedly alphabetical, all the novels and tales by anonymous authors, from Amadis de Gaul to Waverley, are entered in a mass, under the singular heading of 'Fabulæ Romanenses.' In such a title as the 'Second Report of the Auxiliary Trinitarian Bible Society of St. James's, Clerkenwell,' there is hardly a word, except the particles, which has not been selected by some cataloguers as a heading, many taking even the word "Second;" though it is evident that, on that principle, a set of twenty of these reports would figure in twenty different parts of the same list. It is evident that difficulties of this kind do not diminish when foreign languages are to be treated, which, in the case of the Museum library, are not few in number. A commencement was made of printing the catalogue compiled on the new principles, and in 1841 the first volume, containing the letter A, appeared under the superintendence of Mr. Panizzi; but immediately afterwards the printing was suspended, and one of the objects of the royal commission of 1847 was to inquire into the cause of this suspension. The commission approved of the step which had been taken, for the reasons assigned by Mr. Panizzi, that it was eminently unadvisable to print any portion of an alphabetical catalogue before the whole was ready for the press. Since this decision has been arrived at, the revision of the old catalogue has continued in manuscript, while all the fresh books added have been dealt with on the same principles; but, as has already been stated, the number of volumes in the Museum before the year 1839 was about 235,000, while the number since added exceeds 335,000; so that the bulk of the supplements, had the catalogue been printed, would in 1859 have already exceeded that of the principal. The immense labour expended on this gigantic work would perhaps have been more highly appreciated by the public, had some of its results been embodied in print. The knowledge and care required in settling the items of an extensive catalogue might often win a reputation if exerted in some other direction, but apparently will never in England win a reputation in this.

When a new book has been catalogued, the next step to be taken with it is to place it on one of the shelves in a press or book-case, that it may receive its appropriate "press-mark," that is, the indication of its locality. At the Museum each press or book-case has a certain number, and the different shelves are indicated by the letters of the alphabet. Thus the press-mark '1340 a,' indicates that the book is placed on the 'a' or topmost shelf of press or book-case 1340. Nothing can be more simple, yet this simplicity is rare. In another library in London, for instance, the system is exactly reversed, the presses are marked with the letters of the alphabet, and the shelves with numbers; the consequence is, that as the letters of the alphabet are soon exhausted, the librarians have to commence a second series by repeating them thus, AA, BB, &c.; then a third and a fourth on some other principle, and long before they have arrived at as high a number as 1340, the system is involved in inextricable entanglement. As the shelves in any book-case never amount to the number of

the letters of the alphabet, no difficulty of the kind can occur with them. Yet the system of numbering the presses appears to have been slow in suggesting itself to librarians in general; Sir Robert Cotton named his book-cases after the Twelve Cæsars, and in order to find a book it was necessary to remember the succession of Otho, Vitellius, and Vespasian. When his book-cases outgrew the number of twelve, he abandoned even this system for a worse, and instead of proceeding in succession with the "five good Emperors," arbitrarily introduced Cleopatra and Faustina. At the Advocates Library in Scotland, the presses were patriotically named after the succession of the Scottish kings, then the additional ones after the signs of the zodiac, &c., till necessity drove them to the adoption of numbers, lest they should be compelled to make every new attendant go through a small course of the sciences before he could find a book. The great problem in the arrangement of a library, which is increasing, is so to place every book as it comes in, that it may receive a press-mark which will never have to be altered, and yet to provide that the classes of books shall be kept together; that a new book of travels in Australia, for instance, shall stand with other books of travels in Australia, and not with Spanish plays or the Acts of Parliament. A system of this kind would seem to be peculiarly difficult to establish in a library which is increasing at the rate of 20,000 volumes a year, and yet at the Museum a plan of extreme simplicity has been adopted, which is found to answer its purpose. Let us suppose that a room has been built which contains 100 book-cases, each capable of containing 150 volumes, and therefore that the room will contain 15,000 volumes in all, but that the possessor has 1000 volumes only to place in it at the outset, intending to purchase for the next fourteen years 1000 volumes a year. It is evident that if he numbers his presses from 1 to 100, and proceeds to place his several books, the very first few volumes that he marks with a press-mark hamper him in a certain degree as to the places of all the others. If he assumes that his purchases of books in English history will finally occupy a single press, and therefore places an edition of Hume in press 77, and occupies press 76 on one side of it with ancient history, and press 78 with the history of France; he may find a year after that his purchases in English history have filled press 77, and in French history press 78, and that he requires more room for both, but that the only space he has left is in press 2 among the bibles, or in press 99 which is entirely vacant, but stands next to the works of Shakspeare. The order which he has endeavoured to preserve is therefore spoiled: he must either fill up the vacant spaces with incongruous books, or shift the position of a number of them and alter the press-marks. The problem will be certain to recur over and over again before the room is filled, and each time the remedy will be more hard to effect and more wearisome. One simple change of feature in the arrangements adopted at the outset will obviate all the difficulty. We have supposed that he has marked his presses with fixed consecutive numbers from 1 to 100; let us suppose that he marks them instead with moveable numbers not consecutive, leaving gaps between, and the whole trouble is got over. Assume, for instance, that he places his Hume just in the same position but marks the press 283, and places the French history still in the next press, but marks that press 315. When, in the course of a year or two, he finds that he wants additional room for English history, and that the last press but one in the room is vacant, he removes the contents of the last press but two into the last press but one, removing the number with it, and by repeating the process obtains a vacant press immediately after his press of English history, which is exactly what is required. The new press between 283 and 315 he marks with some intermediate number. The process can be repeated as often as requisite, and the gain is obvious; the press-marks remain the same, and, though not consecutive, they stand in sequence, and serve as a ready and easy guide. The books are moveable, and yet the press-marks are permanent. The processes we have supposed are precisely those which have actually occurred at the British Museum. When, in 1838, the old library was moved from Montague House to the new apartments in the northern range, the press-mark of every book, and every tract in a book (of which there are sometimes more than a hundred in a volume), was altered. The task of arranging the library in its new position was entrusted to Mr. Watts, who in the course of that and the eighteen following years, during which every book that entered the Museum passed through his hands, must have examined and classed upwards of 400,000 volumes. The rapid augmentation of the collection, and the system of marking the presses with consecutive numbers, made it necessary that the accumulations should be arranged in three successive sets or series. The idea of the plan of inconsecutive numbers occurred to Mr. Watts long before it could be carried into effect, as to exercise it, it required that all, or nearly all, the presses should be of similar height and size, and the presses in the new building often varied considerably. The new scheme, on receiving the sanction of Mr. Panizzi, was finally commenced in the long room by the side of the King's Library. The presses in that room amounted to about 600, but in the numbering a range of numbers was assumed from 3000 to 12,000. The numbers from the beginning of 3000 to the end of 4000 were assigned to Theology, from 5000 to 6000 to Jurisprudence, from 7000 to 8000 to Philosophy, Science, and Art, from 9000 to 10,000 to History, from 11,000 to 12,000 to Literature. A particular subdivision was assigned to each "century" of numbers; it was assumed, for instance,

that dramatic literature would occupy a hundred presses, from 11,700 to 11,799, and thus every drama which has been "placed" on the new system bears in its press-mark 117 for the first three figures of the five. This system, which is known by the name of "the elastic system," appears to promise several advantages besides those which have been already derived from it. It is evident, for instance, that if one copy of the title-slips of the books thus placed and marked were arranged in the order of the press-marks instead of that of the authors' names, it would *ipso facto* produce a rough classed catalogue; and thus a problem which has been thought insoluble would be solved in the simplest manner.

When the title-slip of a new book has received the press-mark of its locality, it is ready to be entered in the manuscript catalogue, and passes therefore into the hands of the "Transcribers." The present catalogues of the Museum are as novel as many other of its arrangements. Formerly, the titles were simply written into an interleaved copy of the printed catalogue, a copy of which was kept in the reading-room. As it could not be calculated beforehand what the insertions were to be, the same difficulty was perpetually recurring with the alphabetical order of the entries as with the classified arrangement of the books, and the only remedy in use was to cancel a sheet whenever required, and re-write the entries over a larger space. The system was not found adequate to the requirements of the Museum, when the augmentations rose to the rate of 20,000 volumes a year. The present system is that of using prepared paper and a kind of "stylus," so that four copies of each entry are produced at once. These copies, which are necessarily on thin paper, are mounted on thicker paper by the bookbinder, so as to be equal to considerable wear and tear, and are then fastened on the pages in the volumes of the catalogue, in such a way that, if required, they can be readily taken up again and removed to another page. By this means the exact alphabetical arrangement of the catalogue is continually kept up, to the great advantage of the readers who consult it. This system is found in action in the long array of volumes, now (June, 1859) about 900 in number, which occupy one of the central stands in the reading-room, and contain a consolidated list of all the collections in the Museum up to as far as the letter G in the alphabet, and beyond the letter G, the augmentations of the years since about 1850. It is also applied to the separate catalogues of the collections of maps and music, a series of which also stands in the reading-room, amounting respectively to 79 and 52 volumes. In addition to the catalogue in 900 volumes, the reader who does not find in it a work that he requires of an older date than 1849, and of which the author's name begins with one of the letters of the alphabet that come after G, should consult the 'Old Catalogue,' in 82 interleaved volumes, the catalogue of the King's Library, and the catalogue of the Grenville Library, all standing side by side in the reading-room, in the circular book-stands towards the centre.

The Grenville Room and the King's Library are now made use of for the purpose of exhibiting to the general public a selection of the most interesting curiosities of the library, a notice of which will perhaps be most appropriate here. A selection of this kind had long existed in the "show-cases" and "select cases" of the interior of the library, but was not made public till the "Great Exhibition year" of 1851, and after that period was again closed, till the book-cases of the King's Library having been glazed to protect the books from dust, that magnificent room was again opened to the public, in conjunction with the Manuscript and Grenville Rooms, at the suggestion of Mr. Panizzi. The books now shown occupy fourteen cases, the contents of which are described in a 'Guide to the Printed Books,' by Mr. Winter Jones, sold at the Museum. A series of no less than twenty-four block-books and impressions from early blocks is exhibited, forming as valuable a collection as any perhaps in the world, with the exception of that of Munich. They include four editions of the 'Biblia Pauperum,' and the edition of the 'Book of Canticles,' which is so important to inquirers into the early history of printing, from its bearing a Dutch inscription, the authenticity of which has been doubted, but will be doubted no longer by those who see this copy. We find also the broadside entitled 'Temptationes Demonis,' of which no other specimen is known; the other copy once supposed to have existed being now identified with this; and the 'Speculum humanæ Salvationis,' supposed to have been printed by Koster. The Latin Bible known as the 'Mazarine Bible,'—the earliest book that was ever printed, according to the general belief, and certainly one of the finest,—is there, in company with the Latin Psalter of 1457, printed by Faust and Scheffer, the earliest book that bears a date, and renowned for the splendour of its initial letter, printed in colours. The first book printed in Italy, and the first in France, are shown, as well as the first book printed in England, 'The Game of the Chesse,' executed by Caxton at Westminster Abbey in 1474. It is said, in Walter Scott's 'Antiquary,' that the copy there described by Oldbuck as having been acquired by "Snuffy Davy" at a stall in Holland, for the "easy equivalent of twopence sterling," is the very same copy that passed into the library of George III.; but this appears to be a mistake. The King's copy of the 'Recuyell of the Histories of Troye,' of the date of 1471, the first book printed in the English language, was bought for the royal collection at a sale in 1773 for 32*l.* 11*s.*; while at the Roxburghe sale, in 1812, a similar copy sold for 1068*l.* 18*s.* It lies in the show-case by the side of the French book of which it is a translation, also

printed in Caxton's types, and considered to be the first book printed in French. Specimens of illuminated printing, and of illustrations on wood and copper-plate, fill some of the other cases; and one is devoted to specimens of binding. In this are shown beautiful proofs of the taste of Grolier and Maioli, and also volumes of remarkable binding that have belonged to King Henry VIII., Queen Elizabeth, and Mary, queen of Scots, and show the taste of the times. A walk through the King's Library, and an inspection of the treasures it contains, are in themselves a small course of bibliography.

A history of the reading-room of the Museum is now in course of preparation by Mr. Winter Jones, to be prefixed to a printed catalogue of the books it contains, which has been some time preparing for the press. The number of visits to the reading-room has undergone an increase similar to that to the Museum in general. The regulations for its management at the outset, in 1759, were of the same cautious and restrictive character with those for the general establishment. After some stringent rules with regard to admission, it was ordained (Regulation 3) "that a particular room be allotted to the persons so admitted, in which they may sit and read or write without interruption during the time that the Museum is kept open; that a proper officer be constantly present in the said room as long as any such person or persons shall be there; and for the greater ease and convenience of the said persons, as well as security of the collection, it is expected that notice be given in writing the day before by each person to the said officer, what book or manuscript he will be desirous of perusing the following day, which book or manuscript, on such request, will be lodged in some convenient place in the said room, and will from thence be delivered to him by the officer of the said room; excepting, however," &c. &c. Gray, the poet, was one of the first to avail himself of the opening of the room, and some mention of it, in his usual tone of splenetic humour, is to be found in two or three of his letters. "I often," he writes, in August, 1759, "pass four hours in the day in the stillness and solitude of the reading-room;" and in another letter he describes the company, which at that time consisted of only four other readers, two of whom were Prussians, while Dr. Stukeley, the antiquary, and a copyist made up the number. Foreigners and antiquaries appear to have continued to be frequent visitors, and towards the close of the century, French emigrants almost outnumbered the native English. D'Israeli the elder, in the last edition of his 'Curiosities of Literature' which he superintended, gave a few lines to his reminiscences of the quiet old room. In 1803, almost simultaneously with the death of Dr. Penneck, who had been for forty-two years keeper of the reading-room, several alterations in the arrangements were made, and the old room was changed for a new one. Peller Malcolm, in his 'Londinium Redivivum,' published at that time, gives a description of both. "The reading-room, till the winter of 1803, was," he says, "a large vaulted apartment with a clumsy marble chimney-piece, but having only two windows, which were insufficient to illuminate the most remote parts of the table." "The present reading-room," he continues, "is surrounded by shelves of books secured by wire, has a vaulted ceiling, a handsome cornice, and a large marble chimney-piece, &c. &c. Two long tables extend north and south, on each side of the fire-place, for the readers; these are covered with green cloth, and are plentifully supplied with pens, ink, and rests for the books. Catalogues are placed on shelves within the room, which the reader consults at pleasure, writes his notes from them, pulls the bell-rope near the door, a messenger instantly obeys the summons, and in as short a time as possible returns with the wished-for book." By the rules promulgated in 1803, no reader, except in particular cases, at the discretion of the principal librarian, was entitled to more than two volumes at a time, but they might be exchanged as often as he required. As the library and the metropolis both went on increasing, so did the visitors to the reading-room. "At the time when these buildings were first under consideration," said Sir Robert Smirke, in his evidence before the Committee of 1836, "it was stated to me by one of the principal officers of the Museum, that the average number of readers daily attending the rooms was 30. He stated at the same time that he thought it probable, if more convenient arrangements were made for their reception, they might be increased to 80, or even perhaps 100. There are now frequently 200, and yet more accommodation is wanted." This accommodation was provided in the new buildings, first in two temporary rooms in the south-east corner, to which access was gained by a steep flight of steps, and after 1838, by two rooms in the north-east corner, built expressly for reading rooms, but to which the entrance was by a door in the basement. There were parts of the principal room in which reading was impracticable at certain times of the day till some alterations were made, by perforating the gallery above, introducing reflectors, &c., which at last shed sufficient light on the tables below. As the number of readers increased, additional tables were introduced, which had, however, the effect of making the passages between inconveniently narrow. The ceiling of the reading-rooms being only 31 feet high, the ordinary height of the apartments on the principal floor, the atmosphere, when the attendance of readers had been numerous, became oppressive and disagreeable towards the close of the day. These considerations made the readers welcome with a pleasure mixed with surprise the news that the splendid reading-room was in progress, which was finally opened to them on May 20th, 1857. Some description of this room has already been given

in our account of the building. The number of readers instantaneously doubled, and the daily average in 1858 was 424. Many of these are ladies, for whose exclusive accommodation there are tables affording fourteen seats, while they are always at liberty to take a seat at any other table they prefer. On three or four occasions the whole of the seats in the room, which are 302 in number, have been occupied at once; and when the immense population of London, the ease of obtaining admission to read, and the value of the privilege are considered, no surprise will be felt at the circumstance. Those who obtain admission have at their command, arranged on the walls around them, a select library of 20,000 volumes, comprising books of reference of all kinds. They may at pleasure, by merely writing for what they want, obtain as many volumes as they please of a printed and manuscript library of more than 600,000 volumes, beyond all comparison the finest in England, and probably at this moment the completest for use in Europe. Their ample seats in a magnificent room are furnished with every accommodation for writing and reading, and they are met on all sides with civility and attention. Some improvements may yet be required, but such advantages as those now accessible without fee or reward, were inaccessible on any terms to a former generation; and even now, a nobleman in his private library may often miss facilities to be found in the reading-room of the Museum.

The following are the most important directions respecting it, taken from a printed paper which is delivered to every reader.

"The reading-room of the Museum is open every day, except Sundays, Ash Wednesday, Good Friday, Christmas Day, and any Fast or Thanksgiving days appointed by authority; except also from the 1st to the 7th of January, the 1st to the 7th of May, and the 1st to the 7th of September, inclusive.

"The hours are from nine till four in the months of November, December, January, and February; from nine till five in the months of September, October, March, and April; and from nine till six in the months of May, June, July, and August.

"Any person desiring to be admitted into the reading-room is to apply *in writing*,—addressed "To the Principal Librarian of the British Museum," and not otherwise,—specifying his description and place of abode, and accompanying his letter *with a written recommendation*, satisfactory to an officer of the Museum; and thereupon, the principal librarian may grant him admission for a term not exceeding six months, or refer the application to the trustees at their next meeting. Any reader, once admitted, may apply at the close of his term for the renewal of his ticket, without a fresh recommendation, but producing his last ticket of admission.

"The tickets of admission given to readers are not transferable, and each person must, if required, produce his ticket.

"Persons under eighteen years of age are not admissible.

"Readers, before leaving the room, are to return the books, manuscripts, or maps which they have received to an attendant, and are to obtain the corresponding ticket; *the reader being responsible for such books, manuscripts, or maps so long as the ticket remains uncanceled.*

"It may be sufficient merely to suggest, that *silence* is absolutely requisite in a place dedicated to the purposes of study."

Department of Manuscripts.—The history of the Manuscript department is in its general outline similar to that of the Printed Books, though its development has of course not been so immense. It was formed at the outset by the union of four great collections; other whole collections were afterwards added from time to time by purchase; and more recently a liberal expenditure has taken place in making selections at sales, both English and foreign. The Harleian, Sloanean, and Cottonian manuscripts formed the nucleus of the department, followed, in 1757, by the manuscripts of the ancient royal library of England. This last collection, of about 1950 volumes, contains whatever had been brought together by our kings, from King Richard II. to King George II. Many of these manuscripts came into the royal collection at the time when our monastic institutions were destroyed, and some still retain the anathemas upon their spare leaves which the donors denounced against those who should alienate the respective volumes from the places of their original deposit. Old scholastic divinity abounds in this collection; but it possesses also about fifty volumes of Chronicles, some of which appear to have been executed for King Edward IV., and a volume of romances presented by Talbot, earl of Shrewsbury (Shakespeare's Talbot), to Margaret of Anjou. The great ornament of the collection, however, is the 'Codex Alexandrinus,' an ancient Greek copy of the Scriptures, supposed to have been executed by Thecla, a lady of Alexandria, in the 4th or 6th century, and presented by Cyril Lucar, the patriarch of Constantinople, to King Charles I. It is generally acknowledged by critics to be one of the two most ancient copies of the Scriptures in existence, and an elaborate edition of the New Testament portion of it was executed by Dr. Woide, and of the Old Testament portion, at the public expense, by the Rev. H. H. Baber, from 1822 to 1837 keeper of the Printed Books. It has also many volumes, enriched by the finest illuminators of different countries, in a succession of periods to the 16th century; a numerous assemblage of the domestic music-books of Henry VIII.; and the Basilicon Doron of King James I., in his own hand-writing.

The Cottonian collection originally consisted of 958 volumes, which were supposed to be reduced to 746, exclusive of some fragments, by an unfortunate fire which injured it in 1731, when it was deposited at

Ashburnham House in Westminster. Some of the injured volumes however were partially restored at the commencement of the present century; and since 1845 many have been recovered with singular skill by Mr. Gough, who has been employed for the purpose. The collection is rich in books that formerly belonged to monastic libraries, and in state papers of the most interesting description, coming down to the time of the collector, Sir Robert Cotton, who was born in 1570 and died in 1631. It abounds in Anglo-Saxon manuscripts, one of which is the invaluable 'Durham Book,'—a copy of the Gospels written between the years 698 and 720, and interlined with a translation in Northumbrian Saxon, which belonged to the cathedral of Durham, and was supposed to have been by miracle preserved from destruction by the heathen Danes. A facsimile of some of its beautiful illuminations is given in Sir Frederick Madden's 'Illuminated Ornaments reduced from MSS. and early printed Books, from the 6th to the 17th centuries,' in which Sir Frederick, the present keeper of the department, gives the history of many of the treasures under his charge. Another interesting Saxon book is a copy of the Gospels supposed to have been used to administer the oath at the coronation of the Saxon king Athelstan, and which was certainly used for that purpose at the coronation of King Charles I. More than 200 volumes of the Cottonian collection consist of the letters of kings and statesmen, and have supplied some of the most interesting matter for Sir Henry Ellis's three collections of 'Letters Illustrative of English History.' Among its treasures is one of the original copies of 'Magna Charta,' unfortunately much damaged by the fire at Ashburnham House, respecting which the story is told that Sir Robert Cotton accidentally discovered it in the hands of a tailor, who was going to cut it up for a measure.

The Harleian collection, which was purchased for 10,000*l.* only, consists of 7639 volumes, exclusive of 14,000 original rolls, charters, deeds, and other legal instruments. Its contents are as miscellaneous as they are valuable; they embrace all languages, from English and Latin to Slavonic and Chinese, including "poems, essays, ditties, ancient ballads, plays, and other poetical pieces, in almost every modern language," but particularly in French and English. There are a great number of volumes of original and transcribed letters, of service-books of the Romish Church, of Visitations of Counties and other heraldic manuscripts, and there are some valuable manuscripts of classical antiquity,—a very early 'Odyssey,' and two copies of the Latin Gospels in letters of gold.

The Sloane collection, consisting of 4100 volumes, chiefly of the 16th and 17th centuries, comprises a number of alchemical and medical manuscripts, and several on natural history, including some fine drawings of insects by Madame Merian. Its most valuable materials are volumes of voyages and travels, in particular the papers of Kämpfer, the first scientific describer of Japan, the original manuscript of whose work is among them, and the scientific correspondence of Sir Hans Sloane, and others. The Lansdowne manuscripts, 1245 volumes, bought in 1805 for 4925*l.* of the heirs of the first Marquis of Lansdowne, better known as the Earl of Shelburne in his career as a statesman, chiefly consists of materials for English history and topography, including some chronicles and letters of value. The Hargrave collection of 500 manuscripts was in 1813 bought with the rest of the possessor's library for 8000*l.* during his lifetime, and relates entirely to law, the most noticeable object being an 'Abridgment of Equity,' in 45 volumes, by a Master of the Rolls. The Burney collection of about 520 volumes, bought with the printed book library of the same owner, and valued separately at about 4500*l.*, is distinguished for its classical manuscripts, eighty of which are in Greek, and among them a fine Ptolemy's Geography of the 15th century, and a celebrated copy of the Iliad, formerly belonging to Mr. Charles Townley, of a date not later than the end of the 13th century, and which was separately valued at 600 guineas. The presentation of the library of George III. brought with it about 440 volumes of manuscript, one of them the album of King Charles I., with the autographs of all the most distinguished personages of his court; another the original manuscript of Dr. Johnson's tragedy of Irene, and another some autograph correspondence of Dr. Franklin. At the death, in 1829, of Francis Henry Egerton, the eighth Earl of Bridgewater, he bequeathed to the Museum not only a collection of 67 manuscripts, chiefly relating to French and Italian history and literature, but the sums of 5000*l.* and 7000*l.*, the interest of the former to be employed in purchasing additions to the Egerton collection, and of the latter to paying the salary of an Egerton librarian. In 1838, Lord Farnborough, a trustee, left at his decease a sum of more than 80*l.* a year as an addition to the Bridgewater bequest. There is therefore an annual augmentation of the Egerton collection at the Museum by means of manuscripts specially purchased from this united fund. In 1831 and 1835, the Museum, by agreement with the Royal Society, acquired what is called the Arundel collection of manuscripts, which had been brought together by the Earl of Arundel, afterwards Earl of Norfolk, who died in 1646. The collection was presented to the Royal Society in 1681, by Mr. Henry Howard. It consists of 600 volumes, and contains a large assemblage of books of jurisprudence, forming what was probably considered in the middle of the 15th century, a complete library of civil and canon law, but it has also abundant materials for the history of our own country and language, including among several early chronicles no less than seven copies of Geoffrey of Monmouth. Books

of early English poetry, and manuscripts illustrating the language of France in the 12th and three succeeding centuries, also add to its value. In 1841, the Museum purchased in a mass the manuscript collection of Dr. Butler, bishop of Lichfield and Coventry, consisting of biblical manuscripts, copies of classical writers, and a collection of autographs.

These are the main separate collections of manuscripts. Of the collections which may be said to have merged in the general one, some of the most important on historical and topographical subjects are Rymer's partly unused materials for his 'Fœdera,' in 58 volumes, and Madox's for his 'History of the Exchequer,' in 94; Lyson's for his 'Environs of London,' and 'Magna Britannia,' in 64; Archdeacon Coxe's for his different historical works in 206; Dr. Birch's valuable historical and biographical transcripts, in 378; Cole's collections for a history of Cambridge, of Cambridge University, and Cambridgeshire, in 92; Hasted's collections for Kent, in 62; Sir William Burrell's and the Rev. William Hayley's joint collections for a history of Sussex in 41; Wolley's for Derbyshire in 53; Jermyn's for Suffolk, in 51; Davy's for Suffolk in 160. The diplomatic correspondence of Sir Andrew Mitchell, known as the ambassador to Frederick the Great, in 69 volumes, and that of Count Joseph de la Puisaye, an active adherent of the Bourbons, during the French revolution, in 117 volumes; the papers and correspondence of the Marquis Wellesley, during his administration of India, in 1351 volumes; and the papers of Sir Hudson Lowe during Napoleon's captivity at St. Helena, supply materials for history which have been already partly made use of. A miscellaneous collection, bequeathed by Sir Joseph Banks, contains, among other nautical journals, the log-book of Tasman, the discoverer of Van Diemen's Land, now named after him Tasmania. A collection of manuscripts on the affairs of Italy, in 604 volumes, purchased in 1830, at the sale of the Earl of Guildford's library, was followed in 1836 by 85 volumes of 'Relazioni' or reports to the Signory of Venice from their ambassadors, and in 1837 by 291 volumes of selections from the Canonici collection of Italian literature. In 1844 the Museum received by donation 96 volumes of Welsh manuscripts, from the Welsh school, and 128 from the Cymmrodorion Society, comprising the whole collections of both establishments, which had up to that period been almost inaccessible, because from their paucity it had been out of the question to pay a librarian to attend to them. They consist chiefly of transcripts made for the use of the editors of the 'Myvyrian Archæology.'

Of Oriental manuscripts, the Museum was enriched with two collections in the year 1825—one of 802 volumes of Syriac, Arabic, Persian, and Turkish, collected by Claudius Rich, the English consul at Bagdad, and described by him in the periodical called the 'Mines de l'Orient,' and another of 136 volumes, bequeathed by John Fowler Hull, a young Orientalist of fortune, who also bequeathed a collection of Chinese and Oriental printed books. In 1841 a collection was purchased of 49 volumes of ancient Syriac manuscripts, obtained by the Rev. Henry Tattam, from the monastery of St. Mary Deipara, in the desert of Nitria, about 70 miles from Cairo; and in 1843 another collection, obtained by the same gentleman from the same place, of 317 volumes. In 1847, a third collection of 173 manuscripts from the same library in the desert, was purchased of M. Pachon, a Frenchman. The curious history of the acquisition of these collections is given in some detail in an article in the 77th volume of the 'Quarterly Review.' When the second collection arrived at the Museum, very few of the volumes were perfect; nearly 200 had been torn up, it is said, into separate leaves, and then mingled apparently at random. The Rev. William Cureton, then assistant-keeper of the manuscripts, in the course of eighteen months disentangled the confusion, and has been fortunate enough to make three discoveries which he has published—of a copy of the Epistles of St. Ignatius, of palimpsest a portion of the Iliad, and of the Gospel of St. Matthew, in Syriac, by some supposed to be the language in which it was originally written. The volumes are found to consist, in the first two collections only, of upwards of 1000 different manuscripts, or portions of manuscripts, ranging from the year 411 to the year 1292. An augmentation of 236 oriental manuscripts was made in 1833, by a purchase from Mr. Rich, the American bookseller, of a collection formed by an American consul, and 245 Persian manuscripts were presented in 1847 by the sons of Major-General Yule. The result was, that in 1854 the number of manuscript volumes of Arabic was 1060; of Hebrew, 232; of Persian, 1082; of Sanskrit, 122; of Syriac, 631; of Turkish, 268; with small collections of different sizes, the lowest in number 12, and highest 83, of Ethiopic, Armenian, Burmese, Bugis, Cingalese, Hindustani, Javanese, Malay, Malayalma, Pali, Siamese, Tamul, and Telugu. A table of their numbers will be found in the 'Handbook to the Library of the British Museum,' by Richard Sims, of the department of manuscripts, a valuable little volume, which contains a variety of useful information with regard to the manuscripts, and to which we have been largely indebted.

A foreign authority, Dr. Pertz, librarian of the Royal Library at Berlin, has stated of the British Museum (in his 'Archiv für Geschichtskunde,' vol. ix), that "the number of manuscripts acquired since 1827 is very great; the establishment obtains information of every important sale on the continent, and it is easy to perceive that if affairs continue in their present course, every important manuscript in

Europe, that is not already locked up in fiscal collections or does not become so, will in the course of another century become the property of the British Museum." On the other hand, complaints have been frequently made in England that owing to the paucity of public grants, manuscripts which there was an opportunity of acquiring with a liberal expenditure, have been allowed to pass into private hands, where they are inaccessible except by private favour; and have been and often are locked up in "cold obstruction" by private caprice. The date assigned by Dr. Pertz for this new impulse is that of the appointment of the Rev. Josiah Forshall to the keepership of the manuscripts, and there can be no doubt of the increased activity of the department in the way of acquisition during his administration (1827-1837), and that of his successor Sir Frederic Madden. Some results of this activity have been already enumerated in the mention of the separate collections, others are brought to the cognisance of the public in the exhibition cases of the manuscript department, since that exhibition commenced in 1858. In these cases, the 'Magna Charta,' the 'Alexandrian Codex,' the 'Durham Book,' and many of the other curiosities already mentioned, are laid open to public curiosity; and also a selection of autographs. There are those of English sovereigns from Richard II. to George III.; of several foreign sovereigns, including Charles V., the Czar Peter, Frederick the Great, and Napoleon; others of statesmen and warriors, including the last letter of Nelson on the eve of the battle of Trafalgar, and a calculation made by Wellington on the field of Waterloo; others of men of genius and world-wide influence, including Ariosto and Tasso, Luther and Calvin, Erasmus and Voltaire. There are also the original manuscripts of Tasso's *Malpiglio*, of some of Lope de Vega's plays, of Ben Jonson's *Masque of Queens*, of Pope's translation of Homer, of Sterne's *Sentimental Journey*, of Johnson's *Irene*, and of Walter Scott's *Kenilworth*, in the handwriting of their authors. There is the deed by which Milton assigned the copyright of 'Paradise Lost,' presented by Rogers, the poet, in 1852; and there is a mortgage deed with the signature of Shakspeare, purchased in 1858. The mortgage is for 60*l.*; the signature, we believe, was purchased for 320*l.*

Department of Antiquities.—In the infancy of the Museum, the antiquities being few in number and of little value, were considered, with other artificial curiosities, as an appendage to the natural history; the coins, medals, and drawings of the Museum collection were at that time appended to the department of manuscripts; and the prints and engravings to the library of printed books. When, in 1772, a very considerable assemblage of articles of Greek and Roman antiquity, comprising the largest collection then known of ancient fictile vases, was purchased of Sir William Hamilton for 8400*l.*, the augmentations were not so numerous as to require an increase of the establishment. The arrival of the Egyptian monuments acquired by the capitulation of Alexandria, in 1801, which were ordered in the following year by King George III. to be placed in the British Museum, first suggested the erection of an additional edifice, rendered still more indispensable by the purchase of the Townley Marbles in 1805. Accordingly, upon the completion of the building intended for the two collections, a new department was created, in 1807, by the name of the Department of Antiquities, and the magnificent collection of ancient sculpture was at length opened for the inspection of strangers and the improvement of artists, an advantage which the students of the Fine Arts had never before enjoyed in this country. To this department the Hamilton vases and antiquities were transferred, together with the coins, medals, drawings, and engravings.

In 1814, a communication having been made by the Townley family that there still remained in their possession a very large collection of ancient bronze figures and utensils, of Greek and Roman coins, gems, drawings, &c., all of which might serve essentially to illustrate the sculptures purchased in 1805, the House of Commons granted in that year the sum of 8200*l.* for the purchase.

In 1815 the Prince Regent, at an expense of little less than 20,000*l.*, purchased and ordered to be deposited in the Museum an extensive series of sculptures, the frieze of the temple of Apollo Epicurius, at Phigaleia in Arcadia, which are known from Pausanias to be the genuine productions of the earlier time of the school of Phidias. To these, in 1816, was added the Elgin collection, which as contributing to the progress of the arts in this country, is the most important accession received by the Museum since its institution. It chiefly consists of the exquisite sculptures which once adorned the pediments and frieze of the Temple of Minerva, on the Acropolis of Athens. For the purchase of these, parliament voted the sum of 35,000*l.*

Since this period, many individual objects of much interest have been, from time to time, added to these collections: as, for example, a Cupid, from Mr. Burke's collection; a group of Mithras, bought of Mr. Standish; the Rondinini Faun; a Torso of Venus, which was injured by the fire at Richmond House; a statue of Hadrian; a bas-relief of the Apotheosis of Homer, purchased for 1000*l.*; a Venus of the Capitol, presented by King William IV.; while, in later years, the following great collections have been secured for the Museum, chiefly by the zeal and labour of English travellers.

I. The *Lycian Marbles*, procured during two expeditions in the years 1842-44 by Sir Charles Fellows, and consisting chiefly of reliefs from an Ionic edifice, and from the so-called Harpy Tomb, at Xanthus; together with a miscellaneous assortment of sculptures, some native

Lycian, but mostly Asiatic Greek, from different places at the S.W. angle of Asia Minor.

II. *Sculptures from the Mausoleum of Halicarnassus*, comprising eleven bas-reliefs, with combats of Greeks and Amazons; procured for the Museum through Sir Stratford Canning, at that time H. M. Ambassador at Constantinople.

III. *Sculptures from Nineveh*, obtained by a series of excavations conducted during 1847-50 by A. H. Layard, Esq.; and, on his return to Europe, between the years 1851-56, by H. Rassam, Esq., and W. K. Loftus, Esq. A collection comprising the results of very extensive excavations at Nimrud (the Calah of the Bible), Koyunjik (Nineveh), Kalah Sherghat (Assur); together with a large assortment of miscellaneous antiquities from Babylon, Birs-i-Nimrud (Borsippa), and from many ancient sites in Southern Chaldaea, including those of Warka (Erech), and of Mugaher (Ur of the Chaldees). To exhibit these monuments in some degree, a suite of three long narrow rooms, originally intended for other purposes, exceeding 300 feet in length, has been made use of, with an additional transept at their southern end, together with a large room in the basement of the building. In these rooms the sculptures have been arranged, so far as has been possible, chronologically; an arrangement, however, which is far from complete, owing to the contracted nature of the space devoted to these monuments. With these may be noted a collection of Persepolitan marbles, presented in 1825 by Sir Gore Ouseley, forming a valuable addition to some which had been previously presented by the Earl of Aberdeen.

IV. A much larger collection of sculptures and other antiquities, excavated by C. T. Newton, Esq., H.M. vice-consul at Mytilene, on the site of the *Mausoleum of Halicarnassus*, during the years 1856-58, and comprising many additional slabs from the frieze, two colossal statues (probably those of King Mausolus and of his Queen Artemisia); together with portions of two colossal horses, and of the quadriga which surmounted the edifice; with columns, capitals, and other architectural members in sufficient number and perfection to render it possible for any well-informed architect to reconstruct the original building.

V. A curious collection (also procured by C. T. Newton, Esq., during the years 1857-58) from the site of the Temple of Apollo at Didymi, near Miletus, and from Cnidus, embracing several sitting figures of the earliest Greek art, which were originally placed in the *Sacred Way* leading up to the Temple of Apollo from the sea; together with an inscribed lion, and other inscriptions in the Archaic Greek character. From Cnidus, Mr. Newton has sent home a magnificent colossal lion, with many other interesting fragments of sculpture.

VI. A large number of mosaic pavements, and nearly 100 Phœnician inscriptions, excavated on the site of ancient Carthage, by the Rev. Nathan Davis, in the years 1856-59. The pavements, many of which are in excellent preservation, are unquestionably Roman, and perhaps not earlier than the 2nd or 3rd century A.D. Many however of the Phœnician inscriptions may fairly be presumed to have belonged to the ancient Carthaginian people, before the destruction of Carthage by Scipio. For the appropriate exhibition of these large and important collections, no provision can be made within the limits of the present building. It has been therefore found necessary to place Mr. Newton's sculptures for the present in a glass shed erected under the columns in the portico, while Mr. Davis's Carthaginian antiquities may be found in an unoccupied part of the basement, to the right of the new Nineveh Room.

Coins and Medals.—The foundation of this part of the collection was laid in the cabinets of Sir Robert Cotton and Sir Hans Sloane. More than 6000 ancient medals were purchased with the Hamilton collection in 1772. In 1799, a collection of coins and medals, estimated at the value of 6000*l.*, was bequeathed to the Museum by the Rev. Clayton Mordaunt Cracherode. In 1802 the trustees purchased the most complete series of Anglo-Saxon coins then known, which had belonged to Samuel Tyssen, Esq., for 620*l.* In 1810 a series of the coins of England from the Conquest to the reign of George III., which had been made by Edward Roberts, Esq., of the Exchequer, for his son, was purchased for the sum of 4000 guineas; and about the same time a series of papal medals for 135*l.*, and a collection of Greek coins from Col. de Bosset for 800*l.* In 1814 the Townley collection of Greek and Roman coins (particularly rich in Roman large and second brass) was added by vote of parliament, and a collection of Greek coins offered for sale by Capt. Cust, was purchased by the Treasury for the sum of 630*l.* Another considerable as well as choice collection of Greek coins was obtained at the time of the purchase of the Elgin marbles. In 1818 Lady Banks presented all such coins and medals belonging to the extensive cabinet of Mrs. S. S. Banks as were not previously in the Museum, including a considerable collection of foreign coins. In 1824 Mr. R. Payne Knight bequeathed his Greek coins to the Museum, which, joined to the Greek coins already in the cabinets, made the Museum series of kings and cities superior even to the celebrated collection of the King of France. In the following year King George IV. presented to the Museum a cabinet of coins and medals which had been attached to the library of George III., which contained a valuable assortment of German coins, and of the medals of the illustrious men of Italy. During more recent days vast additions have been made to the collection of Greek and Roman coins by purchases at several important sales, such as those of the Duke of Devonshire,

Messrs. Trattle, Borrell, Thomas, Boyne, Campana, Rollin, Durrant, Cuff, &c., or from individual collectors, such as Messrs. Burgon, E. Thomas, &c., by means of which the ancient collections in the Museum have been placed on an equality with those of any European cabinet. Much, too, has also been added by the generosity of individuals, especially in the case of coins belonging to England; thus, 174 coins of the Anglo-Saxon series, found at Dorking in Surrey in 1818, were presented by Robert Barclay, Esq., of Bury Hill, and George Dewdney, Esq., of Dorking; a large collection of the coins of the first two Edwards, found at Tutbury in Staffordshire, in June, 1831, by Lord Holland, chancellor of the duchy of Lancaster, together with the produce of a find at Cuerdale in Lancashire, in May, 1840, consisting of ingots of silver armillæ, &c., weighing nearly 1000 oz., and between 6000 or 7000 coins (the most important of which were presented to the Museum by the Chancellor of the Duchy of Lancaster). The English collection of coins has also been enriched simultaneously with the classical, by large purchases, often from the same sales, and also by accidental purchases, such as that of a selection from 5700 pennies found at Tealby in Lincolnshire in 1814; 296 coins of the Styca series, found at Hexham in 1832; and 659 varieties of the money of William the Conqueror, discovered at Beaworth in Hampshire. The result has been that, in coins relating to Great Britain, the collection in the British Museum is, as it should be, unrivalled.

The Oriental collection of coins, now extending to 16,000 or 17,000 pieces, is of the most recent growth. Originally founded in a few specimens procured by Sir Hans Sloane, it remained unincreased till 1825, when a large assemblage of Mohammedan and other coins were purchased by Parliament for 1000*l.* of C. J. Rich, Esq. This collection was greatly augmented by the magnificent bequest of his cabinet of Oriental coins by William Marsden, Esq., in 1834. This beautiful collection, the whole of which had been arranged and described by its owner, consisted of nearly 3500 specimens, one-fifth of which were in gold. Since then, large accessions have come to this series; by the purchase of the cabinets of the late James Prinsep, Esq. (comprehending many of the earliest discovered Bactrian coins); by those of Edward Thomas, Esq., H.E.I.C.S., and Major Cunningham; and by extensive purchases at the sales of Messrs. Pietraszewski, Bird, &c.

The whole of these collections—the Ancient, Mediæval, Modern, and Oriental—are now preserved in one room called the Medal Room; no space having been as yet found in which any of the coins can be exhibited to the public.

In a room behind the Medal room are preserved an admirable assemblage of engraved gems, chiefly procured by Sir W. Hamilton, the Rev. C. M. Cracherode, and Charles Townley, Esq.; the Portland Vase, lent for exhibition by the Duke of Portland; together with a collection of gold ornaments, rings, &c., from the tombs of Ancient Etruria, from Wales, from the bogs of Ireland, &c. Here also are now exhibited some miscellaneous objects formerly kept in the Medal room, as the snuff-box of Napoleon the Great, presented by him to Lady Holland; another, bearing his portrait, given by him to the Hon. Mrs. Damer; a watch, said to have been that of Oliver Cromwell; a gold inlaid ring, bearing the name of Ethelwulf Rex; and a gold breastplate, found at Mold, in Flintshire, probably once the property of a British or Celtic chieftain.

The Egyptian Collections, which are now arranged in one large saloon on the ground floor, and in two smaller rooms up-stairs, is mainly founded upon the great monuments of that country, collected by the French savans during the occupation of Egypt by the army of Napoleon, and ceded to England at the capitulation of Alexandria in 1801. From this time no material additions were made to this part of the department of antiquities; but in 1817 the upper part of a fine colossal statue, commonly though incorrectly called the Memnon, taken from Thebes by Belzoni, was given to the Museum in the joint names of Henry Salt, Esq., the British consul at Alexandria, and Louis Burckhardt, Esq. In 1823 the trustees, by the aid of parliament, obtained Mr. Salt's first collection of Egyptian antiquities (exclusive of an alabaster sarcophagus, afterwards purchased by Sir John Soane) for 2000*l.* Another collection, particularly illustrative of the domestic manners of the ancient inhabitants of Egypt, belonging to Mr. Joseph Sams, was purchased by parliament in 1834, for 2500*l.*: a considerable number of antiquities of the same description were presented to the Museum in the same year by J. G. Wilkinson, Esq., and in 1835 a still larger accession was obtained by an expenditure of 5081*l.* 16*s.*, at the sale of Mr. Salt's third collection of antiquities, including numerous papyri which have been since unrolled. In this year also Lord Prudhoe presented to the Museum the two fine lions of red granite which his lordship had procured at Jebel Barkal in Nubia. From that time to the present day, no year has passed without considerable additions being made to the Egyptian collection; these have, however, been for the most part objects small in size, such as scarabæi, gems, bronzes, and vitreous ornaments, together with many papyri, in which ancient writings the Museum is now very rich.

Besides the Egyptian, Assyrian, and Classical monuments already noticed, two rooms on the upper story are now appropriated to the Græco-Italian vases, a class of which the Museum possesses the most valuable and interesting assemblage in the world, with the exception of that in the Museo Borbonico at Naples. A portion of another room has been devoted to the exhibition of a noble collection of miscel-

laneous antiquities, formed by the late Hon. Sir William Temple, during twenty years in which he held the office of H.M. minister at the court of Naples, and munificently bequeathed by him to his country at his death in 1856. A third room contains a very valuable collection of bronze statuettes, vases, ornaments, articles of domestic use, candelabra, helmets, &c., founded originally on those which had belonged to Sir W. Hamilton and Mr. Townley, but largely increased in 1824 by Mr. Payne Knight's bequest of his bronzes, 798 in number,—the finest collection which has ever been brought together by one man. In this room also are preserved the bronzes of Siris, so called because stated to have been found in 1820 near the river of that name, which were purchased in 1833 by subscription for 1000*l.* of the Chev. Bröndsted. Since this period many excellent individual specimens have been placed in this room, and especially the contents of a very ancient Etruscan tomb, from the necropolis of Vulci, known as "La Polledrara;" and an attempt has been made to arrange the various objects in it according to the principles so admirably laid down in C. O. Müller's 'Hand-book of Ancient Art.' A fourth room, called the British and Mediæval room, adjoining the bronze room, contains a large and miscellaneous collection of objects, comprising,—1. British antiquities anterior to the Romans, flint knives, arrow heads, stone hammers, bronze implements, swords, shields, spears, daggers, &c.; Roman antiquities, glass and earthenware vessels from tombs, pottery, Samian and Arretine ware, roof and flue tiles. With these are arranged the bulk of Mr. Roach Smith's collections, as peculiarly illustrative of Roman London. 2. Anglo-Saxon antiquities, weapons, urns, &c., from ancient cemeteries. 3. The Mediæval collection, comprising metal work, paintings from St. Stephen's chapel, Westminster; ivory carvings of great beauty from the 14th to 17th centuries; enamels, English pottery, German and Venetian glass, and a rich collection of Majolica, many fine specimens of which were procured at the sale of Mr. Bernal's collection, and Flemish stoneware.

Print Room.—In the Department which contains drawings and engravings there are one or two superb drawings by Rubens; a large collection of drawings of the Italian school; three volumes, a part of Mr. R. P. Knight's bequest, containing 272 original drawings of Claude Lorraine; a numerous assemblage of drawings of the Dutch school; several hundred drawings by Albert Durer and other old German masters; a large collection of Van Huysum's drawings of plants, which formerly belonged to the Sloane collection; a collection of drawings of plants and costumes by native artists of China; Parr's and Revett's views in Greece and Asia Minor, chiefly architectural, in two volumes, accompanied by a third volume, containing Towne's views in Rome and its vicinity; three volumes of highly-finished drawings in black chalk, copied from the most celebrated pictures in Rome, and accompanied by an extra volume after the frescoes of Guido in the private chapel of the Vatican, by Mosman; these were presented to the Museum by the Earl of Exeter, and cost nearly 3000*l.* There is also a large collection of drawings from antique marbles, gems, &c., formerly belonging to Mr. Charles Townley; and there are two folios of drawings made under the direction of the Earl of Elgin at Athens.

In the collection of prints, among numerous impressions of the works of Niello, is a sulphur of the celebrated Pax by Maso Finiguerra, of the Assumption of the Virgin, anno 1452, purchased in 1835 for 270 guineas. The prints of the different masters are for the most part arranged in schools, as the Florentine school, the school of Siena, the Roman school, the Bolognese, Lombard, and Venetian schools, the schools of Genoa and Naples, the French school, &c. There are large and almost complete collections of the works of Marc Antonio, Benasconi, Rembrandt, and Hollar; a very fine and extensive assemblage of Hogarth's prints, the foundation of which was laid in 1823 by the purchase of Mr. Packer's collection, of Dunmow, for 315*l.*; a Granger collection of English portraits of great extent; a very large collection of early German prints in wood; an almost perfect collection of prints engraved after the pictures of Sir Joshua Reynolds; a large collection of Bartolozzi's engravings; Dr. Burney's collection of theatrical portraits; an immense collection of foreign portraits, purchased with the library of the Baron von Moll, of Munich; and a Pennant's 'History of London,' illustrated with prints and drawings, in fourteen volumes in folio of the largest size, made by the late Mr. Cole at an expense of 7000*l.*, by whom it was bequeathed to the Museum.

In the print room also is preserved one of the most wonderful specimens of art, in a carving in stone by Albert Durer, in alto-rilievo, representing the birth of St. John the Baptist, dated 1510, for which Mr. Knight, who bequeathed it to the Museum, gave 500*l.*

In 1836 this department was considerably enriched by the purchase of the Sheepshanks collection of Dutch etchings for the sum of 5000*l.* It was described by the then keeper of the department, Mr. Josi, in his evidence before the select committee of the House of Commons in the same year, as more perfect than any similar collection existing at Vienna, or at Paris or Amsterdam. The entire collection embraces as many as 8450 engravings and drawings, bound in thirty-two volumes. The sum annually allowed at that time for the purchase of prints and drawings amounted only to about 250*l.*, which has since been increased to 1200*l.* or 1500*l.*, and has occasionally even reached as high as 2000*l.* This is exclusive of any special grants for extraordinary purchases, like that of the Sheepshanks collection.

The more recent acquisitions of importance in this department are:

a collection of engravings by Cornelius and Jan Visscher, in 1840; a collection of 209 portraits, published by Messrs. Paul and Dominic Colnaghi, who presented them to the Museum, in 1842; "a most valuable purchase," made in the same year, "out of the collection late the property of Mr. Harding, consisting of the finest specimens of the works of the early Italian and German masters, etchings by Rembrandt, many of them in a unique state, and some splendid specimens of engravings by Wille, Woollett, Muller, Langhi, Bewick, &c., comprising 321 pieces." These were purchased for the sum of 2390*l*. In 1843 a collection of Raphael Morghens was acquired for 1575*l*.; and in 1845 a collection of early German engravings was obtained for 2830*l*., and of Italian for 4875*l*. These are described in the Parliamentary return as follows:—"A curious collection of the prints of the earlier German engravers, amounting to 1755 in number; amongst them will be found no fewer than 164 specimens by the Master of 1466 and the artists of that period;" and "An uncommonly fine collection of early Italian art, embracing the most extensive collection of the workers in nielli known. It consists of 103 specimens in silver, 15 impressions in sulphur, and 63 impressions on paper. In 1848 there was added another large collection of etchings and drawings, purchased from the Messrs. Smith for 4200*l*. In 1851, a collection of caricatures by Gillray, 1398 in number, was presented by W. Smith, Esq.; and in 1853, a collection of original drawings made by Sir Wm. Gell, amounting in number to 800, was bequeathed by the late Hon. R. Keppel Craven.

In the report of the Royal Commissioners of Inquiry into the British Museum, a recommendation was given to exhibit some of the engravings to the public. In compliance with this recommendation, a selection from the prints and drawings is now exhibited in the King's Library, the arrangement of which is as follows:—

"Four screens have been fixed on each side; those on the left hand (when entering from the Manuscript department) being appropriated to the exhibition of drawings; those on the right to the display of engravings. The space available for the exhibition of these objects being necessarily circumscribed, the purpose has been to offer such a selection as shall give to the public an opportunity of tracing the development of design as shown in the sketches and studies of the great masters of Italy, Germany, Flanders, and Holland, during the 15th, 16th, and 17th centuries. Screens I. and II. are devoted to the schools of Italy; III. and IV. to those of Germany, Flanders, and Holland. With respect to the engravings, it will be seen that the arrangement is such as will afford the opportunity of comparing the contemporaneous productions of the principal masters of the schools of Italy, Germany, Flanders, and Holland, from the middle of the 15th to the end of the 16th century. These are followed by a selection of a few of the most successful efforts of the Dutch and Flemish engravers of the 17th century, with specimens of etchings by their most distinguished painters, who so enthusiastically and so successfully practised that branch of art at the same period. Some fine examples by the Italian workers in niello, consisting of engraved silver plates, sulphur casts, and impressions on paper, are shown in the glazed cases marked I. and II., and in III. and IV. are early Italian and German wood blocks, printed in chiaroscuro."

Among the drawings thus exhibited will be found admirable specimens of Giotto, Fra Angelico, Masaccio, Filippo Lippi and Filippino Lippi, Paolo Uccelli, Sandro Botticelli, Michel Angelo, Lorenzo Credi, Fra Bartolommeo, and Andrea Del Sarto, all of the Florentine School; of Perugino, Raffaele, Giulio Romano, Muziano, and others of the Roman School; of Giovanni and Gentile Bellini, Giorgione, Campagnola, Tiziano, Paolo Veronese, Tintoretto, Bassano, and Canaletto of the Venetian School; of Leonardo da Vinci, and Gaudenzio Ferrari, of the Milanese School; of Correggio and Parmigiano, of the Parmesan School; and of Francia, the three Carracci, Guido, and Guercino, of the Bolognese School. Among the drawings of the German masters are placed some fine examples of Michael Wohlgemuth, Schongauer, Peter Vischer, Albert Durer, Hans Holbein, Grun, Burgkmair, Altdorfer, and Rottenhamer. The Flemish and Dutch artists are well represented in a collection of drawings by Vander Weyde, Hans Memling, Mabuse, Heemskerck, Breughel, Bril, Rubens, Van Dyck, Snyder, Rembrandt, Bol, Ruysdael, Ostade, Van de Velde, Bakhuyzen, Berghem, Paul Potter, and Cuyp. While this collection of drawings, as a whole, illustrates the history of art, many of the specimens that it contains are in themselves highly beautiful, both for design and execution.

The collection of nielli and of sulphur casts in the British Museum is well known to be the finest in the world. Some fine specimens of Maso Finiguerra, the most renowned worker in this branch of art, the parent of engraving, will be found in this exhibition; together with some impressions on paper from works in niello by Finiguerra, Peregrino da Cesena, Francia, and others.

Among the engravings there are several examples of the Italian School, commencing with Baccio Baldini, and including Botticelli, Campagnola, Mantegna, Pollajolo, Leonardo da Vinci, Raimondi, the "Master of the Die," and numerous others. The examples from the German, Flemish, and Dutch schools are still more numerous; embracing

specimens of the "Master of 1466," of Martin Schongauer, Martin Zagel, Albert Durer, Lucas Van Leyden, George Pencz, Goltzius, Muller, Rubens, Van Dyck, Paul Potter, Teniers, Ostade, and Rembrandt. Of the last mentioned there are exhibited some of the finest etchings that the Museum or the world has to show, two of which must be particularly mentioned, namely, No. 212, "Christ healing the Sick: first state, known as the hundred guilder piece, it having sold for that price (equal to about eight guineas,) during the life-time of the painter;" also, No. 217. "Portrait of Ephraim Bonus, an eminent Jewish Physician of Amsterdam: first state, with the black ring, only three other impressions being known."

Departments of Natural History.—Sir Hans Sloane's collection of objects of natural history, which, however insignificant it may now appear, was very considerable for the time when it was brought together, forms the nucleus of the present extensive departments of *Zoology*, *Palaeontology*, *Mineralogy*, and *Botany*. It consisted of quadrupeds and their parts; birds and their parts, eggs, and nests; amphibia, crustacea, shells, echini, entrochi, insects, corals, sponges, zoophytes, stones, ores, bitumens, salts, and an extensive herbarium. But to this department also, in the infancy of the Museum, all miscellaneous artificial curiosities were consigned, with a few antiquities and a collection of anatomical preparations, all of which have since been separated from it.

The science of natural history, however, in course of time, made such rapid progress, that the collection of Sir Hans Sloane, which when purchased was deemed of the first magnitude, declined in its comparative value with respect to every one of its departments.

To supply its deficiencies, the trustees, in 1769, purchased a collection of well-preserved stuffed birds which had been brought over from Holland, for 460*l*. Many additions were afterwards made by purchase and donation. The voyages of discovery early in the reign of George III. brought numerous acquisitions; and in 1816 a rich collection of British zoology, which had belonged to Col. Montague, of Knowle in Devonshire (including a very large number of birds), was purchased for 1100*l*. A valuable collection of stuffed birds was bequeathed to the Museum in 1835, by the late Major General Hardwicke. Since that time still larger acquisitions have been made by presents and purchase, in the class of ornithology, so that the aggregate now forms a collection, not indeed complete, but as extensive as most of the collections in Europe.

Similar progress has been made in increasing the collections of mammalia, fishes, reptiles, insects, and crustacea in the British Museum. With regard to the extent of these collections in 1849, Dr. Gray submitted the following statement to her Majesty's commissioners of inquiry into the constitution and management of the British Museum: "In 1836, Mr. Gray gave some account of the state of the Museum collections, compared with those on the Continent. Since that period he has had the opportunity of again inspecting those collections, and others in the south and eastern parts of Germany, and the south of France, which he had not then seen, and he considers the statements made at that time to require no corrections; but the comparison is now much more favourable for the British Museum, that collection having been increasing very rapidly,—indeed in a most unexampled manner,—while most of the continental collections have for the last six or seven years, for some political reason, been nearly stationary; or, at most, increasing a single part of their collections, or receiving specimens from a single locality where they happened to have a collector staying. To enter into a few details, Mr. Gray believes that the Museum collections of mammalia, birds, shells, and lepidopterous insects, are much more extensive than any other public collection, and superior to all the public collections together. This is certainly the case with the first and last mentioned groups; and he believes also with the other two. The collections of reptiles, fish and crustacea, are only second to those at Paris, if at all below them; but Cuvier, and Valenciennes, and Dumeril, and Bibron, and M. Milne Edwards, having for years been engaged in works on those three classes, they have concentrated their attention on increasing them, and have received specimens from all parts of the world, for the purpose of enabling them to complete their labours, which makes it probable that their collection is richer in these classes. The Museum collection in each of these classes contains many species which the Paris collection wants. The Museum collection of insects, taken as a whole, is much larger and better arranged than that of Paris. In some parts, the Berlin collections exceed it. The collections of corals, sea-eggs, and star-fishes, are very large, far larger than those of all the other European collections together." Since the time when this evidence was submitted to H. M.'s commissioners, the collections in the British Museum have continued to increase both in number and importance.

For this, much is due to the additional stimulus given to the study of natural history through our free intercourse with the public and private museums on the continent, ever since the close of the war in 1815; but a great deal also to the energy and skill of the present keeper of the zoological department, Dr. John Edward Gray, and of his able assistants, Messrs. George Gray, Adam White, Dr. Baird, and Frederick Smith. Dr. Gray succeeded to his present office upon the retirement of the late Mr. Children, in 1840; since which time it is that the Museum collections of zoology have taken the rank that they

* "A Guide to the Drawings and Prints exhibited to the Public in the King's Library."

at present occupy, of being among the first in the world, both for extent and accurate scientific arrangement. To take the department of entomology alone, it will be found that there are at present, at the lowest computation, upwards of a million of specimens, all classified and labelled, in a manner to make them at once available to the student. These have been acquired at different times, and in different ways which it would take long to specify; but it may at least be mentioned that in 1853, the Museum obtained the collection of British insects belonging to the late Mr. James Francis Stephens, one unrivalled in extent, amounting to 88,000 specimens, for the small sum of 400*l*. And since that time it has purchased the collections of Coleoptera, formed by Messrs. Märkel and Braasche, in order to have a *European* collection to compare with the British. The collection of shells in the Museum is very extensive, and would eclipse any yet known, had Dr. Gray's recommendation been complied with by the Treasury, for the purchase of Mr. Cuming's collection, offered to the Museum a few years ago for the sum of 6500*l*. It needs only further to be stated, that the zoological collections generally have been much augmented by specimens obtained from the commanders of the several exploring expeditions, as those of the *Erebus* and *Terror*, *Samarang*, *Rattlesnake*, *Beagle*, &c.

The additions made during the past year (1858), amount to as many as 42,691 specimens, of which there are 6,180 belonging to the class *vertebrata*, 7,812 to the *mollusca* and *radiata*, and 28,699 to the *annulosa*. Of these, a collection of mammalia, birds, reptiles, fish, shells, crustacea, and insects, formed by F. M. Rayner, Esq., Surgeon, R.N., during the voyage of H.M.S. *Herald*, in the *Fiji* group, and other islands of the Pacific, was presented by the Lords of the Admiralty; and a collection of mammalia, birds, reptiles, and their skeletons, as also a series of human skulls from Nepaul, presented by the late resident, B. H. Hodgson, Esq. (See 'Parliamentary Returns, June 1859.')

The method of exhibition to the public, according to the last published 'Guide to the Exhibition Rooms of the British Museum,' is as follows: "The collection of animals is contained in three galleries, and, for the convenience of exhibition, is arranged in two series. The beasts, birds, reptiles, and fishes, are exhibited in the wall cases. The hard parts of the radiated, molluscous, and annulose animals (as shells, corals, sea-eggs, starfish, crustacea), and insects, and the eggs of birds, are arranged in a series in the table cases of the several rooms.

"The names and numbers of the rooms are placed over the doorways in each apartment, and the numbers of the cases over the glass frames.

"The specimens are labelled with the scientific name, the English name when they have one, the country whence they come, and, when they have been presented, with the name of the donor.

"The general collection of mammalia, or beasts which suckle their young, is arranged in three rooms, the hoofed beasts (*ungulata*) being contained in the central saloon and southern zoological gallery, and the beasts with claws (*unguiculata*) in the mammalia saloon."

The insects and crustacea, with the exception of those exhibited in the table-cases in the northern zoological gallery, are for the most part preserved in cabinets in a room on the basement floor, in the north-west angle of the building, and may be seen by persons wishing to consult them for purposes of study, every Tuesday and Thursday on application to the keeper.

The collections of *Palæontology* and *Mineralogy* in the British Museum have also progressed in a ratio quite equal to that of zoology. The first-named of these sciences, which scarcely had an existence when the Museum was founded, is now admirably illustrated by the numerous specimens of organic remains acquired during the last thirty years. Before mentioning these, however, it should be stated that two rather notable acquisitions were made at an early period; namely, of a collection of London clay fossils, from Hampshire, found and described by Solander, and presented to the Museum, in 1766, by Gustavus Brander, Esq., at that time one of the trustees; and the collection, known by the name of the 'Beroldingen Fossils,' acquired by purchase in 1816. In 1839, the collection was much enlarged by the purchase of Dr. Mantell's celebrated museum; and in 1835 and 1840, by those of Mr. Thomas Hawkins, containing some of the finest specimens of ichthyosauri and plesiosauri ever discovered. Numerous other additions have since been made; among which must be specified a remarkable collection of fossil remains of birds discovered in New Zealand by Mr. Walter Mantell, and sold to the Museum by his father.* "These bird remains are referred by Professor Owen to several species, and indeed to distinct genera of birds, some of which are still living in New Zealand, whilst others are, most probably, extinct. Amongst the living species may be noticed the *Notornis Mantelli*, a very large species of the rail family. The first indication of this bird was given by some fragments of the skull found with remains of other birds in superficial deposits of New Zealand by Mr. W. Mantell in the middle island of New Zealand, and the specimen which he obtained is now deposited in the Museum. The greater portion of the bones, as determined by Professor Owen, belong to a genus of birds to which the professor has applied the name of *Dinornis*." An entire skeleton of one of these, the *Dinornis elephantopus*, has been put together by Professor Owen, and is now

* Guide to the Exhibition Rooms, &c.

exhibited in the same room as the huge mastodon and megatherium, together with the legs of a second species, the *Dinornis giganteus*, which must have been from ten to eleven feet high.

Among the more recent accessions may be mentioned the Croizet collection of mammalia from Auvergne, acquired in 1848; the Dixon collection of chalk and tertiary fossils from the south of England in 1851; the Des Hayes collection of older and middle tertiary fossils, from Bordeaux, and the Paris basin, acquired in 1854; Major Cautley's collection of fossil bones from the Himalayas; the Tesson collection of oolites from Normandy, in 1857; and the Bruckmann collection of fossil plants from Oeningen, in 1858. The fossils and minerals together occupy a long gallery called the 'North Gallery,' in the upper story of the building, divided into rooms numbered I. to VI. "The floor of the gallery is occupied by table-cases, which in the rooms I. to IV. contain the collection of minerals; and in rooms V. and VI. are devoted to the fossil remains of invertebrate animals. The wall-cases throughout the gallery are occupied by fossils. The fossil remains are arranged partly in zoological order and partly in geological sequence." They comprise plants, fishes, reptiles, mammalia, insects, and crustacea. These are all arranged in the most approved scientific order, and the collection altogether is, without exception, at present the finest in the world. The unscientific visitor will doubtless admire most the remains of the *Edentata*, quadrupeds without front teeth, as the megatherium; and the *Pachydermata*, or thick-skinned herbivorous quadrupeds, such as the elephants and mastodons, of which there are some very grand specimens in room VI. Another object of attraction in this room, besides the *Dinornis*, above mentioned, is the fossil human skeleton brought from Guadaloupe by Sir Alexander Cochrane, and presented to the Museum by the Lords Commissioners of the Admiralty. This was found imbedded in the solid limestone rock, and much discussion has arisen as to its antiquity, but the most probable conjecture is that it is not more than a few centuries old.

The specimens of *Minerals* in Sir Hans Sloane's Museum were collected at a period when the science of mineralogy was but little studied. Most of them had been chosen for him by persons of little skill, or had been intended to elucidate some system which had become obsolete. For a long time it made little progress, but in 1797, a small collection, made on the north-west coast of America by Mr. Menzies, who accompanied Capt. Vancouver as a naturalist, was presented to the Museum by George III. This collection contained little that was particularly curious, except that it supplied a kind of mineralogical history of an extensive but little explored coast. A systematic collection of minerals for the benefit of persons pursuing the study of mineralogy was not attempted by the trustees till 1799, when they supplied the deficiency of that branch of their institution by acquiring, at the price of 700*l*., a well-chosen collection of minerals of every class, consisting of 7000 specimens, which had been made by Charles Hatchett, Esq., during his travels in various parts of Europe. All that was valuable of the Sloanean collection was incorporated with this ample accession, and with the addition of what the Rev. C. M. Crachet's bequest afterwards supplied, formed, even before the addition of the Greville minerals, a copious and useful mineralogical collection. In 1810 an opportunity presented itself of acquiring the collection of minerals formed by Col. Greville, which were purchased by vote of parliament for 13,727*l*.; and to these collections George IV. added a large and splendid collection of minerals from the Harz Mountains formerly preserved in the Observatory at Richmond.

Two of the greatest rarities of the mineralogical collection are the sculptured tortoise in the centre of the gallery, wrought in Nephritic stone, and found on the banks of the Jumna, near Allahabad, in Hindustan; and a large specimen of meteoric cellular native iron from the province of Atacama, in Peru. There are, however, other specimens of the meteoric iron, some of which have been found in our own country. There are also various beautiful specimens of copper, gold, and silver. "The Siberian and Australian gold regions are well represented, and in particular, the produce of the Victoria gold district of Australia is exemplified in the Latrobe nugget, a mass of *crystallised* gold, of great purity and beauty, weighing nearly twenty-four ounces." The various other minerals, including what are commonly called *precious stones*, are also fitly represented in the Museum collection of mineralogy, which is continually receiving accessions, either by donation or purchase.

The system hitherto adopted for its arrangement, with occasional slight deviation, is that of Professor Berzelius, founded upon the electrochemical theory and the doctrine of definite proportions as developed by him in a memoir read before the Royal Academy of Sciences at Stockholm in 1824. The detail of the arrangement is supplied by the running titles on the outsides of the glass cases, and by the labels within them. There being, however, good reason to suppose that the existing classification is not fully in accordance with the present advanced state of the science, a re-arrangement of the whole collection is contemplated. "But," as stated by the keeper in the parliamentary return just issued (June, 1859), "for such an arrangement to be complete, the collection will need the addition of a considerable number of minerals, either inadequately represented now or not represented at all. The exact and definitive arrangement of a large number of minerals will be impracticable until the means are furnished to the department

for examining the minerals* by those chemical, crystallographic and optical methods, which in the present advanced state of mineralogy, are indispensable for their exact discrimination. Until there is a proper room for chemical, as well as one for crystallographic and optical researches, the arrangement of the minerals can only be provisional."

Botany.—The present extensive collection of dried plants, and other botanical specimens in the British Museum, had its origin in the collection of herbaria, formed from time to time by Sir Hans Sloane during his long life; or at least from the year 1687, when he went out to Jamaica as physician to the Duke of Albemarle, his chief inducement being the opportunity that it would afford him of studying his favourite science. In fifteen months' time he returned to England, bringing with him a collection of 800 species of West India plants, and thus laid the foundation of what was afterwards to become a highly valuable and extensive collection.

The Sloanean herbaria are contained in 336 volumes, bound in 262, and consist of Sir Hans Sloane's collections made by himself in Jamaica and elsewhere, and of various others presented to or purchased by him. Of the latter the most considerable are those of Plukenet and Petiver. Among them there are also large collections made by the Duchess of Beaufort, Kiggalaer, Buddle, Uvedale, and Hawkins; together with numerous smaller ones obtained from many of the principal botanists and travellers of the day. The most interesting are from the collections of Merret, Cunningham, Hermann, Bobart, Bernard de Jussieu, Tournefort, Scheuchzer, Kamel, Vaillant, Kämpfer, Catesby, Houston, and Boerhaave, with the plants presented to the Royal Society by the Company of Apothecaries, in pursuance of the directions of Sir Hans Sloane, for the years 1722-1796. These formed the rent which the Apothecaries' Company paid for the Botanic Garden at Chelsea. The seeds and fruits of Sir Hans Sloane's collection are also extensive and well preserved.

The herbarium of the Baron von Moll, of Munich, in 48 portfolios, was added to the botany of the British Museum in 1815; after which time nothing of importance was received until the acquisition of the Banksian collection in 1827.

The Herbarium of Sir Joseph Banks, of which the larger and arranged portion is contained in cabinets, comprises upwards of 30,000 species. It consists of Sir Joseph's own collections, made during his voyage with Captain Cook; of the Herbaria of Clifford, Hermann, Clayton, Aublet, Miller, and Jacquin; with many of the plants collected by Tournefort, and described in his 'Corollarium.' Aublet's plants were from French Guiana; the collections of Clifford and Hermann were those from which Linnæus formed his 'Hortus Cliffortianus' and 'Flora Zeylanica.' Clayton's Herbarium was that from which Gronovius formed his 'Flora Virginica.' It comprises also the plants collected in the various voyages of discovery subsequent to Sir Joseph Banks's own, with the contributions of numerous travellers; and a collection of plants sent by Loureiro from Cochin China. The Banksian collection alone formed at one time the most valuable assemblage of dried plants in Europe, and is still one of the most important, not only on account of its extent, but as containing the original and authentic specimens of many published species. A collection of flowers and fruits, chiefly of the more rare or succulent plants, preserved in spirits, also form a part of the Banksian department, to the number of upwards of 300 bottles, with a collection of seeds and fruits in a dried state. After the arrival of Sir Joseph Banks's collection, an extensive series of plants was presented by the East India Company, formed and distributed by Dr. Wallich; and another collection of Egyptian plants was presented by Sir J. G. Wilkinson. Numerous additions have been made during the last twenty years, partly by donation and partly by purchase. Among these may be mentioned, a collection of the plants of the East, formed by Aucher-Éloy; of the plants of Greece, by Heldreich; of Persia, by Kotschy; of Siberia, by Karelin and Kirilow; of India, by Drs. Hooker and Thomson; of China, by Fortune; of the Philippine Islands, by Cuming; of Java, by Dr. Horsfield; of New Holland, by Drummond and others; of New Zealand, by Dr. Hooker; of Western Africa, by Don and others; of Southern Africa, by Zeyher and Burke; of North America, by Richardson and others; of California, by Douglas; of Texas and Mexico, by Wright and Fendler; and of Brazil, by Gardner and Spruce.

The additions obtained from these various sources make the entire number of species amount to about 50,000,—sufficient to entitle the Museum collection to rank among the finest in the world.

Previously to December, 1858, no part of this collection was exhibited to the general public. Two rooms however are now appropriated to the purpose, contiguous to the zoological collection, on the upper story. Only one of these, the "first room," is as yet completely fitted up. It comprises many interesting objects, especially "a trunk of *Alsophila Brunonia*, 45 feet in height, from the mountains of Sylhet; two trunks of *Alsophila contaminans*, from the Philippine Islands, with a section of the same from New Guinea; two lofty stems of the great New Zealand Fern Tree, *Cyathea Dealbata*; and another fine species from New Zealand, *Cyathea Medullaris*; the tree-fern of the Cape of Good Hope, *Hemitelia Capensis*; and several specimens of *Dicksonia Antarctica*, one of which is remarkable for the bifurcation of its stem, and another for the curious induration of its central pith." In the wall-cases are "specimens of remarkable Cryptogamic structures, chiefly Ferns, but including

also *Algæ* and *Fungi*;" also "specimens of Palms, including portions of stems and their sections, fronds, spathæ and spadices, and fruits." There is also exhibited a curious selection of specimens, chiefly fruits, preserved in spirit of wine or pyroligneous acid. "Cases 16, 17, and 18, which terminate the series of wall-cases, are devoted to a collection of clay models of English Fungi, made by the late Mr. James Sowerby, while engaged in the publication of his work on that tribe of plants, and representing for the most part the identical subjects depicted in it. The table-cases are chiefly occupied with sections of woods: some of these are what are called cabinet-woods, "including nearly all those which are more or less frequently employed by the London cabinet-makers, and arranged alphabetically, according to the names by which they are ordinarily known in the trade." Other divisions embrace sections of woods from particular countries, as Ceylon, New Holland, New Zealand, British Guiana, &c., arranged in alphabetical order, according to the native names, with the scientific names appended when known. Another division is that embracing "specimens illustrative of diseases, wounds, or other injuries of trees; of their reparation, either in whole or in part; of the results of incisions made through the bark into the wood," &c., &c.

The whole of the departments of the Museum have now been noticed. Those which are open to the general public are open every day in Easter, Whitsun, and Christmas weeks, and on Mondays, Wednesdays, and Fridays in every other week, except the first week of January, of May, and of September, during which the Museum is closed. The hour of opening is ten, of closing four, in November, December, January, and February; five in March and April, September and October; six in May, June, July, and August.

We shall now conclude with some notice of the official publications of the Museum. A synopsis or guide to the different collections appears to have been first issued by the establishment in 1808, and had gone through sixty-three editions by the year 1856. This was edited by the principal librarian, and the description of each department drawn up by its keeper. It is stated in a notice signed by Mr. Panizzi, of the date of January, 1859, that "a synopsis is in course of preparation, which will give a fuller description of the collections visited by the public, will be accompanied by scientific and literary notes, and illustrated by wood-engravings." There are now sold in the Museum a 'Guide to the Exhibition Rooms of the Departments of Natural History and Antiquities,' price 6d., and other "Guides," one to the printed books, one to the autographs and manuscripts, and one to the drawings and prints exhibited in the show-cases, price one penny each.

Of a different description are the volumes which are intended for the use, not of visitors, but students. In the Printed Book Department there are, passing over the obsolete catalogue of 1787, the 'Alphabetical Catalogue of the Library of Printed Books,' by Sir H. Ellis and Rev. H. H. Baber, 7 vols. 8vo, 1813-19; and the 'Alphabetical Catalogue of the Printed Books,' by Mr. Panizzi, vol. i., folio, 1841, containing the letter A only. To these must be added the alphabetical catalogue of the King's Library by Sir F. Barnard, 'Bibliothecæ Regiæ Catalogus,' 5 vols. folio, 1820-29, which was never made an article of sale, but copies of which have found their way to auctions, where they now sell for about 12*l.*, the 'Catalogue of the Geographical Collection, or Maps and Drawings in the Library of King George III.,' 1 vol. folio, or with the same types, 2 vols. 8vo, 1829; and the 'Bibliotheca Grenvilliana,' or catalogue of the Grenville Library, 2 parts in 3 vols. 8vo, 1842-48.

In the manuscript department, are, 'The Catalogue of the MSS. of the King's, or Royal Library,' by David Casley, the under-librarian, 1 vol. 4to, 1734, that of the 'Cottonian MSS.' by J. Planta (superseding a previous one by T. Smith), published by the Commissioners of Public Records, 1 vol. folio, 1802; that of the 'Harleian MSS.' by Humphrey Wanley and the Rev. R. Nares, with a classified index, by the Rev. T. H. Horne, also superseding a previous catalogue, and also published by the Commissioners of Public Records, 4 vols. folio, 1808; that of the MSS. heretofore undescribed, that is, the 'Sloane and Birch Manuscripts,' by the Rev. S. Ayscough, 2 vols. 4to, 1782; that of the Hargrave MSS., by Sir H. Ellis, 4to, 1818; that of the Lansdowne MSS., by F. Douce and Sir H. Ellis, folio, 1819; of the Arundel MSS., and of the Burney MSS. by Rev. J. Forshall, 2 parts forming 1 vol. folio, 1834-40. Instead of printing the catalogues of the additional MSS., after the conclusion of the Ayscough catalogue, they have hitherto been left in manuscript, and an index only has been printed; 'Index to additional MSS., acquired between 1783 and 1835,' by Rev. W. U. Richards and E. A. Bond, 1 vol. folio, 1849. From this time onward there are printed lists of additional manuscripts, one for 1836-40, and one for 1841-45, and written lists of the new acquisitions are prepared for the use of the public in a few months after their acquisition. A separate Oriental catalogue is in progress in the Latin language, 'Catalogus Codicum manuscriptorum Orientalium,' of which part 1, containing the Syriac and Carshunic manuscripts published in 1838, is by Dr. Rosen; part 2, containing the Arabic, commenced by the Rev. W. Cureton, is now being continued by Mr. F. Rieu, and part 3, containing the Ethiopic is by Dr. Dillman. There is also a catalogue of the manuscript music by Mr. T. Oliphant, 1 vol. 8vo, 1842, and a catalogue of the 'Manuscript Maps, Charts, and Plans,' by Mr. J. Holmes, 2 vols. 1844. Part 1, of the 'Greek Papyri in the British Museum' was published by the Rev. J. Forshall in 1839.

In the department of antiquities a 'Description of the Ancient Terra Cottas,' by Mr. Taylor Combe, was published in 1810; and a 'Descriptio Nummorum Veterum,' by the same officer in 1814. He also commenced a 'Description of the Ancient Marbles in the British Museum,' a splendid series of folio volumes with copper-plates, of which ten have now appeared, the first bearing date 1810, and the last 1845. The circumstance that photographs are now taken from the sculptures, and sold by the Museum seems to announce that this undertaking will not be carried on on the same scale and plan, for in nothing does the artist so thoroughly fail in comparison with the sun as in delineating sculpture. The letter-press of the ten volumes comprises a description of the Townley marbles, and the miscellaneous collection of ancient marbles by Mr. Taylor Combe, in the first four volumes; of the room called the 'Columbarium' in the fifth, by Messrs. Combe and Hawkins; of the Parthenon, its metopes and frieze, by Mr. Hawkins, in the three following; and of miscellaneous sculptures, partly of the Townley collection, in the two last, by Messrs. Hawkins, Birch, and Newton.

The departments of Natural History were long unrepresented in the official publications of the Museum—of course, excepting the Synopsis—but the publications of that department are now more numerous than those of all the others. They consist in general of small closely printed volumes, of an unpretending appearance, and sold at moderate prices. One series, the 'List of British Animals,' extends to seventeen parts in small volumes; and from the list given in the 'Guide to the Exhibition Rooms' for 1859, there appear to be no less than fifty-two distinct works or sets of works, either published or in course of publication. The whole are under the editorship of Dr. J. E. Gray, who suggested their preparation.

The unofficial guide-books to the Museum are numerous. One entitled 'A View of the British Museum, or a regular Account relating what is most remarkable and curious to be seen there,' bears no date, but appears to have been issued soon after its opening, and they have grown more abundant of late years than ever. Much has been written on the subject of the Museum in periodical publications at different times. There are articles containing original information in vol. xv. of the 'North British Review,' and in the 'Edinburgh Review' for 1859. But it is certainly remarkable that of so important a building there is no detailed architectural description; and of so important an institution, no history that approaches to amplitude or completeness. The subject is one which abounds in interest of all kinds, but no one has taken it up. It would be impossible to do it justice in narrower limits than those of at least one octavo volume.

BROKEN WIND is a peculiar affection of the *wind* or breathing of the horse, in which the expiration of the air from the lungs, occupying double the time that the inspiration of it does, requires also two efforts rapidly succeeding to each other, and attended by a slight spasmodic action, in order fully to accomplish it. Examination of the animal after death has satisfactorily explained the reason of this. Some of the air-cells, particularly round the edges of the lungs, are ruptured; they have run into one another, and irregularly-formed cavities have thus been made, into which the air may easily enter but cannot without considerable difficulty be expelled. This disease may also be recognised by a characteristic low grunting cough, likewise easily explained by this morbid structure of the lungs.

If the usual breathing has been rendered thus laborious, it is evident that the horse, without skilful management, will be utterly incapable of rapid and continued exertion. In fact, if he is but a little hurried he evinces evident distress, and, if still urged on, he drops and dies; this, therefore, is one of the worst species of *unsoundness*.

The cause of the rupture of the air-cells may be previous inflammation of the lungs, by which a portion of them has been rendered impervious, and thus greater labour thrown on the remaining parts. The delicate structure of the cells, probably weakened by the inflammation in which it had shared, yields to the unnatural distension to which they are thus exposed. Many a horse has become broken-winded when urged to extra exertion immediately after he has been fed; for the air rushing violently into the lungs in the act of sudden and forcible inspiration, and the full stomach lying against the diaphragm, with which the body of the lungs is in contact, their perfect expansion is prevented, and those parts of them, the edges, which are free from this pressure, are unnaturally dilated and ruptured. The kind of food also to which the horse is accustomed has much to do with this disease. If it is comparatively innutritive, a greater bulk of it must be eaten, and the distended stomach will oftener and longer press upon the diaphragm and impede the dilatation of the lungs, or render it unequal in different parts. Thus, broken-wind is a disease of the farmer's horse fed too much on hay or chaff; it is often produced in the straw-yard, where little more than the coarsest food is allowed; but it is comparatively seldom seen in the stable of the coach-proprietor, in which the food is of a better quality, and lies in a smaller compass, and is more regularly administered; and it never disgraces the hunting or racing stable. It must, however, be confessed, that there is sometimes an hereditary predisposition to this disease, consisting in a narrowness of chest, or a weakness of structure in the lungs.

There is no cure for broken-wind; no art can restore the dilated cells to their former dimensions, or build up again a wall between them. But palliative measures may be adopted to a very considerable

extent. The food should be of a more nutritive kind, and lying in a smaller compass. Straw and chaff should be forbidden, the quantity of hay perhaps a little diminished, and that of corn correspondingly increased. A mash should constitute a part of the evening's fare; water should be sparingly given during the day, and exercise should not be required when the stomach is full. Occasional or periodical fits of greater difficulty of breathing should be met by small bleedings and gentle laxatives. By this management, not only will the broken-winded horse be rendered useful for many ordinary purposes, but will be capable of service and labour, which it would otherwise be cruel to require of him.

BROKER, a person who is employed on commission in negotiating mercantile transactions between other parties, generally in the interest of one of the principals, either the buyer or the seller, but who sometimes acts as the agent of both. As it usually happens that individual brokers apply themselves to negotiations for the purchase and sale of some particular article or class of articles, they by that means acquire an intimate knowledge of the qualities and market value of the goods in which they deal, and obtain an acquaintance with the sellers and buyers as well as with the state of supply and demand, and are thus enabled to bring the dealers together and to negotiate between them on terms favourable for both. A merchant who trades in a great variety of goods and products drawn from different countries, and destined for the use of different classes, cannot have the same intimate knowledge for his guidance, and will consequently find it advantageous to employ several brokers to assist him in making his purchases and sales.

Ship-brokers form an important class in all great mercantile ports. It is their business to procure goods on freight or a charter for ships outward bound; to enter and clear vessels at the Custom House; to collect the freight on the goods which vessels bring into the port, and generally to take an active part in the management of all business matters occurring between the owners of the vessels and the merchants, whether shippers or consignees of the goods which they carry. In the principal ports of this kingdom almost all ship-brokers act also as *insurance-brokers*, in which latter capacity they procure the names of underwriters to policies of insurance, settling with the latter the rate of premium and the various conditions under which they engage to take the risk, and receiving from them the amount of their respective subscriptions in the event of loss. When such loss is partial, it becomes the duty of the broker to arrange the proportions to be recovered from the underwriters. The business of an insurance-broker differs from that of other brokers in one particular. The latter, when they give up the name of the party for whom they act, incur no responsibility as to the fulfilment of the conditions of the contract, while an insurance-broker is in all cases personally liable to the underwriters for the amount of the premiums. But he does not incur any liability to make good the amount insured, to the owner of the ship or goods, who must look to the underwriter alone for indemnification in case of loss. Under these circumstances, it is the duty of the insurance-broker to make a prudent selection of underwriters. Merchants frequently act as insurance-brokers.

Exchange-brokers negotiate the purchase and sale of bills of exchange drawn upon foreign countries, for which business they should have a knowledge of the actual rates of exchange current between their own and every other country, and should keep themselves acquainted with circumstances by which those rates are liable to be raised or depressed; and they should besides acquire such a general knowledge of the transactions and credit of the merchants whose bills they buy, as may serve to keep their employers from incurring undue risks. Persons of this class are sometimes called *bill-brokers*, a title which is likewise given to another class of brokers, whose business it is to employ the spare money of bankers and capitalists in discounting bills of exchange which have some time to run before they will become due.

The business of a *stock-broker* is that of buying and selling, for the account of others, stock in the public funds, and shares in the capitals of joint-stock companies. The acts of parliament by which the proceedings of stock-brokers are in certain cases regulated are the 7 Geo. II. cap. 8, and 10 Geo. II. cap. 8; and under these, every bargain or contract for the purchase and sale of stock which is not made *bonâ fide* for that purpose, but is entered into as a speculation upon the fluctuations of the market, is declared void; and all parties engaged in the same are liable to a penalty of 500*l.* for each transaction.

Every person desirous of acting as a broker for the purchase and sale of goods within the city of London must be licensed for that purpose by the lord mayor and court of aldermen. When admitted, the broker must give bond, conditioned with a penalty of 500*l.*, for the faithful discharge of his duties, without fraud or collusion, and to the utmost of his skill and knowledge. He is sworn to this effect, and further binds himself not to deal in goods upon his own account—a stipulation which is very commonly broken. It is the indispensable duty of a broker to keep a book in which all the contracts which he makes must be entered; and this book may be called for and received as evidence of transactions when questioned in courts of law. Each broker pays on admission a fee of 5*l.*, and an equal sum annually so long as he continues to act under his licence: any person acting as

broker without having procured a licence or paid the fees, is liable to a fine of 100*l.* for every bargain which he may negotiate.

It is usual to apply the name of broker to persons who buy and sell second-hand household furniture, although such an occupation does not bear any analogy to brokerage as here described, furniture dealers buying and selling generally on their own account and not as agents for others. These persons do indeed sometimes superadd to their business the appraising of goods and the sale of them by public auction under warrants of distress for rent, for the performance of which functions they must provide themselves with an excise licence, and also conform to the regulations of the 57 Geo. III. c. 93.

The business of a pawnbroker is altogether different from that of the commercial brokers here described. [PAWNBROKER.]

BROMAL. [OTHYL, COMPOUNDS OF.]

BROMANILINE. [ANILINE.]

BROMEIN ($C_{20}H_9Br_4$?). A crystalline substance, little known, obtained by acting with bromine upon crude hydride of phenyl.

BROMETHIONESSIL ($C_{32}H_{14}Br_4S_2$?). An unimportant derivative of hydride of benzoyl.

BROMIC ACID. [BROMINE.]

BROMIDES. [BROMINE.]

BROMINE (Br). An elementary fluid body, discovered, in 1826, by M. Balard, a distinguished French chemist. The name of this substance is given to it from *βρῶμος* (brōmos), a stink or strong smell, on account of its powerful and disagreeable odour: it was first procured by its discoverer from the mother water or bitter remaining after the crystallisation of common salt at the salt-works of Montpellier. It was soon afterwards found in sea-water in the state of bromide of magnesium, and has since been met with in various salt-springs, and especially those of Germany. At Theodorshalle, near Kreutznach, it is found in sufficient quantity to be extracted with advantage, 100 avoirdupois pounds of the water yielding 2 ounces and 80 grains of bromine. Dr. Daubeny has detected bromine in several mineral springs in England, and he states that it occurs in most of those that yield much common salt, except that of Droitwich in Worcestershire. Balard has also found that it exists in marine plants growing on the shores of the Mediterranean, in the ashes of sea-weeds that furnish iodine, and in those of some animals, especially of the *Ianthina violacea*, one of the testaceous mollusca.

Balard obtained bromine by the following process: Into a bottle two-thirds filled with bitter he passed a current of chlorine gas; this decomposed the salt of bromine contained in it, and set the bromine at liberty. He then filled the bottle with sulphuric ether, which dissolved the bromine, and became of a fine hyacinthine-red colour; this was decanted and shaken with a solution of potash, which combined with the bromine; the solution of bromide of potassium thus obtained yielded by evaporation cubic crystals of the salt; these were powdered and mixed with peroxide of manganese and sulphuric acid diluted with half its weight of water; the bromine evolved by this process was received in a vessel of cold water which condensed it. More economical processes have since been adopted, but this is sufficient to explain the principle.

Bromine has the following properties: It is liquid at the usual temperature of the air. Its specific gravity is 2.966. It is poisonous. In considerable bulk, its colour is a deep brownish red; in small quantities, it is of a hyacinthine red. Its odour is extremely strong, greatly resembling that of chlorine: its taste is disagreeable. When exposed to a temperature of 9.5° Fahr., it becomes solid, crystalline, brittle, and hard enough to be powdered. It boils at about 145.4° Fahr., and its volatility is great, for at common temperatures it emits a red vapour resembling that of nitrous acid. The density of this vapour is about 5.340, and 100 cubic inches weigh about 167.4 grains.

Bromine suffers no change by the agency of light, heat, or electricity, and having never been decomposed, it is regarded as an elementary or simple substance. In the decomposition of its compounds by electricity, it is evolved at the positive pole, and consequently resembles in this respect oxygen, chlorine, and iodine, and is like them also in being when vapourised, a powerful supporter of combustion, some substances burning in it as in chlorine gas: its vapour extinguishes a taper; it is soluble in water and alcohol, and especially in ether; it resembles chlorine in destroying vegetable colours. It is very corrosive and poisonous, acting upon and destroying organic matter with great energy. It renders a solution of starch yellow. Its equivalent number is 79.97.

Oxygen and bromine form only one compound, which is

Bromic acid (BrO_3). These elements do not combine directly, but only when exposed to each other in their nascent state. When, for example, bromine is combined with potash, there are formed bromate of potash and bromide of potassium; and when in the same way there are formed bromate of baryta, and bromide of barium, the bromate treated with sulphuric acid yields bromic acid and sulphate of baryta; and the aqueous solution of the acid being slowly evaporated is converted into a fluid of the consistence of a syrup: if the evaporation is carried farther, one part of the acid is volatilised, and another decomposed into bromine and oxygen.

Bromic acid has a scarcely sensible smell. Its taste is sharp, but not caustic. It first reddens, and then destroys, the colour of litmus paper.

Sulphurous and phosphorous acids and the hydracids decompose bromic acid, and set the bromine free. Sulphuric acid also partly decomposes it into oxygen and bromine, because it absorbs the water. Bromic acid is composed of—

Five equivalents of oxygen	$8 \times 5 = 40$
One equivalent of bromine	79.97
Equivalent	119.97

Nitrogen and Bromine. These elements unite to form a detonating oily liquid resembling chloride of nitrogen. Its composition is not known.

Hydrogen and Bromine combine to form

Hydrobromic acid (HBr). This compound is obtained with difficulty by direct action, but at a high temperature these elements slowly unite. Hydrobromic acid may be procured by distilling bromide of potassium with concentrated sulphuric acid; the product is mixed however with bromine and sulphurous acid, because the hydrogen of the hydrobromic acid decomposes a portion of the sulphuric acid. The best method is to mix bromine and phosphorus and a little water; there is produced by their action bromide, or perbromide of phosphorus, which decomposes water, and evolves hydrobromic acid gas, which may be procured in the gaseous state over mercury, or dissolved in water.

Hydrobromic acid may also be abundantly procured by decomposing bromide of potassium with a concentrated solution of phosphoric acid.

Hydrobromic acid gas is colourless, and forms a thick vapour on coming into the air. Its smell resembles that of hydrochloric acid; its specific gravity, according to Berzelius, is 2.731; 100 cubic inches consequently weigh 84.72 grains. It acts upon the metals and their oxides precisely in the same way as hydrochloric acid gas. It is not altered by being passed through a red hot tube, either alone or mixed with oxygen gas. Chlorine separates the bromine from it, and hydrochloric acid is formed. Hydrobromic acid gas is very soluble in water, and the solution has a greater specific gravity than liquid hydrochloric acid; it is colourless, strongly acid, and suffers no change by exposure to the air. Nitric acid decomposes it, and an *aqua regia* is formed, which dissolves gold and platinum.

Hydrobromic acid is composed of—

One equivalent of hydrogen	= 1
One " bromine	= 79.97
Equivalent	80.97

When it is decomposed by potassium, hydrogen gas, equal to half the volume of the acid submitted to experiment, remains, and bromide of potassium is formed.

Chlorine and Bromine form chloride of bromine. It is prepared by passing a current of chlorine gas over bromine, and condensing the vapour arising, by a freezing mixture. It is liquid, has a reddish-yellow colour, lighter than that of bromine. It has a strong, unpleasant smell, and its taste is extremely disagreeable. It is volatile, and soluble in water: the solution possesses bleaching power. It does not possess acid properties, but when mixed with the alkalis forms chlorides and bromides. It has not yet been analysed.

Sulphur and Bromine.—These substances combine readily by mere mixture; the resulting bromide is fluid, has an oily appearance and reddish tint. It emits white vapours when exposed to the air. When moist it reddens litmus paper strongly, but slightly when dry. Boiling water is decomposed by bromide of sulphur, and there are produced hydrobromic, hydrosulphuric, and sulphuric acids. Its composition is unknown.

Phosphorus and bromine combine readily to form two compounds; the terbromide is liquid, and the perbromide is solid. The terbromide (PBr_3) is composed of three equivalents of bromine 239.91, and one of phosphorus 32.02 = 271.93. Both bromides are prepared by mixing these elements in a flask containing carbonic acid gas: action takes place, with evolution of light and heat, and there are formed the solid perbromide which sublimes in the upper part of the flask, while the fluid terbromide remains in the lower part.

The perbromide (PBr_5) is of a yellow colour; by heat it becomes red. It decomposes water, and there are formed hydrobromic and phosphoric acids.

Bromine and iodine form probably two bromides of iodine; the protobromide, or that so considered, is a solid compound, which is by heat convertible into a reddish-brown vapour, condensing into small crystals of the same colour, resembling fern leaves in appearance.

When bromine is added to the above described crystals a liquid is formed, which unites with water and gives a solution possessing bleaching power. It is probably the perbromide of iodine.

We have now mentioned the principal binary compounds of bromine, except those which contain a metal: for these as well as for an account of the bromates which their oxides form with bromic acid, we refer to each particular metal.

Bromine and its compounds are employed in photography, they are also much used in organic chemical research, and the bromide of potassium has been employed in medicine.

BROMIODOFORM (C_2HBr_3). This compound is obtained by treating iodoform with bromine. It is a colourless liquid, which solidifies at 32° to a white mass like camphor. It possesses a penetrating odour, and a saccharine taste.

BROMOBENZOIC ACID. [BENZOIC ACID.]

BROMOBRUCINE. [NUX VOMICA, ALKALOIDS OF.]

BROMOCINCHONINE. [CINCHONA, ALKALOIDS OF; CINCHONINE.]

BROMOFORM (C_2HBr_3). This compound is obtained by distilling a mixture of bromide of lime with alcohol and water. It is a heavy liquid, its specific gravity being 2.10. It is volatile. By potash it is converted into bromide of potassium and formate of potash.

BROMOSALICYLIC ACID. [SALICYLIC ACID.]

BRONAPHTASE ($C_{20}H_7Br$) is one of the numerous compounds obtained from naphthalene. It is formed by the direct action of bromine on naphthalene, care being taken not to add the bromine in excess, which would produce *bronaphtese*. Bronaphtase is a colourless oil, decomposed by chlorine and bromine.

BRONAPHTESE ($C_{20}H_5Br_2$) is formed by the action of bromine on naphthalene, or on *bronaphtase*. It is a crystallisable solid, and forms several compounds with bromine.

BRONAPHTISE ($C_{20}H_3Br_3$) is obtained by heating the bromide of *bronaphtese*.

BRONAPHTOSE ($C_{20}H_4Br_4$), a compound with this formula, has been obtained in two forms, both crystallisable.

BRONCHITIS, inflammation of the bronchi, that is, the tubes which convey air to the lungs. The respiratory organs consist of the windpipe, or the air-tube; of clusters of minute bags called air-cells, which constitute the proper substance of the lungs, and of a delicate but firm membrane which encloses the lungs, as in a sheath, termed the pleura. Each of these component parts of the respiratory apparatus is subject to its own peculiar diseases. Hence the diseases of the respiratory organs are arranged into three classes: first, into those which affect the air-tube; secondly, into those which affect the proper substance of the lung [PNEUMONIA]; and, thirdly, into those which affect its investing membrane, the pleura. [PLEURITIS.]

The air-tube or windpipe is divided into several portions. Each of these portions possesses a peculiar structure, and performs a specific function. Of these divisions the first is termed the larynx, which constitutes the principal organ of the voice, and is situated at the upper part of the neck. Immediately continuous with the larynx is a large tube called the trachea, situated at the fore part of the neck. Opposite the third vertebra of the back the trachea divides into two great branches, named the bronchi, one branch for each lung; the right bronchus going to the right lung, and left bronchus to the left lung.

Each of the bronchi at the place where it enters the lung, subdivides into several branches which penetrate the substance of the lung, where they again divide, subdivide, and spread out after the manner of the branching of a tree. Successively diminishing in size as they subdivide, the bronchi at length form an infinite number of minute tubes, which at their ultimate terminations dilate into the little bags termed the air-cells of the lungs. The larynx, the trachea, the bronchi and their ramifications, together with the cavities of the nose, the mouth, and the pharynx, are all classed together under the common name of the air-passages. All these parts are lined by a membrane, which from the nature of its secretion is termed mucous membrane. In every part of the body the mucous membrane possesses the same essential structure, and is subject to analogous diseases. Accordingly, although the structure of the mucous membrane of the air-passages is somewhat modified in the nose, in the fauces, in the larynx, in the trachea, in the bronchi, and in the air-cells, according to the different functions which it has to perform in these different organs, yet as it possesses in its whole extent the same essential organic characters, so the diseases to which it is subject are perfectly similar. All these diseases may be included under congestion, inflammation, hæmorrhage (effusion of blood from its surface), emphysema (the dilation of the tubes), and polypi (concretions growing from its surface, which obstruct and sometimes nearly obliterate the tubes).

Of these diseases inflammation is by far the most common and the most important. Inflammation of the mucous membrane of the air-passages, is divided into species, according to the nature of the secretion in which the inflammatory action terminates. Thus the inflammation may terminate in a secretion which does not concrete after its formation; this is termed *catarrhal* inflammation. It may terminate in a secretion which instantly concretes as it is formed; this is called *plastic* inflammation or croup: or it may terminate in the destruction of the mucous membrane and the formation of ulcers; this is termed *ulcerous* inflammation.

Catarrhal inflammation, or that in which the inflammatory action produces a secretion which does not concrete, is again subdivided principally according to the colour and consistence of the matter secreted. If the secretion be of a yellow colour, and not tenacious, the disease is called *mucous catarrh*; if the secretion be transparent and viscous, the disease is termed *pituitous catarrh*. When the inflammation is confined, as it often is, to that portion of the membrane which lines the nose, it constitutes the disease commonly known under the name of *cold* or *catarrh*, the technical name of which is *coryza*. When the inflammation extends to the mucous membrane which lines the

fauces, tonsils, and pharynx, the disease is called *cynanche tonsillaris* and *pharyngea*. When the inflammation is seated in that portion of the mucous membrane which lines the larynx, the disease is called *laryngitis*; and when it affects the mucous membrane of the bronchial tubes and their ramifications, it constitutes the disease termed *bronchitis*.

While a common function is performed by the air-passage from its commencement at the mouth and nostrils to its termination in the air-cells, namely, the transmission of air to and from the lungs, additional and very different functions are performed by the several portions of this extended tube. Accordingly inflammation of the membrane that lines it produces widely different effects, according to the portion of the membrane in which the disease is seated; giving rise to the distinct forms of disease just enumerated. The description of these several diseases is given under their respective names; the disease named bronchitis is that at present to be treated of.

Medical writers distinguish between what they term the state of congestion and that of inflammation. In congestion the blood-vessels are merely loaded with a preternatural quantity of blood; in inflammation the blood-vessels, besides being loaded with a preternatural quantity of blood, are in a state of diseased action, which, without any precise knowledge having been acquired of the nature of that action, is termed inflammatory. Simple congestion of the mucous membrane of the bronchi is a frequent affection, which may be induced by any cause that impedes the return of the blood to the left side of the heart. If suddenly and intensely produced, which sometimes though rarely happens, it may prove fatal with all the symptoms of asphyxia [ASPHYXIA]. Several cases are on record in which persons were seized suddenly, without any apparent cause, with extreme difficulty of breathing, which progressively increased until it terminated in death; and on the examination of the body, no morbid appearance could be detected, excepting a general congestion of blood in the capillary vessels of the mucous membrane, of the bronchi and its ramifications. In a slighter form, congestion of the mucous membrane of the bronchi is a constant attendant on various diseases, more especially fever of every type, whether common continued fever, or typhus, or scarlet fever, or measles, or small-pox. In the state of congestion the mucous membrane is preternaturally red, the tinge of colour varying according to the intensity of the affection from a pale to a brownish or purplish red.

When the mucous membrane of the bronchi is in a state of active inflammation, it is of a bright red or crimson colour. This inflammatory redness may be partial or general; but it more commonly affects particular parts of the membrane than its entire surface. Sometimes the redness is confined to the larger bronchial tubes, or it may be limited to the smaller. Sometimes it exists in the bronchus of one side only; at other times it equally affects both bronchi.

Two consequences result from the congestion and inflammation of the membrane: first, the swelling and thickening of the membrane, in proportion to which must of course be an obstruction to the passage of the air; and, secondly, an increase in the quantity of its mucous secretion. This increase and change in the secretion are chiefly the result of inflammation, in some cases of which affection the secretion becomes so excessive as completely to fill up the bronchial tubes, and thereby to occasion suffocation.

The trachea and the bronchial tubes being mere conduits of air, the disturbance of function produced by the inflammation of this portion of the air-passage must of course relate chiefly to impeded transmission of the air. Accordingly difficulty of breathing is the most prominent symptom of inflammation seated in this portion of the air-tube. This difficulty of breathing is proportionate to the obstruction to the passage of the air, which is proportionate to the degree of the swelling of the membrane, and to the extent of membrane involved in the inflammatory affection. If the inflammation be limited to a portion only of a single tube, the difficulty of breathing will not be great; if it affect the whole tubes of one side, the difficulty of breathing will be considerable; if it affect all the tubes of both lungs, the difficulty of breathing may be so great as to prove fatal. Together with impeded respiration, there is a feeling of tightness and oppression across the chest, accompanied with a sense of heat, sometimes amounting to a burning sensation, often referred by the patient to the sternum. Cough is always present. The cough at first is dry, because the membrane is dry; but the secretion soon becomes more abundant than natural. The matter first secreted is acrid; and this acridness diminishes as the quantity of the secretion increases; and when the matter secreted assumes a yellow colour, it is always quite bland; and then the cough is loose and the expectoration free.

When the inflammation is seated in the mucous membrane that lines the cavities of the nose and pharynx, the morbid changes which the membrane undergoes during this process are in some degree manifest to the eye. It is obvious that the part affected becomes redder than natural; that its blood-vessels appear larger, more numerous, and more turgid with blood; at the same time the membrane swells and becomes thicker and firmer than natural. At first it is perfectly dry; for the first effect of the state of inflammation is the suppression of secretion: but soon a transparent thin and acrid fluid is poured out by the inflamed vessels, which irritates and even excoriates all the parts with which it comes in contact. After flowing for a certain time, varying from a few hours to two or three days, according to the intensity of the disease, this morbid

secretion changes its character, loses its acrid nature and becomes more bland, but still remains transparent. In an indefinite time, in general in two or three days, still further changes take place; its bland character remains, but its colour is altered; it gradually assumes a greenish tint; it then passes to yellow, and finally becomes of a bright brimstone hue. As the disease proceeds the condition of the membrane is changed; for as the bland fluid is formed the morbid thickness and firmness of the membrane diminishes, and it gradually returns to its healthy condition.

The redness, swelling, and firmness of the membrane, together with its altered secretions, are then local signs visible to the eye which denote the inflammatory condition of the membrane in coryza and in cynanche tonsillaris and pharyngea. The membrane being in part manifest to our senses in the situations in which these diseases have their seat, we can observe the morbid process that goes on, and mark its different stages. It is probable that a perfectly analogous process goes on when portions of this membrane which are placed beyond our view are inflamed. When the inflammation is seated in the larynx the membrane cannot be seen. That the particular portion of the membrane which lines the larynx is in a state of inflammation is a matter of inference derived from the disturbance of the function of the organ, namely, the function which relates to the formation of the voice. But when inflammation descends further into the trachea, the bronchial tubes and their ramifications, not only are we altogether unable to see the condition of the membrane, but as the functions of those tubes are so simplified as to be mere conduits of air, the only indication we can obtain that they are in a state of disease must arise from the disturbance of that single function, namely, difficulty of breathing. Certainly there will be combined two other symptoms, namely, cough and expectoration; but these are common to various other diseases of the lungs, and consequently cannot be diagnostic, that is, distinctive: while difficulty of breathing is common to every disease of the lungs and heart which has arrived at a certain degree of intensity. When inflammation is seated in these distant portions of the mucous membrane of the air passages, it is impossible to arrive at any certain knowledge of the specific disease from the symptoms or the signs of disordered function only.

It has been shown that inflammation of the mucous membrane of the air-passages has two consequences, first, a swelling of the membrane, and secondly, a change of its secretions; the local signs by which the inflammation of the bronchi and of their ramifications is ascertained and discriminated from all other diseases, have reference to these two conditions.

When the inflammation of the mucous membrane of the bronchial tubes is considerable, the swelling of the membrane may be so great as completely to close that portion of the tube in which the inflammation is seated. The consequence must be that the respiratory murmur [AUSCULTATION] cannot be heard in that portion of the lung which the tube supplies, since no air can pass the obstructed point; accordingly, on applying the ear, or the stethoscope [STETHOSCOPE] to the chest it is found, especially in severe affections of this kind, that the respiratory murmur is absent in various portions of the lungs. This absence of the respiratory murmur is however common to several other affections of the lungs. Hence percussion must be called to the aid of auscultation. By striking the chest [PERCUSSION] it is found that the sound elicited is natural in bronchitis, while in almost every other affection of the lungs it is dull where there is no respiratory murmur. The reason of this difference is, that in bronchitis the cells are filled with air, so that a natural sound is elicited by percussion; but the obstruction occasioned by the swelling of the inflamed membrane confines and prevents the renewal of the air, and consequently the respiratory murmur is lost; while in other affections attended by absence of the respiratory murmur the air-cells are impermeable, either from their consolidation or compression, and then the sound, on percussion, is invariably dull and fleshy. If on the other hand the inflamed membrane be not so much swollen as completely to close the tube, then another and a totally distinct sound is produced—a whistling sound, a sound always observed to accompany an indistinct respiratory murmur, on account of the diminished calibre of the bronchial tube.

Moreover, when the swelling of the membrane diminishes, the nature of the sound is again entirely changed. It now becomes a loud, deep, and sonorous wheezing, the intensity of which is sufficient to cause a vibration upon the parietes of the chest, distinguishable by the hand; at the same time the respiratory murmur becomes more distinct, denoting that the bronchial tubes are more open; finally, the deep sonorous wheeze assumes a still deeper bass, merges into the respiratory murmur, mixes with it, and gives it a roughness which is termed *rough respiration*.

On the other hand, where the secretion re-appears and is in excess, a wheezing sound is produced, which is loud and noisy in proportion to the quantity of fluid poured into the tubes. This sound, when it is formed in the trachea, can be heard through the medium of the air alone; but the application of the stethoscope, or the ear, to the surface of the chest is necessary when it is formed in the bronchial tubes.

Besides these local signs or symptoms derived from the altered condition of the immediate seat of the disease, there are others derived from the disturbance of the system in general. These general or feverish symptoms are lassitude, indisposition to motion, chilliness,

often amounting to shivering, pains in the limbs, and more especially in the back and loins; dullness and heaviness of the mind, or inability to carry on the intellectual operations with the usual vigour. The pulse is rapid and weak, and the urine scanty and limpid. These symptoms are soon followed by irregular flushes of heat, sometimes occurring at one part of the body, sometimes at another, alternating with the cold and intermingling with it, so that the patient feels frequently, in consequence of the rapidity of these changes, the two different sensations in the same place and almost at the same instant. The skin at length becomes universally hot, and commonly dry; headache comes on; there is more or less thirst; the pulse continues rapid, but becomes full; and the urine, which is still small in quantity, is now high-coloured. Then perspiration succeeding to the dry condition of the skin, the functions are again restored in a greater or less degree to their natural condition, and there is a corresponding remission of the symptoms. After this remission there is commonly an accession of the febrile attack, usually in the evening.

The causes which predispose to this disease are whatever causes diminish the general vigour of the system, such as great fatigue, excess of every kind, long exposure to a humid atmosphere, and so on. The great exciting cause is cold, especially when combined with moisture.

With regard to the treatment—when the disease is in its mild form nothing is required but confinement to the house in a uniform temperature in a warm room; demulcent and diaphoretic medicines to determine to the surface; mild aperients, and the abstinence from all stimulating food and drink. When the feverish symptoms have subsided, when all uneasiness of the chest is gone, and the cough is slight, some light tonic, as any of the ordinary bitters, will assist in restoring the strength of the patient, and in preventing a relapse.

When the disease is in its severer form, and dyspnoea, from an overloaded heart, is present, blood-letting is indispensable. The quantity of blood taken must of course be in proportion to the intensity of the disease and the strength of the patient, but it must be in sufficient quantity to relieve the heart. Antimonials exhibited in decided doses immediately after the blood-letting, commonly prevent the necessity of any further depletion. The best preparation of antimony is the tartar emetic, given in solution, to the extent of from a quarter to one grain every second or third hour. The vomiting induced by the first doses commonly subsides or becomes slight after the third or fourth dose. Occasionally, however, this remedy produces so much irritation in the stomach and the system in general that it cannot be given in the quantity necessary to render it efficient; then ipecacuanha forms an excellent substitute, the powder of which may be given in doses of from one to two grains every three or four hours. When the fever subsides, the difficulty of breathing and oppression at the chest continue, blisters are highly advantageous. The cough, in itself teasing and exhausting, and often aggravating every other symptom, must be allayed by oily emulsions, barley water, linseed tea, &c.; and if these fail, and the cough continue so violent as to prevent rest, opium must be given to the extent necessary to subdue it. The opium should always be combined with diaphoretics, so as to determine to the skin, the same time that irritation is allayed. The bowels should be kept moderately open during the whole course of the disease; and there is no remedial measure of greater importance than the maintenance of the apartment steadily and invariably, day and night, at the same point, a point which will insure a moderate degree of warmth, from 65° to 70°. A great degree of heat is a most pernicious stimulus; cold is the great exciting cause of the disease, and any considerable alternation from heat to cold, or from cold to heat, is of itself sufficient to counteract the beneficial operation of the most efficient remedies the most skilfully combined.

(Lænnec on *Diseases of the Chest*; *Lectures on the Diseases of the Lungs*, &c., by Dr. T. Davies; Art. *Bronchitis*; Dr. Copeland's *Dict. of Pract. Med.*; Watson's *Lectures on the Practice of Physic*.)

BRONCHITIS IN ANIMALS, or inflammation of the bronchi or air-tubes of the lungs, is a very serious disease among quadrupeds. It is occasionally confined to the lining mucous membranes of these passages, but it more frequently spreads to the lining membrane of the windpipe and larynx, and to a greater or less degree involves the substance of the lungs.

Horses.—It is not a common disease in the horse, but it is easily recognised by an interrupted wheezing sound in the breathing that can be heard at some distance; a tendency to coldness in the extremities, distinct from the somewhat increased heat of catarrh and the deathly iciness of inflamed lungs; a pulse quicker than either in catarrh or the early stage of pneumonia, not so hard as in pleurisy, but more so than in catarrh or inflamed lungs; the nostrils dilated, and the respiration strangely quickened, being often more rapid than the pulse; a haggard countenance; an almost perfect inability to move, from fear of suffocation; a cough exceedingly painful; a purulent discharge from the nostrils of a grayish-green colour, which soon becomes fetid or mingled with blood; the breath hot; and no expression of pain in any particular part indicated by looking at the side or flank. Pieces of hardened mucus, or organised membrane, are also frequently coughed up.

Bronchitis is sometimes a primary disease, but it is oftener the consequence of a neglected catarrh or long-continued but slight inflammation of the lungs. It is occasionally epidemic. Every affection

of the respiratory organs will then rapidly degenerate into this disease. As it pursues its course, the membrane becomes thickened by inflammation, and the calibre of the bronchial tubes is proportionally diminished, while the mucous secretion is abundantly increased, and consequently the animal dies of suffocation, the air passages becoming completely clogged.

Bleeding should be early resorted to, but very cautiously; for what is true of every mucous membrane is more especially so here—the patient will not bear considerable or rapid depletion. While the blood is flowing, the finger of the veterinary surgeon should be on the sub-maxillary artery, and the vein should be pinned up as soon as the pulse begins to falter: four pounds will scarcely be withdrawn before this will be the case. *Physic* should also be administered, but very cautiously; for the sympathy between the mucous membranes is sooner developed in this case than in any other disease, and a degree of purging is readily excited which bids defiance to all control. Two drachms of aloes should be administered morning and night, until the fæces become softened. The dung having been rendered pultaceous, powdered digitalis, nitre, and sulphur should be administered morning and night, in doses varying according to the circumstances of the case. From half a drachm to two drachms of the first may be given, and from two to four drachms of each of the other drugs.

A blister is indispensable, and it should cover the brisket and sides, and extend up the windpipe even to the throat. The horse should not be coaxed to eat, and nothing more nutritive than mashes should be allowed.

Cattle.—Bronchitis is a still more formidable disease among cattle, and many thousand animals are yearly destroyed by it. The winter cough, which shameful neglect at first produces, and which inexcusable inattention and idleness suffer to continue, almost inevitably terminates in bronchitis or inflammation of the lungs, or both united. The food of cattle is much concerned in the production of it. Mouldy hay and bad straw, the very refuse of the farm, and the common aliment of the yearling cattle, too generally and fatally produce inflammation of the air-passages; and many a beast comes from the straw-yard bearing the seeds of death within him.

The most frequent victims of this disease however are young cattle, yearlings, and especially in low marshy or woody countries. On an upland farm, and particularly on a chalky and loamy soil, it is comparatively seldom known. It oftenest prevails in dry seasons, when the water of the brook fails, and that of the ponds is putrid and filled with animalculæ.

The attack of bronchitis is somewhat sudden; the animal has a dry, husky, and peculiarly distressing cough, and very soon begins to droop and to lose condition. It is painful to see the poor beast standing with his extended head, dilated nostrils, and anxious countenance; violently coughing, almost without intermission, until he is completely exhausted, and falls or dies of suffocation. This state of misery continues from a fortnight to a month. On examination after death, the bronchial tubes exhibit some inflammation, yet far less than could be expected; while, characterising the disease, and fully accounting for all its distressing symptoms, these passages and the wind-pipe, and often the larynx and the fauces, are filled with small worms, forming a kind of coat mixed with the mucus, or connected together in knots of various sizes. The disease is either produced or much aggravated by the presence of these worms and the irritation which they produce.

These worms belong to the Nematoid group, and have been named *Filaria bronchialis* and *Strongylus levigatus*. They are of a thread-like form, from half an inch to two inches in length; the body round, the head obtuse, the mouth circular, and surrounded with minute barbs, or elongated papillæ; the tail of the female pointed, and that of the

male somewhat rounded and oblique. The female usually contains a great number of eggs; and a few of the ova, but so few as to appear to have been deposited there accidentally, are occasionally found enveloped in the mucus of the windpipe and the air-passages of the lungs. Of the natural history of this worm nothing is known, but the fact of the impregnation of the female shows that this is the last if not the only state of its existence.

The ova, or the minute worms, are received from the pastures, or, more probably, from the water, when stagnant or loaded with animalculæ. Being alive, it is probable they escape the digestive powers of the stomach, and mingle with the blood, and thread the various circulatory passages until they arrive at a congenial abode; or the ova may be hatched by the warmth and moisture of the mouth, and then wind their way to their destined residence.

The modes of cure are evident: we should either destroy or remove these intruders, or strengthen the animal so that he shall bear up against the irritation which they excite; for it is well known to the farmer that if the patients, by the natural power of their constitution, or by the application of certain means, can struggle with the disease until the cold weather sets in, and the worm dies, or must find another residence, they will eventually recover. The pasture should be changed as soon as the disease is discovered. The supply of fresh recruits will be prevented, or possibly that deleterious matter, whether connected with the water or the pasture, which is necessary to their thriving and multiplying, will be no longer obtained. The simple change of pasture in an early stage of the disease has saved thousands of young cattle.

If however these parasites have so far established themselves as to resist this mode of attack, it must be considered whether some agent cannot be brought into actual contact with them, which will either destroy them, or so far annoy and weaken them that they will loosen their hold and be expelled by the convulsive coughing of the calf. The most obvious method of accomplishing this is, to cause the patient to breathe some pungent and deleterious gas, such as that produced by the burning of sulphur or the evolution of chlorine. By both of these fumigations the worms have been quickly and perfectly destroyed, but there is considerable care required in the management of these experiments; inflammation in the air-passages, very difficult afterwards to allay, has been produced, and occasionally the beast as well as the worm has been destroyed. This mode of treatment should therefore be considered as a last resource, and should never be intrusted to inexperienced hands.

Common salt readily destroys many species of worms, and is conveyed through the circulatory vessels in a sufficiently pure state to expel these vermin from the air-passages: at the same time it is an admirable tonic, and supports the decaying strength of the animal. The most powerful vermifuge however in these cases is lime-water, and if half a pint of it, with a couple of ounces of common salt, is given to each patient every morning, attention being paid to a change, and perhaps a repeated change of pasture, and to the comfort of the animals in other respects, the majority of them will be saved.

This disease occasionally appears in lambs, deer, and swine. The mode of treatment should be the same as for calves.

BRONCHOCELE (*Βρογχοκήλη*), from *Βρόγχος* (bronchos), *throat*, and *κήλη* (cèle), a *swelling*; called also Goitre and Derbyshire Neck; a swelling in the upper and fore part of the neck, occasioned by a preternatural enlargement of the thyroid gland. The tumour is free from pain, generally of the natural colour of the skin, does not readily inflame, and is not of a malignant character. Often the swelling is rather a deformity than an inconvenience; but occasionally, and especially when the tumour is large, it causes serious evil, by obstructing the voice and the respiration.

When the swelling first appears, it is soft, spongy, and elastic; after some time it assumes a more firm and fleshy consistence, being however firmer in some places than in others, and it gradually spreads towards each side of the neck until it attains in some cases a prodigious magnitude. In general the swelling affects the whole gland, but occasionally only one lobe is enlarged. When the swelling attains a great size, and the lower part of the gland is more especially involved in the disease, the tumour hangs pendulous from the neck. On examining the interior of the gland, it is found to consist of innumerable cells of different sizes, which are all filled with a transparent viscid fluid. Nothing is known of the real nature of this disease. Little is ascertained of the causes which either predispose to it or which produce it. Many causes are assigned, which is commonly the case when no cause is known. Moreover, in the present instance, several of the causes assigned are contradictory. What is certain is, that there are countries, or rather particular places in certain countries,—for example, Switzerland, Savoy, the Tyrol, certain districts of South America, and some places in Great Britain, as Derbyshire,—in which the disease is *endemic* (common to the inhabitants of the same country, from some cause specially connected with that country). It is much more common in females than in males. In Great Britain it is very seldom seen in males, but in Switzerland, and in other places in which it is very prevalent, males are more often attacked than in Britain. It commonly occurs about the age of puberty, and in girls seems to be strictly connected with an irregularity in the female health. Dr. Copland says, "In a considerable number of cases which have come before me in females, I have never met with any before the period of commencing puberty,—not even at the Infirmary for Children; although the menses have often been delayed for a year or two, or even longer, when the tumour has appeared at this epoch; and I have seldom observed an instance in this sex unconnected with some irregularity of the menstrual discharge or disorder of the uterine functions. In two cases occurring in married females, who were under my care, unhealthy or irregular menstruation had existed during the

continuation of the goitre; in one case for eight years, in the other for five; upon its disappearance pregnancy took place in both. Suppression of the menses has sometimes caused its sudden appearance and rapid development; and it more rarely has originated during pregnancy and the puerperal states. Authors have added conclusive proofs of its occurrence hereditarily, independently of endemic influence."

It has been said to have an intimate connection with poverty and bad food, the rich being comparatively exempt from it; but on this point the statements are conflicting. It has been very generally attributed to water used as drink, and more especially to snow-water; but the disease occurs where there is no snow, as in Sumatra and several parts of South America; the Swiss who drink snow-water are free from the disease, while those who use hard spring-water are prone to it. In his journey to the Polar Sea, Captain Franklin observed that at a part where bronchocele prevails, the disease is confined to those who drink river-water, while those who use melted snow escape. Mr. Bally ascribes its frequency in a district in Switzerland to the use of spring-water impregnated with calcareous or mineral substances; and he states that those who use not this water are free from both goitre and cretinism. Dr. Coinder observed that the inhabitants of Geneva, who drink the hard pump-waters, are those most liable to bronchocele. Its prevalence in Nottingham is ascribed by Dr. Manson to the same cause; which also seems to occasion it in Sussex and Hampshire, in the valleys of which counties it is frequently met with.

It is unquestionably most frequent in low, moist, marshy, and warm valleys; even in the very districts in which it is endemic, the inhabitants of dry and elevated situations are exempt from it; but it is probable that the malaria of those places operates only as a predisposing cause, favouring the action upon the system of some unknown agent.

It is frequently connected with a tendency to scrofulous disease in this country, and is found in conjunction with cretinism in the Swiss valleys. [CRETINS.]

One of the most efficient remedies for the removal of bronchocele is iodine. It should be administered internally, and may be applied in the form of ointment externally. Iron and quinine may be combined with this treatment with advantage; but above all things, pure air is the most important.

Sometimes the larger forms of bronchocele resist all medical treatment, and, threatening life by pressure on the air-passages, they have been successfully removed by the surgeon's knife.

BRONCHOTOMY. [TRACHEOTOMY.]

BRONZE, an alloy of copper, tin, occasionally zinc, and a little lead. For casting statues, bronze has been used from the most remote antiquity. According to Pliny, this art was brought to a considerable degree of refinement 700 years before the Christian era. Ancient military weapons and tools were also frequently made of it. For the latter purposes steel has superseded this alloy, and bronze, strictly so called, is now used for little else than the casting of statues and medals. *Bell*, *gun*, and *speculum metal*, all largely used, are however merely varieties of bronze, and will be severally treated of in this article.

The essential characteristics of a metal to be used for statuary purposes are obvious. It must flow freely when melted and expand on solidifying, in order that the minutiae of the mould may be accurately represented. It must be so tough and hard that it will be but little affected by accidental blows, and be composed of such substances as will yield an alloy on which the weather will have the least possible influence. All these requirements are exactly fulfilled by bronze: moreover, the slight action of air and moisture on this alloy by long exposure give to the statues a greenish tint, that to the eye is more agreeable than otherwise.

The following are specimens of the proportions of copper, tin, &c., which may be used in the manufacture of bronze; they may be slightly varied, according to the purposes for which the alloy is intended:—

	I.	II.	III.
Copper	96	89	87.25
Tin	4	8	9.75
Zinc		3	3.00
	100	100	100.00

No. 1 is the formula recommended by M. Chaudet: a bone-ash mould furnishes a perfect impression that only needs polishing. No. 2 assumes an antique appearance by age. No. 3 is an average of the proportions now generally used for medals. The celebrated statue of Louis XV. contained—

Copper	82.45	} Specific gravity 8.482
Zinc	10.30	
Tin	4.10	
Lead	3.15	
	100.00	

Small quantities of bronze may be melted in crucibles,—large masses on the hearth of a reverberatory furnace. The molten metal should be occasionally stirred to prevent separation into layers, and the whole operation conducted as quickly as possible, to prevent waste of copper

and tin by oxidisement, and zinc by volatilisation. This effect may also be prevented to a very great extent by covering the whole with a layer of small charcoal.

Gun- or Cannon-metal.—The best proportions of copper and tin for this alloy seem to be about nine of the former to one of the latter. Zinc and lead are never added. A larger quantity of copper causes the masses to separate on cooling into two layers; this may be avoided by very sudden cooling in thick iron moulds, or in water; but large cannon cannot be treated in this way.

Bell-metal always contains a much larger amount of tin than gun-metal. When suddenly cooled, it is soft, tough, and malleable, and in this state may be turned in a lathe and worked with considerable ease. By re-heating and slow cooling it is obtained hard, brittle, and sonorous. Some of the best specimens of bell-metal consist of—

	I.	II.	III.	IV.	V.
Copper	78	82	80	75	72.00
Tin	22	18	10.1	25	26.56
Zinc			5.6		Iron, 1.44
Lead			4.3		
	100	100	100.0	100	100.00

No. 1 is very fusible and sonorous. No. 2 is the composition of the Chinese *gong-gongs*; it should be very suddenly cooled. No. 3: old English bell-metal. No. 4: excellent for church bells. No. 5: proportions, according to M. Berthier, of the ornamental French clocks or pendules. For similar purposes, a little zinc increases the sharpness of the tone.

Speculum metal, used in the preparation of specula for reflecting telescopes, has still less copper and more tin than bell-metal. It frequently contains also a little metallic arsenic, which is supposed to render it whiter; thus:

	I.	II.	III.	
Copper	64.5	66.6	68.2	} or (Cu ₄ Sn)
Tin	32.2	33.4	31.8	
Arsenic	3.3			
	100.0	100.0	100.0	

The proportions in No. 3 were used by Lord Rosse in the manufacture of his celebrated reflector.

The materials of speculum-metal should be thoroughly incorporated when in the melted state by brisk stirring with a wooden spatula, and the mould so arranged that the bottom shall receive the intended upper surface of the mirror; this part will therefore cool first, and give the most perfect casting. This variety of bronze is exceedingly brittle, a slight blow, or the incautious application of even a gentle heat, causing its fracture; the polishing of specula must therefore be performed with great care. For this operation, Mr. Potter recommends peroxide of iron, prepared by precipitating sulphate of iron with ammonia, washing the precipitate with water, and heating to dull low redness.

Composition of varieties of ancient bronze:

	a	b	c	d
Tin	12	22.02	19.66	26.74
Copper	88	77.60	80.27	73.00
	100	99.62	99.93	99.74
	e	f	g	h
Tin	26.0	19.5	3	15
Copper	71.0	80.5	97	85
Zinc	1.8			
Iron	1.2			
	100.0	100.0	100	100

a. Bronze from Celtic vessels, swords, and spears. (Clarke, 'Ann. Phil.,' 7, 73.) b. Arrow-head from an Egyptian tomb. c. Cast coffin from Altai, on the borders of China. d. Another coffin. (Göbel, 'Schw.,' 60, 407.) e. Old bell at Rouen, known by the name of *Cloche d'Argent*. (Gerardin, 'Ann. Chin. Phys.,' 50, 205.) f. Chinese *gong*. (Thomson, 'Ann. Phil.,' 2, 209.) g. Bronze springs for the Balistæ, according to Philo of Byzantium. h. Antique sword, found in the environs of Abbeville.

Bronze is slowly attacked by boiling hydrochloric acid, tin being extracted, leaving copper containing a small quantity of tin. Nitric acid dissolves it readily.

BRONZE, Ital. *bronzo*; Fr. *bronze*; Gr. χαλκός (chalcos); Lat. *æs*, is essentially a compound of copper and tin, which metals appear to have been among the earliest known. Copper is not unfrequently found in its metallic state, and fit for immediate use; and tin, though not so met with, often occurs near the surface, and its ore is easily reduced. These metals, though neither of them possesses the hardness requisite for making instruments either for domestic or warlike purposes, appear to have been early found capable of hardening each other by combination; the bronze, which is the result of this combination, consisting of different proportions of them, according to the purposes to which it is to be applied.

Bronze is always harder and more fusible than copper; it is highly malleable when it contains 85 to 90 per cent. of copper; tempering increases its malleability; it oxidises very slowly even in moist air, and hence its application to so many purposes. The density of bronze is always greater than that of the mean of the metals which compose it: for example, an alloy of 100 parts of copper and 12 parts of tin is of specific gravity 8.80, whereas by calculation it would be only 8.63.

The precise etymology of the word "bronze" has not been ascertained; but it is first met with in Italian writers to express this mixture of metals, and it is not very improbable that it is a corruption from the Italian *bruno*, which signifies *brown*; the bronze of the Italian, and particularly the *cinque cento* schools, being of that colour which is nearly the original tint of the material when left in its natural state. The green hue that distinguishes ancient bronzes is acquired by oxidation and the combination of carbonic acid: and the moderns, to imitate the effect of the finer antique works, sometimes advance that process by artificial means; usually by washing the surface with an acid. Vasari alludes to this practice among the artists of his time, and to the means they adopted to produce a brown, a black, or a green colour in their bronze. ('Vit. dei Pittor.' Introd.) The Greeks and Romans, in speaking of works in bronze, used words which at once referred to the metal; the Greek *chalcos* being a mixture of copper and tin, and the Roman *æs* the same. These words are often understood by moderns to denote brass, which is however a different composition, being a mixture of copper and zinc.

Though there is no doubt that the uses of some of the metals were known very early, there is unfortunately little or no information either on the mode of working them or of the time of their discovery. It is clear however that, for a long period, copper, if not the only metal known, was at least the most abundant; for we find it was employed universally for arms, ornaments, and utensils, domestic and agricultural. Iron was apparently of much later discovery. The simpler processes of metallurgy seem to have been practised at a very remote date both in Asia and Egypt. On this subject the Old Testament is our best authority, and the accounts we there find lead us to believe that considerable skill had been attained by the very earliest nations. Tubal-cain was, we are told, a great worker in metal. Among the earliest allusions to works in metal in the Books of Moses is the mention made of the presents offered to Rebecca: Abraham's servant gave her "a golden ear-ring of half a shekel weight, and two bracelets for her hands of ten shekels weight of gold;" and spoke to her of his master's riches, particularly mentioning silver. (Gen. xxiv. 22.) The accounts of the ornaments and utensils in the history of Jacob, and of Joseph, and in various other passages of the Old Testament, prove in like manner the extensive employment of metals at that time; and their being applied to purposes of luxury indicates that considerable progress had been made in the art; long use naturally preceding any attempt at refinement. The earliest recorded names of sculptors (and they are metal-workers) are in the Old Testament. One was "Bezaleel, of the tribe of Judah, who was filled with the spirit of God, in wisdom, and in understanding, and in knowledge, and in all manner of workmanship, to devise cunning works, to work in gold, and in silver, and in brass," &c. &c.: with him is associated Aholiab, of the tribe of Dan. They were the artists appointed to execute the works of the Tabernacle. (Exod. xxxi.) Among the Egyptians also the employment of metal was known in times prior to any historical record; and it is probable that the metallurgical knowledge possessed by other countries was derived directly or indirectly from this source. Among other proofs of this, the casting of the golden calf by the Israelites may be cited. It is remarkable, however, that among the remains of bronze works of art that have been discovered in various parts of Egypt, none have been found of large dimensions. Some of the most remarkable early works in metal mentioned in history are those recorded by Diodorus Siculus, who in this part of his history followed Ctesias, a Greek historian and physician contemporary with Xenophon. He describes works in gold and bronze which decorated the gardens of Semiramis, of such a magnitude, and representing so great a variety of subjects, that, if we are to place any confidence at all in the testimony of this writer, we must conclude that the Assyrians and Babylonians had attained very great proficiency in the arts connected with metallurgy. That the statements of Diodorus, which in fact are those of Ctesias, are to be received with some qualification, must be granted; but Mr. Layard found in the course of his excavations at Nineveh various bronze ornaments which had evidently been cast in a mould: several of these are in the British Museum. M. Botta also discovered among other metal articles in the palace of Khorsabad, a very finely moulded bronze lion.

The skill and enterprise of the Phœnician people gave them a commanding station among the ancient nations, and they must have materially influenced the civilisation not merely of neighbouring but of remote countries; but unfortunately the monuments that can be referred to a Phœnician origin are too few, and for the most part of too distant a date from the brilliant epoch of the Phœnician nations to be fairly quoted as specimens of original taste or practice. Their supposed traffic with Britain furnished them tin, or probably they procured it from Spain or Eastern Asia. Homer has immortalised the Sidonians with the distinguished title of "Σιδόνες πολυδαίδαλοι," *the Sidonians the skilful workers*. The artificer employed by Solomon in

the decoration of the Temple (about 1000 years before our era) was Hiram, a native of Tyre, "who was cunning to work all works in brass." (1 Kings vii.) These works, we are told, were *cast* and wrought.

We know so little of the earlier history of the arts in India, that we must be satisfied with observing that many specimens of their bronze works, of which we possess some curious examples in this country, as idols, utensils, &c., may be referred, without doubt, to an extremely remote date; but the slight changes that have taken place in the style of their art and workmanship prevent any classification of them, or even an approximation to the times at which any of the more ancient were executed.

The works that remain of the Greeks, whether considered with reference to the illustration of their history, or for the exquisite specimens which they offer of their taste and feeling in imitative art, claim our especial regard, and the names of few sculptors, or rather statuarys, of celebrity have reached us who were not chiefly distinguished for the excellence of their productions in bronze. In the time of Homer, the scarcity of iron occasioned the general use of other metals; and we find the arms, offensive and defensive, are always described as being made of bronze, or perhaps copper alone, which it is possible they had some means of tempering and hardening. The art of casting statues seems to have been first practised in Asia Minor; Greece, properly so called, being probably too uncivilised to undertake such works. The Lydians and the Phrygians were early distinguished for their skill in these arts, and they were probably the teachers of the Greeks.

The records to be depended upon as to Greek art go as far back as between 600 and 700 years B.C., and the mode of working metal at that time seems to have been the same, or nearly so, as far as there are means of judging, as that adopted by other and earlier nations. The first and most simple process appears to have been hammer-work; that is, lumps of the material were beaten into the proposed form; and if the work were too large to be made of one piece, several were shaped, and the different parts fitted and fastened together by means of pins or keys. Pausanias (iii. 17) particularly describes this process in speaking of a very ancient brass statue of Jupiter, at Sparta; and this mode of working (mentioned by Herodotus, vii. 69) is called by him and others *σφυρήλατον* (*sphurêlaton*), "hammer-worked," in opposition to the term *ἐργα χωνευτά* (*chōneutá*), applied to "works that were cast." This statue of Jupiter was the work of Learchus of Rhegium, and Pausanias says it was the most ancient statue of the kind; by which he probably only means that it was of the most archaic or ancient style, as Herodotus, Diodorus Siculus, and others, as well as Pausanias himself, refer to other works of a more remote date. Pliny (xxxiii. 4), in speaking of a solid gold statue of Diana Anaitis, refers to a mode of execution termed *Holosphyraton* (derived from three Greek words, signifying "entire," "solid," and "hammer"). It was so called probably to distinguish it from another kind of hammer-work, in which plates of metal were beaten out into the form desired on a nucleus of another material, of which, as some believe, a curious specimen of ancient Egyptian workmanship may be seen in the British Museum. This process is alluded to in Homer ('Odys.' iii. 425); and as early as Moses, the brazen censers of the disobedient were, by the lawgiver's command, *beaten out into plates* for covering the Tabernacle. The most ancient civilised inhabitants of India seem to have adopted the same manner of working in laminæ, or plates; there is an example of it in the British Museum, in a figure of Buddha. A great saving of metal was effected by this process.

Soldering (*κόλλησις*), or the art of uniting the parts of metals, is attributed (Herod. i. 25) to Glaucus of Chios, a contemporary of Alyattes, king of Lydia. The art of soldering iron is attributed solely to Glaucus. (Compare Pausan. x. 16. with Herod. i. 25.)

It is extremely difficult to determine when the art of metal-casting in regular moulds was first practised. It was undoubtedly known very early, though its adoption in European Greece is probably of a comparatively late date. Its progress was evidently marked by three distinct stages. The first was simply melting the metal into a mass, and then beating it out either as solid hammer-work, or in plates. The next was casting it into a mould or form; the statue being of course made solid. The last, which argues considerable knowledge and skill, was casting it into a mould, with a centre or *core* to limit the thickness of the metal. The first artists who are celebrated by the historians of Greek art for their success in metal-casting are Rhœceus (who is said to have invented the casting of metal), Theodorus, and Telecles, natives of Samos (Herod. i. 50; Paus. viii. 14; Plin. 'N. H.' xxxv. 12); and the manner in which they are spoken of proves that their works were held in high estimation long after their own time. There is some difficulty in fixing their date with precision, as there were two or three of the same names, but it seems probable that the first artists so called lived between 700 and 600 B.C. Theodorus is made by Herodotus the contemporary of Crœsus, who was defeated by Cyrus B.C. 557. Gitiadas of Sparta and Glaucias of Ægina hold also a distinguished rank among the earlier artists in bronze; to whom we might add a long list. Herodotus (v. 77) says that four bronze horses were made by the Athenians from the tenth part of the value of the ransom of the Boeotians and Chalcidians: the horses were placed at the entrance of the propylæa on the Acropolis, with an appropriate inscription. The

ancient artists do not appear to have considered it important to cast their statues entire, for Pliny acquaints us with the composition used for soldering the parts together. The finest collection of ancient bronzes, taking it as a whole, is at Naples; among the specimens there are some very curious for the manner in which the ringlets of hair, worked separately, are fastened on; many of these are the size of life. Bronze-casting seems to have reached its perfection in Greece about the time of Alexander the Great, 330 B.C. The accounts given of the works executed about that time almost exceed credibility. After Lysippus, the favourite sculptor of Alexander, who executed, according to Pliny (xxxiv. 8), above 600 works, the art declined.

The ancient statuary seems to have been extremely choice in their selection and composition of bronze. Two of the most celebrated, contemporary with Phidias, carried their rivalry so far as to employ bronze of different countries; Polyclethus preferring that of Ægina, while Myron always used that made at Delos. The ancients seem to have had a method of running or welding various metals together, by which they were enabled to produce more or less the effect of natural colour. Some works are described that were remarkable for the success which attended this curious, and to us unattainable, process. They also tinted or painted their bronze, with the same view of more closely imitating nature. (Callistrat., Stat.; Plin. xxxiii. 9; Plut., 'Symp.' lib. v., and others; see also Quatremère de Quincy, 'Jup. Olymp.') The story of the accidental mixture of the most precious bronze used by the ancients, namely the Corinthian, has been too often repeated to require further notice here. Pliny himself refutes the story which he records. He informs us also that there were three sorts of the Corinthian bronze. The first, called candidum, received its name from the effect of silver which was mixed with the copper; the second had a greater proportion of gold; the third, Pliny says, was composed of equal quantities of the different metals. The ancient writers mention several of the bronzes that were used; amongst them we find Æs Hepatizon, or liver-coloured; Æs Deliacum, and Æs Ægineticum—Plutarch says the composition of the Delian brass was a secret lost in his time—Æs Demonnesium, Æs Nigrum, and lastly Tartessian bronze (Ταρτησσιος χαλκός), of which, it must be confessed, we know little or nothing beyond their titles. The analysis of a few specimens of bronze of undoubted antiquity, namely, a helmet with an inscription (found at Delphi, and now in the British Museum), some nails from the treasury of Atreus at Mycenæ, an ancient Corinthian coin, and a portion of a breastplate or cuirass, of exquisite workmanship, also in the British Museum, affords about 87 or 88 parts copper to about 12 or 13 of tin per cent. The experiments of Klaproth and others give nearly the same results as to ingredients; the quantities sometimes differ slightly; lead is contained in some specimens. Zinc has not been found in any quantity sufficient to warrant a belief that it was intentionally introduced: indeed, it is thought that its nature was not understood by the ancients. In an antique sword found many years ago in France, the proportion in 100 parts was 87.47 of copper to 12.53 of tin, with a portion of zinc so small as not to be worth noticing (Mongez, 'Mém. de l'Institut'). The same may be observed of minute portions of silver that have sometimes appeared in bronze. ('Antichit. di Ercolano.')

The Romans never attained any great eminence in the arts of design. Their earliest statues were executed for them by Etruscan artists. Rome however, as the conquests of that warlike people were extended, was soon filled with a prodigious number of works of the best schools of Greece; and artists of that country, unable to meet with employment at home, settled in the capital of the West. Zenodorus executed some magnificent works in the time of Nero, particularly a colossal statue of the emperor, 110 feet high. But Pliny, who lived in the reign of Vespasian, laments the decline of the art and the want of skill of the artists in his time. It is even said that the art of casting bronze statues was lost. This assertion is, however, totally unfounded; for it appears that a Greek sculptor, Celon, was highly distinguished under Domitian, and one of his works, a colossal equestrian statue cast in bronze, is much celebrated; and there is no doubt that the art was well known under Trajan, Hadrian, the Antonines, and even much later.

The practice of gilding bronze statues does not seem to have prevailed till taste had much deteriorated, and when the richness of material was more highly thought of than the excellence of workmanship. Pliny tells us that Nero commanded a statue of Alexander, by Lysippus, to be gilt; but when done it was found to have so much injured the effect or beauty of the work, that the gold was by the emperor's orders removed. The injury was doubtless occasioned by the glitter and sparkling of the light upon the projecting and shining surfaces, destroying the breadth, and consequent grandeur and unity of effect secured by the more sober colour of the bronze. The practice of art among the Romans declining rapidly, and with but few interruptions, ceases to interest us about 200 A.D. In the beginning of the 13th century, at the taking of Constantinople, we read that some of the finest works of the ancient masters were purposely destroyed, either with the object of converting the material into money, or for sale to the brass-founders, for the mere value of the metal. Among the few works saved from this devastation are the celebrated bronze horses, which now decorate the exterior of the church of St. Mark at Venice.

Passing over the intermediate age of darkness and barbarism, we arrive at the epoch of the revival of art in Italy, under the Pisani and others, about the 14th and 15th centuries. The celebrated bronze gates of the Baptistery at Florence, by Ghiberti, which M. Angelo said were fit to be the gates of Paradise, are among the more remarkable works of the time. In the succeeding century we find Guglielmo della Porta practising the art with so great success, that he obtained the flattering notice of Michel Angelo; and he is distinguished by Vasari ('Vit. di Leone Leoni') for adopting a mode of casting that was considered quite original, in executing his colossal statue of Paul III. The metal, when run from the furnace, was carried downwards by a duct, and then admitted into the underside or bottom of the mould (nel bagno da basso); and thus, acted upon by superior pressure, as in a common fountain, was forced upwards till the mould was entirely filled. It is necessary in this process that the mould should be kept in a state of great heat, in order that the metal may not cool before the whole is run. But among the artists who are celebrated for their skill in bronze-casting, Benvenuto Cellini holds a most distinguished rank: there are few collections that cannot boast some specimens of his smaller productions, while the larger works that remain, particularly at Florence, prove that his high reputation was not undeserved. In his interesting and romantic autobiography he gives some curious particulars on metal-casting; and an anecdote which he tells respecting one of his works illustrates an important fact in the process, while, at the same time, it is highly characteristic of the impetuosity of the man. Copper alone is thick and pasty, and therefore incapable, without some alloy, of running into all the cavities and sinuosities of the mould; a small mixture of tin is therefore usually added to give it the quality necessary for producing what is called a true cast. He was engaged on his fine group of Perseus and Medusa, during which, by the jealousy of rivals and the ill-conduct of his workmen, he had been subjected to every kind of annoyance and disappointment. At length his labours seemed to be nearly at an end: his mould was lowered into the pit, the furnace heated, and the metal thrown in. At this time, while a violent storm raged without, the roof of his study, as if to increase the confusion, caught fire; but though ill and harassed, he still directed the works and encouraged his assistants, till overcome by anxiety and fatigue he retired in a raging fever to lie down, leaving instructions respecting the opening of the mouth of the furnace, and the running of the bronze. He had not, he says, been reposing very long before one came running to him to announce evil tidings: the metal was melted but would not run. He jumped from his bed, rushed into his studio like a madman, and threatened the lives of his assistants, who being frightened got out of his way, till one of them, to appease him, desired him to give his orders and they would obey him at all risks. He commanded fresh fuel to be thrown into the furnace, and presently, to his satisfaction, the metal began to boil. Again however it appeared thick and sluggish, and refused to run. He then ordered all the plates, dishes, and other articles of domestic use in his house to be brought to him, which he threw pell-mell on the metal, when it immediately became fluid and the mould was soon filled. He adds, that he fell down on his knees, and poured forth a fervent thanksgiving to Almighty God for the success that had crowned his exertions. In the processes above described the metal was allowed to flow at once from the furnace into the channels or ducts of the moulds. The statue of Louis XIV., by Girardon, one of the most celebrated sculptors of France, was cast somewhat differently, though with equal success. The wax which regulated the thickness of the metal being entirely melted out, and the mould fixed in the pit, with the necessary vents for the escape of the air, the metal was allowed to run from a furnace, placed considerably above, into a sort of trough or basin. In this were three apertures, closed by plugs, immediately over the chief channel or conduit by which the metal was to be conveyed into the mould. These, by a mechanical contrivance, were opened simultaneously, when the metal descended at once into the mould. This group was cast entire.

The more modern practice of the English, French, Italian, and German artists does not differ materially in its principle from that of the earlier Italians. Some however use what is called a cupola-furnace, and others a blast-furnace. The mode practised in Sir R. Westmacott's foundry, where many of the chief colossal as well as other works that have been produced in this country have been cast, will serve to explain the methods now adopted: of course, there are variations of more or less extent in the modes of procedure peculiar to every foundry. The moulds, composed of a mixture of plaster of Paris and brick-dust, are made in the usual way on the plaster-cast models. A lining of wax or clay is then made within the mould, of the proposed thickness of the metal. The mould thus lined being then put carefully together, the space or interior is filled up solid with a mixture of plaster and brick-dust, &c.: this is called the core. The whole now consists of three parts—the mould, the lining of wax or clay (which represents the metal), and the core. When the mass forming the core is set, and fixed with irons and keys to preserve it in its just position, the mould is again taken to pieces, and the wax or clay removed; the channels for distributing the metal and vents for the escape of the air are then made, and the whole being put together is placed in a stove or oven to be dried. When perfectly free from any humidity (a most important point, as the slightest damp might occasion fatal consequences by the

bursting of the mould when the boiling metal descends into it), the whole is carefully lowered into the pit, and closely rammed down with sand, &c., to prevent its moving; the channels for the metal to enter and the vents for the escape of the air being of course kept perfectly clear. When the metal is ready for running, the mouth of the furnace, which is placed rather above the level of the top of the pit, is opened, and the bronze descends immediately into the mould. The mixture of metal preferred by the above-mentioned sculptor is that used for casting guns, to which he adds about 30 per cent. of pure copper, extracting from 3 to 4 per cent. of tin. In modern practice it is not, by many of the most successful founders, considered important to cast the whole work at once: on the contrary, in case of accidents, which however are of very rare occurrence, there is an advantage in being able to repair parts; and the process of burning, successfully adopted by Westmacott and others in the largest works (and which is found a great improvement on the ancient method of soldering), renders the joined portions even firmer or stronger at their point of junction than the general body of the cast. A description of the method of casting adopted in other foundries, differing somewhat from the above, will be found in the Introduction to Mr. D. Wyatt's 'Treatise on Metal work.'

This short history of bronze casting is purposely limited to its reference to the Fine Arts; and though, in speaking of celebrated productions or artists, it has been considered advisable to introduce incidentally such particulars of practice as might tend to illustrate the subject, the details of the various processes of moulding, coring, melting, chasing, &c., &c., are omitted, as belonging more properly to founding and casting. [FOUNDING.]

No particular reference has been made to the bronze weapons and ornaments of the ancient northern nations, as they could not properly be regarded as works of Fine Art, and they will be spoken of elsewhere. Here it will be sufficient to mention, that in the barrows and other sepulchral places of all, or nearly all, the northern races, bronze articles are found in great numbers, and of a kind to show considerable skill in the artificers. Most museums of antiquities contain numerous specimens; and by northern antiquaries the presence of bronze articles is regarded as a mark by which to assign the age of the person buried in the tomb,—the "bronze period" being one of their great divisions of "primeval antiquity."

The composition of different kinds of bronze will be found in the preceding article.

BRONZING; BRONZE POWDER. Much ingenuity is displayed in imitating the colour of ancient bronzes—both the greenish and the rich golden tints. Metals, wood, and plaster, are all subject to surface-processes having this object in view.

Captain Pidding states that the Chinese exercise the art of bronzing in a very superior manner. After having rubbed the vase or other ornament with coal-ashes and vinegar, they dry it in the sun, and then coat it with a composition, of which the following are the ingredients: two parts of verdigris, two of cinnabar, two of sal-ammoniac, two of the beak and liver of duck, and five of pounded alum: moistened to the consistency of a paste. When the article is thus prepared, it is passed through the fire, and washed when cold; again it is coated with the composition, again fired, and again washed; and so on for several times in succession.

Becquerel introduced to the notice of the Académie des Sciences, several years ago, a method of bronzing, in which a thin layer of bronze is applied to the surface of any article of iron, steel, lead, zinc, tin, or other metal. It is effected by precipitation from a solution, through the agency of a galvanic battery, in the usual manner of electro-metal-lurgy; but the difficulty to be surmounted consists in the discovery of a proper solution. The solution described by Becquerel consists of carbonate of potash, chloride of copper, sulphate of zinc, and nitrate of ammonia: with a plate of brass or bronze as a positive electro-decomposing plate.

A process of bronzing on paper is now frequently adopted for ornamental purposes. Thin plates of copper, or of copper alloyed with some other metal, are beaten out into thin leaves, and these leaves are ground or worked to powder. A pattern is printed on the surface of paper with an adhesive and rapidly-drying varnish; and just before this varnish is dry, the bronze powder is rubbed on with a piece of soft cotton, whereby a metallic lustre is produced, varying in its tint from a bright gold to a deep red colour, according to the metallic constituents of the bronze powder. Sheets of paper, thus bronzed after having been glazed and printed in various colours, now form highly adorned coverings for albums and many other kinds of books. In some of the recent novelties in colour-printing, this mode of bronzing is adopted as an adjunct.

BROWNING is a process applied to gun-barrels. Various liquids are used for this purpose, comprising two or more ingredients from a long list including aquafortis, spirits of nitre, blue vitriol, muriate of iron, butter of antimony, sweet oil, &c. The gun-barrel being well polished, and the oil removed by means of whiting, the browning solution is laid on, allowed to remain several hours, and then rubbed; these alternate processes are repeated two or more times. The barrel is afterwards cleansed with alkaline water, and polished. The natural colour of the wood-work, and the artificial tint imparted to the barrel, probably originated the designation of "Brown Bess," applied to the army musket.

BROWNISTS. [BROWN, ROBERT; in BIOG. DIV.]

BRUCIA BRUCINA, BRUCINE, called also "Vomicina." *Medical Uses of.*—The alkaloid above described exists in several species of *strychnos*, as well as in the bark of the false angostura; and as it is admitted on all hands that this bark is not obtained from any species of brucia, it has been proposed to change the name to *Caniramia* (derived from Caniram, and the name under which the *strychnos nux vomica* is described in Rheede, 'Hort. Malabaric,' vol. i. p. 67). The names are quite unobjectionable, as it exists in the *strychnos nux vomica* along with *strychnia*; but it is far from certain that the false angostura is the bark either of the *strychnos nux vomica* or of the *strychnos colubrina*, as conjectured by Virey. [GALIEPA.] It is most probably obtained from some undescribed South American species of *strychnos*.

Caniramin acts on the human system as a poison, and in precisely the same manner as *strychnia*, but more gently, being much less powerful. Hence it has been proposed to be substituted for it. The same precautions must be observed in its use, and the same contra-indications attended to. The cases in which it is most likely to prove useful are paralysis from lead, diarrhoea from atony of the intestines, and perhaps cholera asphyxia or Indian cholera. It is important to bear in mind that the anhydrous state of the salt is one-fifth more powerful than the crystallised. In case of poisoning, emetics may be given, and also tincture of bromine or iodine. [STRYCHNOS.]

BRUCINE. [NUX VOMICA, ALKALOIDS OF.]

BRUNOLIC ACID. This acid, the composition of which has not yet been determined, was found by Runge amongst the tarry products of the destructive distillation of coal. It is brown, vitreous, and easily reduced to powder.

BRUNSWICK GREEN. [GREEN.]

BRUSH; BRUSH-MAKING. The chief distinction in brushes is that between what may be called *simple* brushes, which consist of a single bundle or tuft of hair; and *compound* brushes, consisting of several small tufts, separately inserted in a handle. Of simple brushes, an illustration is afforded by the camels' hair pencil, the manufacture of which is described under PENCIL. These hair pencils are made of every variety of size, from the smallest pigeon or crow quill to the largest quills of the goose, turkey, or swan; and as even the largest quills are not large enough for some kinds of brush or pencil, while in other cases quills are not sufficiently strong and durable, tin tubes are occasionally substituted for them, the handle or pencil-stick being then firmly fixed in the tube. Even the smallest kinds of pencil made of bristles, or of the harder kinds of hair, for oil-painting, are usually mounted with tin, and are known by the general name of *tools*. For some purposes, tin mounted tools are made flat instead of round; the hairs being arranged in a flat, or chisel-like, instead of a cylindrical form. The larger kind of bristle tools are not inserted in tubes, but are bound round very tightly and tied to the end of a wooden stick or handle, which is cut into a forked shape, so as to have a projecting fin on each side of the bundle of hairs.

Other brushes have the handle inserted in the tuft. Among these are the large painting and dusting brushes used by house-painters, the bristles of which are first tied or wrapped round, with the smaller end of the conical wooden handle in their centre. The brush is then placed upon a block of iron perforated with holes to receive the handle, with the points of the bristles uppermost; and the conical handle is driven in with considerable force, until the greater part of its length has passed through the brush to form the handle, while the thicker end remains in the middle of the tied portion as a sort of core. Excepting in the peculiar mode of tightening the brush by the insertion of the handle, carpet-brooms and birch-brooms resemble, on a larger scale, this kind of brush.

Intermediate between the simple and compound brushes are white-wash and distemper brushes, which consist of two or more simple brushes placed side by side, and secured separately upon the edge of a flat handle.

Of compound brushes, which consist of numerous tufts or pencils of bristles or fibres, technically called *knots*, inserted separately in holes, the holes are bored in the stock, or back, by the aid of a lathe and borer. The mode of fixing the knots in 'pan-work' or 'set-work,' is as follows: The brushmaker arranges evenly a sufficient quantity of bristles to form a knot which will just enter one of the holes in the stock. Grasping these firmly, he dips the even end into a pan of melted pitch and tallow, then scrapes off the superfluous pitch, and afterwards takes a piece of strong thread called a *thrum*, and quickly binds it round the bristles. The end of the knot is then again dipped in the pitch, after which it is inserted in its proper hole in the stock with a peculiar twisting motion, which, coupled with the almost instantaneous setting of the pitch, renders it very firm and secure. In this way are manufactured long-brooms, bannister-brushes, hearth-brushes, and many other kinds of house-broom, and also many of the lighter kind of brushes, such as the dusting-brushes used for pictures and furniture.

In most of the brushes hitherto described, the bristles are used of their full length, or are very little cut; but in such brushes as are used for scrubbing or hard rubbing, the tufts are made short and cut at their ends to a square even surface, and the root ends of the bristles brought to the surface as much as possible. Clothes-brushes, and some

other brushes of this character, are occasionally made by the process last described.

Short and stiff-haired brushes are usually made by the 'drawn' method, instead of the 'set-work' method. The stock of a drawn brush is bored in a similar manner to that of a set brush, but more carefully. After each knot-hole has been bored just as far as the knot is intended to go, a smaller boring instrument, called a *bore-through-bit*, is fixed in the lathe, and with it a small hole is bored completely through the stock, in continuation of each knot-hole. The brush-maker then, instead of taking in his hand as many bristles as will fill the hole, takes about half that number, and passes a portion of their root-ends through the bight of a fine wire, which, with the other hand he has passed double through the stock from the small hole which penetrates it. Having done this, he gives a smart pull to the wire, the effect of which is to pull it back through the hole so far as the knot will allow it to come, the knot itself being, at the same time, drawn into a bight or double, which enters the hole in the stock, and is drawn in until stopped by the shoulder which is formed at the narrowing of the hole. Passing his wire, which is almost as pliable as thread, through the next hole, the workman applies another knot in like manner, and so on until a row is completed, when he cuts the ends of the whole row off with a pair of powerful shears, to which is attached by screws a gauge to regulate the precise length of tuft to be left. As the drawing-wires at the back of the stock would, if exposed, hurt the hand and be very liable to injury, it is usual to cover them, even in the commoner kinds of brushes, with a thin piece of wood as a veneer. Drawn brushes comprise all kinds of scrubbing-brushes, shoe-brushes, clothes-brushes, and tooth and nail-brushes. As veneering would be a difficult operation to perform upon tooth-brushes, these and other small brushes mounted in bone or ivory are frequently drawn with silver wire, which is either left visible, or sunk in fine grooves cut in the back of the brush, which are afterwards filled up with a hard red cement; but in the best sorts a very ingenious process called *trepanning* is substituted for the ordinary mode of drawing. In trepanned work the drawing holes are not continued through to the back of the stock, but are formed laterally in its thickness, from the end or sides, in such a way that after the drawing, which is then performed with thread or silk instead of wire, is completed, all traces of the operation can be concealed by filling up a few minute holes in an unobtrusive part of the stock with small plugs of bone or ivory.

The operation of drawing, in the larger and coarser kinds of work, requires great strength of hand and arm, and is performed by men. In the finer kinds of brush-drawing, in washing and picking the bristles, and in various operations connected with the manufacture of fancy brushes, women are extensively employed; and as the manufacture is one usually conducted upon rather a small scale, so as to partake of the character of a private or domestic manufacture, it appears to be well adapted for the employment of females and children.

There are a few other kinds of brush, such as bottle-brushes (consisting of tufts fixed so as to radiate from a stem of twisted wire), which it is needless here to particularise. Dr. Ure described a mode of fixing the knots or tufts of brushes in dovetailed grooves formed in the stock, which was the subject of a patent granted in 1830 to Mr. Mason. More recently a patent has been obtained by Mr. Hancock for the manufacture of flexible back brushes, in which the knots are attached to yielding backs of leather instead of wooden stocks, and for some purposes such brushes seem to possess considerable advantages over those of the common construction.

Of the materials employed in the brush manufacture the most important are hogs' bristles. [BRISTLES.]

An ornamental appearance is often produced by the insertion, in one brush, of knots of picked bristles of various colours; and it is a common practice to put white or yellow bristles at the outside of a brush intended to look neat, while the centre is filled with those of a dark colour. For very soft brushes, such as hat-brushes, horse-hair, goats'-hair, and other kinds of hair are used; and for purposes which require unusual stiffness, fibres of whalebone, either alone or mixed with bristles, are sometimes employed; but the present high price of whalebone restricts its use. For very coarse brooms, for stable and out-door use, a hard and tough dark-coloured vegetable fibre called *bass* is much used: brooms made of it superseding, in a great measure, those of birch or heath. *Wisk* is a light-coloured vegetable substance of much finer quality, used principally for carpet brooms; and a very fine article of the same character has been recently employed in making brushes for velvet. The woods chiefly used for the stocks of the common kinds of drawn brushes are beech and oak, and among those employed in ornamental articles are sycamore, lime, rosewood, and satinwood. For brooms, in which lightness is desirable, alder and birch are much used. The wire employed for drawing is mostly a peculiar kind of brass wire made for the purpose, copper having been found too brittle; but a very superior article of compound metal, which has much the appearance of copper, but is very strong in proportion to its extreme tenuity, and soft and pliable to a degree which appears surprising in any metal, has recently been introduced under the name of red brass wire.

Mr. Cole, a brush-manufacturer, took out a patent in 1842 for numerous improvements in brush-making. In the general modes of making brushes the bristles are fixed in their places either by some

kind of cement or by wire; but in Mr. Cole's method the knot of bristles is kept in each hole by the hole being made of a conical shape, with the smaller end of the cone at the face or hair side of the brush: the knot is so shaped that it maintains its place in the brush without either cement or wire. A second improvement consists in steeping in a preservative solution the string with which some brushes are bound round, so as to enable them to be placed in water without loosening. A third consists in a new mode of fastening wedge-shaped handles into various kinds of brushes. A fourth consists in the manufacture of a new kind of brush for delicate purposes, by making a covering of plush to a foundation of white flock. A fifth consists in making brushes or pencils of spun glass, by which aquafortis and other corrosive acids can be applied by silversmiths and jewellers with more delicacy and safety than by any of the usual means. A sixth improvement is in the construction of brushes intended for cleansing decanters and bottles. A seventh relates to brushes for cleaning cruets and small phials.

Numerous patents appear from time to time, relating to new forms of brush. Some are ingenious and useful; others are singular, without any great chance of being useful. One patent relates to a project for making brushes and brooms of the branches of the cabbage palmetto tree, in such a way that the handle shall form one piece with the brush. Another is for a mode of setting the bristles of an ordinary brush diagonally, by which arrangement, more of them are brought into action at once, and the surface of the brush is firmer. A third is a boiler-cleaning brush: the brush, by the aid of certain wedges, is made to expand and contract, so as to suit the diameters of different kinds of boiler-flues. A fourth is a boot- and shoe-cleaning machine, comprising two discs having brushes on their edges; treddles give motion to the discs, and the boot or shoe is simply held against the brushes. Many of the forms of knife-cleaning machines consist mainly of two sets of brushes revolving in contact, or nearly so; and the revolution being in opposite directions, great friction is brought to bear on the two surfaces of the blade of a knife thrust between the brushes. One of the oddest of these novelties is a mode of applying galvanic treatment to the hair, by brushes, of which some of the hairs (if they can so be called) are copper wire, and others zinc wire; a roll of flannel damped with some acid is to be enclosed in the wood-work of the brush, in such a way as to communicate moisture to the discs; and the theory of the inventor seems to be that galvanic action, useful in certain states of health or unhealth, would be produced by brushing the hair with a brush so constructed.

BRYOIDIN. A crystallisable substance, found in the resin of the *Canarium album*. It separates from a watery solution in fine silky filaments, which fuse at 275° Fahr., and volatilise slowly at the same temperature. Bryoidin is slightly soluble in cold, more so in hot water, and very soluble in alcohol and ether. Its solution is without action on turmeric paper, but it precipitates solution of acetate of lead.

BRYONIN. The peculiar principle of bryony-root to which the peculiar properties of the latter are owing; it is a yellowish white substance, sometimes with a red or brownish tint; its taste is at first rather sweet, then styptic and extremely bitter. It is soluble in water and in alcohol, but insoluble in ether; chlorine does not decompose it; sulphuric acid dissolves it, acquiring first a blue and afterwards a green colour. When decomposed by heat it yields ammonia (?). Alkalies do not alter it; the aqueous solution is precipitated white by nitrate of silver, yellow by chloride of gold, and white by protonitrate of mercury and by diacetate of lead; tincture of galls precipitates it of a bright gray colour. It is a drastic purgative, and poisonous in too large doses.

BUCCANEERS, a most numerous and well-known association of sea-robbers or pirates, who were also called 'The Brethren of the Coast,' and still more commonly 'Flibustiers.' The term *Buccaneer* is of curious derivation. The Caribbee Indians taught the colonists in the West Indies a singular mode of curing and preserving the flesh of cattle: when cured, this flesh was called *Boucan* by the Caribbees: from *boucan* the French made the verb *boucaner*, which the 'Dictionnaire de Trevoux' explains to be "to dry red, without salt." Hence comes the noun *Boucanier*, and our *Buccaneer*.

The term *Flibustier* is supposed to be nothing but the French sailors' corruption of our word 'freebooter;' and it is a curious fact, that as we always used a word corrupted from them, so the French designated the robbers by a word derived from us, invariably calling them *flibustiers*, or *freebooters*. The Americans of the United States have farther modified the word into *flibuster*, and use it to designate those who undertake wars against foreign countries without the sanction of the state.

The *Buccaneers* were natives of different parts of Europe, but chiefly of Great Britain and France. They were most of them seafaring people, and the origin of the associations about the year 1524 was entirely owing to the jealousy of the Spaniards, who would not allow any other nation to trade or settle in the West Indies, and who pursued the English or French like wild beasts, murdering them wherever they found them. At that time and long afterwards, Spain, in right of her priority of discovery, and of the well-known bull of Pope Alexander VI., considered the whole of the New World as treasure-trove of which she was lawfully and exclusively the mistress. Every

foreigner found among the islands or on the coasts of the vast American continent was treated as a smuggler and robber, and this being the case it is no wonder that seafaring adventurers soon became so, and returned cruelty by cruelty. As early as 1517, when an English ship appeared at St. Domingo to request liberty to trade, the Spaniards fired their cannon at her and drove her away. When this unexpected visit was reported to the Spanish government at home, the minister sent out a sharp reprimand to the governor of St. Domingo because he had not artfully seized the ship instead of driving her away, and so disposed of the English that no one of them should have returned to teach others of their nation the route to the Spanish Indies. But the enterprising nations of Europe were not to be checked by the tyranny of Spain, nor could a papal bull shut the eyes of navigators and make them blind to the improving science of navigation, or to their way across the ocean. The mariners of Europe, moreover, still considered the New World as an Eldorado where gold and treasure were to be had for the fetching, and this made them brave the monstrous cruelties of the Spaniards. In 1526 one Thomas Tyson was sent to the West Indies as factor to some English merchants, and many adventurers soon followed him. The French began to make voyages to Brazil, and the Portuguese and the Dutch successively began to show themselves in numbers in the West Indies. Knowing what they had to expect they were always prepared to fight desperately. From an ingenious phrase, '*se dédommager d'avance*,' used by one of the French filibusters, it appears they did not always wait to be attacked, but in case of a favourable opportunity became themselves the assailants. To repress these interlopers the Spaniards employed *guarda-costas*, the commanders of which were instructed to massacre all their prisoners. This tended to produce a close alliance, offensive and defensive, among the mariners of all other nations, who in their turn made descents on the coasts, and ravaged the weaker Spanish towns and settlements. A permanent state of hostilities was thus established in the West Indies entirely independent of peace or war at home. 'The Brethren of the Coast' cared not if their respective native countries in the Old World were at peace with Spain; in the New they must of necessity fight the Spaniards or die, or relinquish the benefits which that immense region offered. When not engaged in traffic with the Indians or in predatory excursions against the Spaniards, the principal occupation of these men was hunting wild cattle, of which they made their *boucan*, but they did not begin the latter occupation until several years after their first appearance in the Caribbean seas. At a still later date many of them became logwood cutters in the bay of Campeachy, and as both these occupations soon became very profitable, and trading ships from Europe began to resort to them in numbers for their hides, suet, dried meat, wood, &c., there is good reason for supposing that if the Spaniards had left them in peace they would gradually have settled down into quiet industrious communities. But instead of this, the Spaniards continued to murder them whenever they could surprise them, to burn their log-huts, to hunt them from place to place, and even to kill the shipwrecked mariners who were thrown by misfortune upon their coasts. The effect of all this was, that the buccaneers became as sanguinary as their enemies, increased their numbers, condensed their operations, and soon considered everything Spanish as fair prize, and every Spaniard's life a forfeit to them. Some home-returning filibusters brought accounts of the barbarities of the Spaniards into Europe, where they soon got into print, were circulated as popular stories, and produced an immense sensation. A Frenchman of the name of Montbars on reading one of these stories conceived such a deadly hatred of the Spaniards that he became a buccaneer, and killed so many of that nation in the West Indies that he obtained the title of 'The Exterminator.' Other men joined the brethren of the coast from less ferocious motives. Raveneau de Lussan took up the trade of buccaneering and robbing because he was in debt, and wished, as every *honest man* should do, to have wherewithal to pay his creditors. By degrees many men of respectable birth joined the associations, on which it was customary for them to drop their family name and assume a new one. Some of the buccaneers were of a religious temperament. A French captain, named Daniel, shot one of his crew in church for behaving irreverently during the celebration of mass. Captain Richard Sawkins, an Englishman, threw the dice overboard on finding them in use on the Sunday; and the first thing Captain John Watling did was to order his robbers to keep holy the Sabbath.

In 1625 the English and French conjointly took possession of the island of St. Christopher, and five years later of Tortuga, which islands became the head-quarters of the buccaneers, who, whenever the countries of which they were natives were at war with Spain, obtained commissions or letters of mark from Europe, and acted as regular privateers in the West Indies and on the Spanish Main. This latter custom gave a colour of legitimacy and honour to their calling, and confounded the notions of right and wrong in their ignorant minds. The governors of the first English colonies in the West Indies, or at least the majority of them, were great rogues, and on condition of sharing spoils with the buccaneers they let them do pretty much as they chose, even when there was no war with Spain.

In 1638 the Spaniards in force surprised Tortuga, while most of the adventurers were absent in Hispaniola hunting cattle, and they massacred all the English and French buccaneers that fell into their hands. The buccaneers soon retook the island, and made it the centre of their

hunting and cruising as before. These singular associations were held together by a very simple code of laws. It is said that every member of it had his chosen and declared chum or comrade, between whom and himself property was held in common while they lived together, and when either of the two died the survivor succeeded to whatever he possessed; but as buccaneers were known at times to bequeath property by will to their friends in Europe, this cannot have been a compulsory regulation. What, however, was insisted upon by their corporate laws was, that there should be a general participation in certain essentials, among which were enumerated meat for present consumption and other necessities of life. It has been said that bolts, locks, and all kinds of fastenings were prohibited among them, as implying a doubt of the "honour of their vocation."

In addition to the names already mentioned, Peter of Dieppe, called "Peter the Great," Bartolomeo Portuguese, François L'Olonnais, and Mansvelt were distinguished captains of buccaneers, who made themselves terrible in those seas. But the fame of all these men was eclipsed by Henry Morgan, a Welshman, who succeeded Mansvelt in a sort of general command. He took and plundered the town of Puerto del Principe in Cuba, attacked Puerto Bello, one of the best fortified places in that part of the world, and took and sacked Maracaibo and Gibraltar. Morgan displayed not only the greatest bravery, but many of the higher qualities of a commander; like most of his predecessors, however, he was treacherous, cruel, and bloodthirsty. He was in the habit of torturing his prisoners in order to make them confess where they had concealed their treasures. The boldest and most astonishing of all Henry Morgan's exploits was his forcing his way across the isthmus of Darien from the Atlantic to the Pacific ocean. His object was merely to plunder the rich city of Panama, but his expedition opened the way to the great southern seas, where the buccaneers soon achieved strange exploits, and laid the foundation of much of our geographical knowledge of that ocean. In December, 1670, thirty-seven vessels, having on board about 2000 men, rendezvoused at Cape Tiburon under the enterprising Welshman, whom French and English obeyed with equal alacrity. On the 16th of December he took the island of Santa Catalina, where he left a strong garrison. He next took the strong castle of San Lorenzo, at the mouth of the river Chagre, on the east side of the isthmus of Darien, where out of 314 Spaniards he put 200 to death. He left 500 men in the castle, 150 to take care of his ships, and with the rest, who, after deducting the killed and wounded, amounted to about 1200 men, he began his land march through one of the wildest and most difficult countries, which was then only known to the wild Indians. The fatigues and difficulties they suffered on this march were dreadful. On the tenth day after his departure from San Lorenzo, Morgan, after a desperate combat with the Spaniards, who had 2000 foot and 400 horse, took and plundered the rich city of Panama, which then counted about 7000 houses. Here again his cruelties were abominable. He returned in safety, and loaded with wealth, to San Lorenzo, where he found all his ships undisturbed. Having tricked most of the fleet out of their share of the spoils, he sailed for Jamaica, which was already an English colony. This dexterous ruffian was afterwards knighted by Charles II., and became successively commissioner of the admiralty court in Jamaica, and deputy governor of that island.

In 1673 the Spaniards murdered 300 French filibusters, who had been shipwrecked at Puerto Rico—a barbarous act which provoked atrocious reprisals.

The short way to the South Seas had been shown by Morgan, and, in 1680, about 330 English buccaneers started from the shores of the Atlantic to cross the Isthmus. The route they pursued varied slightly from that followed by Morgan; but they had men with them more capable of describing what they saw. These were Basil Ringrove, Barty Sharp, William Dampier, and Lionel Wafer, each of whom, in after years, wrote and published an account of his adventures, with a description of the country. Although they formed an alliance with the Darien Indians, who hated the Spaniards, this expedition was not in sufficient force to attack Panama. Two hundred of them, however, having procured a number of small Indian canoes, launched into the bay of Panama, attacked three large armed ships, took two of them, and began cruising in them. These fellows had even some diplomatic skill. Ringrove tells us that the governor of Panama sent to demand of Sawkins their captain, "Why, during a time of peace between England and Spain, Englishmen should come into those seas to commit injury? and from whom they received their commission?" Sawkins replied, "That he and his companions came to assist their friend the king of Darien, who was the rightful lord of Panama, and all the country thereabouts." They then proceeded to capture ships and plunder the towns along the coast, and some of them remained a long time in the South Seas, and made many discoveries.

In 1684 another expedition, in which also the skilful seaman Dampier and the surgeon Wafer were engaged, sailed from Virginia, and, stretching along the whole of South America, doubled Cape Horn and entered the South Seas to plunder the Spaniards. Many of these hardy adventurers explored the Pacific, from the coasts of Chili, Peru, Mexico, and California, to the shores of China, Malacca, and India; and we scarcely know anything of the sort so interesting as Dampier's narrative of this expedition.

In 1670 a solemn treaty of peace, known in diplomacy by the name

of the "Treaty of America," which provided for the entire suppression of the buccaneer warfare, was concluded between Great Britain and Spain; but, as far as the buccaneers were concerned, this was a bit of waste paper, for much the most daring of their achievements took place after the date of the treaty.

The war between Great Britain and France, which followed the accession of William III., in 1688, did much more to relieve the Spaniards from the scourge. The French, without waiting for a declaration of war, attacked the English in the West Indies, where, for some time, the chief belligerents were those ancient allies and comrades, the filibusters of one nation and the buccaneers of the other, who were now called privateers, and duly commissioned. The bonds of amity were broken; they exercised upon each other some of the cruelties they had exercised in common upon the Spaniards, and they never again confederated in any buccaneer cause. At one time, had they been properly headed, and had conquest, not plunder, been their object, they might, by degrees, have obtained possession of a fair portion of the West Indies—they might perhaps have established an independent state among the islands of the Pacific. Henry Morgan, in fact, at one time entertained this magnificent idea.

The treaty of Ryswick, in 1697, and four years later the accession of a French Bourbon prince to the throne of Spain, brought about the final suppression of the buccaneers. Many of them turned planters or negro drivers, or followed their calling as sailors on board of quiet merchant vessels; but others, who had clippers, or good sailing ships, quitted the West Indies, and went cruising to different parts of the world. For nearly two centuries their distinctive character or function had been the constant waging of war against the Spaniards, and against them alone, and now this was lost for ever.

"After the suppression of the buccaneers," says Captain Burnet, "and partly from their relics, arose a race of pirates of a more desperate cast, so rendered by the increased danger of their occupation, who for a number of years preyed upon the commerce of all nations, till they were hunted down, and, it may be said, exterminated."

(*History of the Buccaneers of America*, by James Burney, F.R.S.; *Lives of Banditti and Robbers*, by C. Mac Farlane; *The Buccaneers of America*, by an old anonymous author; *Dampier's Voyages*; Lionel Wafer's, Basil Ringrove's, and Barty Sharp's *Narratives*; and, in French, the works of Père Charlevoix.)

BUCCINA, a military instrument of the shrill horn, or cornet, kind, in use among the ancients, and by some supposed to have been formed of the horn of the bull or goat. According to others it was the shell of the buccinum, a fish. Vegetius ('De Re Militari') says that it was made of brass, and bent in a circle. Blanchinus ('De Instrum. Vet.') also states that it was a metallic instrument; but from the engraving he gives of it, after ancient bas-reliefs, &c., the buccina would appear to have been perfectly straight. Sir John Hawkins coincides in opinion with Blanchinus, and copies the form of the instrument from a plate given in the work of the learned Italian; Burnet ('Hist. of Music') gives an engraving of a curved buccina with a very wide mouth. The buccina in its primitive state was probably a simple horn, and was subsequently formed of a more durable material. Ovid ('Met.' i. 335) gives an excellent description of the buccina.

BUCENTAUR (IL BUCENTO'RO), the state-galley of the republic of Venice, for the name of which many very unsatisfactory derivations have been proposed.

The most elaborate description of this gorgeous vessel with which we are acquainted is that given in the 'Chronica Veneta.' But we doubt not that the reader will gladly be spared a minute account of the carving and gilding with which it was adorned; and a detail of the marine deities, the sirens, the masques, the fruit, the flowers, the shell-work, the medallions, the cornucopias, the allegorical groups, the winged lions, the birds, the zodiacs, the canopies, the virtues, and the liberal arts, which were profusely scattered over it on one of its latest repairs by the skill and taste of 'Giovanni Adami, Doratore Veneto.'

It may be sufficient to state that it was 100 feet by 21 in extreme length and breadth; 168 rowers, four to each oar, were allotted to it from the arsenal, and were disposed in a lower deck; besides these it was manned by a crew of 40 mariners. The upper deck was covered with an awning (*tiemo*) of crimson velvet, beneath which were seated the doge and his goodly company. The doge himself was enthroned near the stern, surrounded with foreign ambassadors, and the senators and great officers of state were disposed on seats running in four rows along the length of the vessel.

The date of the original Bucentaur is not very clearly ascertained; but, like the famous ship at Athens, although in perpetual flux, the galley of the moment, according to Howell, was ever reputed "to be the self-same vessel still, however often put upon the careen and trimmed." "Yet I believe there is not a foot of that timber remaining which it had upon the first dock, having been, as they tell me, so often planked, ribbed, caulked, and pieced." Its use on the feast of Ascension is traced to a victory obtained in the year 1177 by the Doge Sebastiano Ziani over the Emperor Frederic Barbarossa. The Venetians had espoused the cause of Pope Alexander III., who had taken refuge in the Lagune. The doge, with a fleet not mustering half the number of vessels which Pisa, Genoa, and Ancona had placed under the command of the Emperor's son Otho, encountered them off the coast of

Istria. After a battle which lasted more than six hours, Otho, with 48 out of his 65 galleys, was taken prisoner, two of his ships having been destroyed. The pope received the conquerors on the Lido, and presenting Ziani with a golden ring addressed him in these words: "Take this ring, and with it take, on my authority, the sea as your subject. Every year, on the return of this happy day, you and your successors shall make known to all posterity that the right of conquest has subjugated the Adriatic to Venice as a spouse to her husband." The Venetians themselves have sometimes claimed an earlier authority for this lordship of the Adriatic; and Foscarini ('Della Letteratura Veneziana,' lib. ii.) finds some trace of it in Dandolo's 'Chronicle' towards the close of the 10th century.

The Bucentaur having been conducted, on the eve of the feast of Ascension, from the arsenal to the piazza, received its splendid passengers. Accompanied by innumerable feluccas and gondolas, it passed on to the mouth of the Lido amid the thunder of artillery. On coming in front of the chapel of the arsenal, the rowers in maritime fashion, saluted an image of the Virgin, and in the meantime the patriarch of Santa Helena, on which island is a convent, awaiting the pomp, was entertained by the monks with a repast of chestnuts and water (*una veramente religiosa, povera colazione*). As soon as the doge appeared in sight, the patriarch embarked with his clerical suite in a small gilded barge (*peatone*) in order to meet the procession, and during his passage he blessed the remainder of the water, which was afterwards thrown into the sea. On issuing from the port of Lido, near the mouth of the harbour, the doge dropped a ring into the bosom of the Adriatic, betrothing her by these words, "We wed thee with this ring in token of our true and perpetual sovereignty." He then returned to the church of San Nicolo di Lido, and having heard a solemn pontifical mass, re-embarked in the Bucentaur and entertained his cortège with a magnificent banquet in the palace.

When the French took Venice, the original Bucentaur was burnt. It was replaced by a model made from drawings and from the recollections of the workmen; this was deposited in the arsenal, but has ceased to be an object of any interest.

BUCHU, or BOOCHO. *Medical Properties of.* These are names given by the Hottentots to the leaves of several species of evergreen shrubs, natives of South Africa, referred by botanists to a species of one of the genera formed out of the old genus Diosma. The several species yielding buchu belong to the genus Barosma, or Baryosma, a more appropriate name than Diosma, many having to Europeans anything but a *divine* fragrance. Three species chiefly are collected. *B. crenata* (Ecklon), *B. crenulata*, Willd., *B. serrata*, Willd. The differences of these are slight, being only of shape and size; they have all one general character, more or less oblong, nearly an inch long by a quarter broad, more or less serrated or crenated at the edges, of a pale or yellowish-green, thickly studded with deeply imbedded transparent glands, filled with volatile oil, and which gives to the dried coriaceous leaves a puckered appearance. On bruising the leaves, the peculiar odour is very perceptible. This is likened to rosemary by those who relish it—to rue, cumin, or cat's urine by those who do not like it. The taste is warm, pungent, mint-like.

The chemical analyses by Cadet de Gassicourt, and in the same year by Brandis, closely correspond. No alkaloid was found, but volatile oil 0.665, gum 21.170, extractive 5.170, chlorophyll 1.100, resin 2.151, lignin 69.744, from Barosma crenata. The bitter extractive has been deemed by Brandis peculiar, and called Diosmin. The volatile oil is yellowish brown, and lighter than water. To it the peculiar odour of buchu is due, as well as much of the medical virtue of the plant.

The Hottentots use a powder obtained by bruising the leaves of several species, and mixed with lard, to besmear their bodies; they distil a kind of brandy (Buchu brandy) from the leaves, along with the dregs of wine. An infusion is also used by them.

The bitter extractive and volatile oil possess tonic, stimulant, and some astringent properties; the organs of secretion feel these, as well as the nervous powers. The digestive organs are strengthened, but the urinary organs feel the influence most. A feeble condition of these with excessive secretion, is much benefited. The skin, in some chronic affections of a gouty or rheumatic origin, is improved. But no disease is so certainly influenced by buchu as the rheumatism which attacks Europeans on their return to a cold climate, after a residence in hot climates, particularly Africa. The spasms of the chest or heart connected with rheumatic irritation of these organs are much relieved by buchu. Asiatic cholera is stated to have yielded to it; but in the bad cases, like everything else, it failed. The best form is infusion with cold water, or tincture. The wine is not so good—while hot water employed to make an infusion dissipates the volatile oil on which its activity should depend.

BUCKTHORN (*Rhamnus catharticus*, or *Spina cervina*), *Medical uses of.*—The berries contain a peculiar extractive, a colouring principle, acetic acid, gum, and sugar, which is of the nature of grape sugar. The properties are purgative, and the action is attended with much sickness, griping, and thirst. All the forms of exhibition are objectionable, but particularly the berries, either fresh or dried: yet this acrid and almost poisonous article is retained in practice, and is a common domestic medicine, especially for young children, the most unsuitable of all for its employment.

The berries of several different shrubs are said to be substituted for those of the *R. catharticus*; a circumstance which is fortunate, if any more harmless are made to replace them. Buckthorn berries are themselves used to adulterate cubebs.

BUCK-WHEAT (*Polygonum fagopyrum*) is said to be found wild in Persia. The cultivation of it, according to some authorities, was introduced into Europe by the crusaders; according to others, the Moors introduced it into Spain from Africa; and hence it has in France the name *blé sarrasin*. The name of buck-wheat is a corruption of the German buch-weizen, which signifies beech-wheat, from the resemblance of the seed to that of the beech-tree. It is called wheat because, when ground, it produces a fine farina, which resembles that of wheat in appearance. The botanical name of the genus, *Polygonum*, is taken from the angular form of the seed, and the specific name, *fagopyrum*, from its resemblance to beech-mast. Buck-wheat grows with a strong herbaceous, cylindrical, and branching stem of a reddish colour, about 2 feet high. The leaves, which are ivy-shaped, are placed alternately on the stems. The flowers grow in bunches at the end of the branches, and are succeeded by black angular seeds, formed of four triangles, being thus nearly regular tetrahedrons. The plant is an annual, and the flowers appear very soon after it is out of the ground. They continue to blow and bear seed in succession till the frost destroys the plant. Being a native of a warm climate, the smallest appearance of frost in spring, while the plant is tender, entirely destroys it. Hence it is never sown in northern climates till all danger of frost is over, which in many parts of England is not till the middle of May; but its growth is so rapid, that it may be reaped in September, at which time the principal part of the blossoms will have ripened their seeds. No advantage would be gained by leaving it longer on the ground, for even if the frost did not kill the whole plant, the earliest ripened seeds would be shed and lost; and the last blossoms would not produce perfect seeds.

The cultivation of buck-wheat has never been very extensive in the variable climate of Britain. It is not so well adapted to cold wet soils as to warm sands; nor is it so certain a crop as oats or barley on lands which are suited to the growth of these grains. For countries where there are very poor light lands with a hot dry climate, unfavourable to the growth of oats, and not rich enough for barley, buck-wheat is a great resource; and without it, many tracts of poor land would scarcely be capable of supporting a population. As a principal crop, therefore, it is confined to some parts of the south of France and other countries similar in soil and situation. As a secondary and occasional crop, it often occurs in Switzerland, Germany, and especially in Flanders, where it enters as a regular part of their varied and complicated rotations. Under particular circumstances, it might be introduced with advantage into many parts of England where it is now unknown. The only counties in which it is cultivated to a moderate extent at present are Norfolk and Suffolk, where it is called *brank*. If a small patch of buck-wheat is occasionally met with elsewhere, it is, in general, mainly for the sake of encouraging game, particularly pheasants, which are extremely fond of it.

When buck-wheat is cultivated as a regular part of a rotation, it is generally after the land has been considerably exhausted by former grain crops, and manure cannot be had in sufficient abundance to recruit it. It will then produce a better return than oats, and leave the land in a better state, especially in warm and dry seasons. On richer and better soils it may be occasionally a good substitute for barley, when the land cannot be properly cleaned and tilled sufficiently early in spring; for it allows a full month more to prepare the ground; and in this one month, if it be hot and dry, a good tillage may produce nearly all the advantage of a summer fallow. Buck-wheat, on good land, will produce nearly as valuable a crop as barley, though it is certainly more precarious; the seeds sown with it will probably produce more grass or clover than they would if sown with barley; for buck-wheat, sown thin, as it always should be in this case, does not choke the grass, but shelters it from the scorching rays of the sun; and as it draws the land less than any other grain, it leaves it in better heart for the clover. It has been strongly recommended to be sown on good, clean, light land, after winter tares have been either fed off by sheep or cut green for horses. By this means, the root weeds, which had been smothered by the tares and ploughed up immediately after the tares were off, will not have time to spring up again; the rapid growth and the shade of the buck-wheat effectually keep them down, and prevent the annual weeds from going to seed. Thus a crop is obtained between the tares and the wheat, and the land is kept perfectly clean. This is mentioned by Arthur Young, in the 'Survey of Suffolk,' as a successful practice, and strongly recommended. Buck-wheat may be ploughed into the ground in a green state. For this purpose, it is sown tolerably thick, and when the plant is in its greatest vigour and in full blossom, a roller is passed over the crop to lay it level with the ground. The plough, with the addition of a skim coulter, turns it neatly into the furrows and completely buries it. It soon decays from its own moisture, and the decomposed parts being incorporated with the soil greatly add to its fertility.

On poor sandy reclaimed soils, especially if they are trenched to a considerable depth, buck-wheat may be sown with great advantage for the purpose of being ploughed in as a preparation for the first crop of turnips. The turnips fed off by sheep penned on them will enrich and

consolidate the ground sufficiently for a crop of corn or clover and grass seeds. A bushel and a half, or at most two bushels, is an ample allowance of seed for an acre; the cost of it is at most 8s. or 10s. When buck-wheat is ploughed in for manure, care must be taken to consolidate the surface of the land, if it be light, by rolling or other means, for the decaying stems leave it very loose and hollow; but if the soil is tenacious, the air which is let in mellows it and makes it crumble, which is a great advantage. Provided the soil be stirred to a considerable depth, so that the roots of the buck-wheat may strike deep in search of nourishment, however poor or light it may be, or however dry the weather, it will produce a good crop of seed. It only wants a few showers at first, and at the time when the seeds begin to be formed. It continues to put forth blossoms for a long time, and if the first-formed seeds should not be so full as might be wished, the latter may probably make up for it. The careful husbandman must examine the plants at different periods, and reap when he finds the greatest quantity of ripe and full seeds. It is not possible by any management to have all the flowers come to seed in perfection; but under favourable circumstances from four to five quarters of good seed may be obtained from an acre of well-tilled land.

Manure is seldom or never laid upon land upon which buck-wheat is sown, because even where manure is abundant it is reserved for other crops supposed to require it more. It is asserted by many that manure makes the buck-wheat run to haulm and diminishes the crop of seed. That this may be the case with injudicious additions of dung, we are not inclined to dispute; but if the land be tilled to a sufficient depth, if the manure be well prepared and intimately mixed with the soil, and if the buck-wheat be sown thin in proportion to the richness of the land, we have no doubt that it will not only grow high and strong and blossom well, but also give an abundant crop of seeds. The reason why crops run to straw and are deficient in corn, when the land is moist and has been highly manured, is, that the manure ploughed in and covered only with a few inches of soil excites an extraordinary vegetation in the young green plant, which makes it shoot out a strong vigorous stem; but by the time of flowering, the dry weather has exhausted the rich moisture of the manure, and the plant, pushing its roots downwards in search of food, finds a less fertile soil below, out of which it cannot draw the materials to form a full and plump seed. But when a soil is naturally rich, or artificially made so to a considerable depth, a strong and high stem is generally the forerunner of a great bulk of seed, as is often seen in those oats which are scattered thinly among winter tares, the straws of which are like reeds, and the grain, if allowed to ripen, is always both heavy and abundant.

Buck-wheat is sometimes cut in its tender state for soiling cattle. It is said to increase the milk of cows greatly: it is also occasionally pastured by sheep. There is a diversity of opinion on its qualities, some speaking highly of it, and others asserting, and with some appearance of truth, that it is not eaten by sheep or cattle in preference to any other plant, and that it has a stupifying and intoxicating effect when eaten in any great quantity. Upon the whole, we are inclined to think that its value is chiefly as an addition to the variety of plants cultivated for their seeds, and as a cheap vegetable manure.

Buck-wheat may be reaped with the sickle or mown with the scythe, or it may be pulled up by the roots. The latter method is recommended by some, as less likely to shed the seed when fully ripe. In dry weather it is recommended to cut or pull it very early in the morning or late at night, when the dew is on it, and not to move it much in the day. It may be tied up in sheaves, or put into small heaps, as is done with peas. In either case birds must be carefully scared away, or they will take a large share of the produce.

Buck-wheat as a grain may be given to horses instead of oats, or mixed with them. No grain seems so eagerly eaten by poultry, or makes them lay eggs so soon and so abundantly. The meal, when it is ground, is excellent for fattening cattle or pigs. The flour is fine and white, but from a deficiency in gluten does not make good fermented bread. It serves well, however, for pastry and cakes: crumpets made of buck-wheat flour eaten with butter are a favourite dainty for children in Holland. A hasty pudding is also made of the flour, with water or milk, and eaten with butter or sugar.

On a careful consideration of the reasons for and against a more general cultivation of buck-wheat in our northern climates, it appears to have certain qualities which make it well worth attention. As it belongs to a different natural family in the vegetable kingdom, it is probable that it may be a useful change when the land has been too long cropped with gramineous plants. It may impart to the soil, or abstract from it, some principles by which its power of producing other crops may be increased. This can only be learned with certainty by repeated experiments; but some considerable effect may be expected from the powerful salts which we know are found in the ashes. Its value as a manure is indisputable; the only thing required is an accurate calculation of the comparative expense of its application with that of bones or any other purchased manure, taking quality and quantity into consideration. A few experiments on an extensive scale, and made with that attention to minute circumstances which is so often neglected in agricultural experiments, and repeated with perseverance, might place the cultivation of buck-wheat in a new point of view.

An analysis by Horsford, given in Morton's 'Cyclopædia of Agriculture,' gives the following as the composition of the seed :—

Organic matter fitted for the formation of flesh	8.58
Matter fitted for respiration, &c.	51.91
{ Starch	23.12
{ Fibre	2.20
Ashes	14.19
Water	100.

The ash, as analysed by Sprengel, contains

Potash	10.27
Lime	21.98
Magnesia	40.34
Alumina (?)	0.81
Silica	4.37
Peroxide of iron	0.47
Peroxide of manganese	1.00
Chloride of sodium	4.90
Sulphuric acid	6.77
Phosphoric acid	9.00
	100.00

These results will no doubt vary according to the soil in which the plants have grown. The potash is so abundant that it has been suggested as a profitable use of the haulm to burn it for the purpose of obtaining this useful salt. This abstraction from the soil, or its addition to it in the shape of manure, must produce a considerable effect on the fertility. There is another species of buck-wheat mentioned by some authors as superior to the common, and more deserving of culture in northern climates; it is called the *Polygonum Tartaricum*. Yvart, in his excellent article, 'Succession de Culture,' in the 'Cours Complet d'Agriculture,' Paris, 1820, speaks highly of the Tartarian buck-wheat. It is yellower in the colour, and bears a smaller seed, but is much harder. Its stubble will remain alive during the winter, grow out in spring, and produce a second crop the next year if let alone; but this does not seem any great advantage, as the second crop is very apt to be overrun with weeds. Yvart mentions a crop grown in the Department de l'Isère which appears extraordinary: 12 measures sown produced 1296 measures, or more than a hundredfold, in a very dry season. Another gentleman obtained 80 for one. After all, experiments reported in this way teach very little: a return so many fold the seed may appear large in consequence of very thin seeding, although it is not absolutely a good crop per acre; and notwithstanding these accounts, Thaer, who has repeatedly tried it, says that "its produce in a field is so insignificant that he cannot join in its praise." (vol. iv. s. 162). Perhaps the experiments made in a rich spot in a garden have given results which multiplied produce the above extraordinary returns. Agricultural experiments are unfortunately often made in this way, and consequently give very fallacious results.

BUCOLICS, from the Greek *Βουκολικά* (Bucólica), signifying literally, "poems on the tending of oxen or herds generally." Bucolics are a species of poetry, or rather an exercise in verse, in which the interlocutors are shepherds, husbandmen, and their "mistresses." Great antiquity is claimed for its invention. Some have babbled about the Golden Age and Arcadia; and some have attributed it to the Sicilians, perhaps for no better reason than because their island exhibits abundance of pastoral scenery. Others have said, that on the invasion of Greece by the Persians, when the festivals of Diana were suspended, the country people thronged the temples, and sang hymns to that goddess concerning their rural occupations, which thence were called Bucolics. There has also been equal difference about the name of the inventor, and Diomus and Daphnis, whoever they may be, Stesichorus and Theocritus, has each had his supporters; for the critics have forgotten that it is one thing to sing as shepherds do while tending their flocks, and quite another thing to sing as poets do when relating the life of shepherds.

Theocritus, Moschus, and Bion, have written Bucolics in Greek, and Virgil has copied them in his Eclogues. Calpurnius, a later Latin poet, has shown us how tame and insipid Bucolic poetry may be. Such beauties as these compositions contain, are chiefly comprised in delicacy of expression and refinement of language. Bucolic poetry has been little cultivated by the moderns; the French have converted it into mawkish gallantry; and the rank which it maintains in England may be estimated, when it is stated that Cunningham and Shenstone have been its principal ornaments. Those who deem this subject worthy of further investigation may look to the 'Poetics of Scaliger,' i. 4; 'Salmasius on Solinus,' pp. 851, 867; and the dissertation prefixed by Heyne to his edition of the Eclogues of Virgil.

BUDDHA ; BUDDHISM. Among the religions of Asia, that of Buddha is one of the most remarkable, partly for the peculiar character of its doctrine, and partly on account of the vast number of its followers. From India Proper, the country which gave it birth, nearly every trace of Buddhism has now disappeared; but it has become the religion of the great majority of the inhabitants of the high table-land to the north of the Himalaya, as far as the boundary of Siberia, and it is the prevailing creed of China, of the Peninsula of India beyond the Ganges, of Ceylon, and several islands of the Indian archipelago, and of the empire of Japan. According to an estimate given by Berghaus

('Physikalischer Atlas,' Abth. Anthropographie, No. 4), there are now upon the globe—Christians of all denominations, 390 millions; Jews, 4 millions; Mohammedans, 200 millions; followers of the Brahmaic religion, 170 millions; Buddhists, 397 millions; and heathens, 111 millions.

Though much had been written upon Buddhism, a critical investigation of its origin, its system of doctrines, and the history of its diffusion among so large a portion of mankind, was still a desideratum. Hardly any of the original authentic documents of the sect, which were written in Sanskrit, had been fully examined, and the information which we possessed respecting its dogmas, was almost exclusively derived from sources of a secondary rank. But several distinguished scholars, among whom we may mention Isaac Jacob Schmidt, of St. Petersburg, Alexander Csoma de Körös, at Calcutta, Brian Houghton Hodgson, in Nepál, and George Turnour, in Ceylon, severally engaged in inquiries. At length in 1837, Mr. Hodgson having collected upwards of eighty valuable Sanskrit documents on the subject, generously sent them to Paris, where M. Eugène Burnouf went to work indefatigably upon them, and in 1844 published his 'Introduction à l'Histoire du Bouddhisme Indien.' He compared his original documents with their translations in four or five other languages, and developed the dogmas and the history of this religion, which forms the faith of so large a portion of the population of the world. He continued his labours till his death in 1852, immediately after which was published what he had left fit for publication, though in some degree fragmentary: 'Le Lotus de la bonne Loi, traduit du Sanscrit, accompagné d'un Commentaire, et de vingt-un Mémoires relatifs au Bouddhisme.' These two works form an admirable monument of philological genius united to a sound philosophy.

The origin of Buddhism is involved in much obscurity. Doubts have been raised whether Buddhism is of Indian growth, or whether it was introduced from abroad; the relative antiquity of Buddhism and the religion of the Brahminical Hindus, who follow the doctrines of the Vedas, has been matter of dispute; and the greatest discrepancy prevails with respect to the epoch which, according to various authorities, should be assigned to the founder of the sect. It is somewhat remarkable that, after having been described chiefly from those portions of the globe over which Buddhism now prevails, the most reliable accounts of the genuine system should have been at last found in the language in which it was first developed.

Among those who, contrary to the opinion generally received by the Buddhists themselves, have suspected that the sect did not originate in India, Sir William Jones must be mentioned. The curled or woolly appearance of the hair on the head of the statues of Buddha, many of which are sculptured in a black kind of limestone, combined with other circumstances, led him to form an opinion, that the inhabitants of India, who occupied the country previous to its invasion by the Brahmanic tribes from the north, were of African descent, and that in the sculptured representations of their legislator some of the characteristic appearances of the negro race had been preserved. ('Asiatic Res.' vol. i. p. 427.) But the foundation on which this opinion rests, is in some degree shaken by the fact, that images of Buddha are as frequently seen in white or gray as in black stone; while on the contrary, statues of Krishna, Sûrya, Ganêsa, and other deities of the various Brahmanical sects, with whom the presumed reason of the Buddhists for giving preference to black could have no weight, are nevertheless frequently seen of that colour. Another argument against the supposed African origin of Buddha may be deduced from the enumeration of his *lakshanas* and *vyanjanas*, or points of beauty and peculiar personal appearances, which are so familiar to Buddhists everywhere, that this circumstance alone seems to warrant their antiquity, and to entitle them to at least equal credit in our inquiry into the extant sculptured images of the sage. The original Sanskrit text of the thirty-two *lakshanas* or "characteristics," and of the eighty *vyanjanas* or "peculiar signs" of Buddha, were published in the appendix to an interesting paper by Mr. Hodgson in the 'Journal of the Royal Asiatic Society,' vol. ii. p. 314, &c. Among the former we observe one (No. 14, *suvarna-varnatâ*) which describes Buddha as being of a gold-coloured complexion; and among the later there is one (No. 59, *tunga-nâsikatâ*), according to which he had a prominent (aquiline?) nose. Both these epithets are utterly inapplicable to an individual of the negro race. (See Abel Rémusat, 'Mélanges Asiatiques,' Paris, 1825, 8vo, vol. i. p. 100, &c.) With reference to the curly hair of the statues of Buddha, we may mention that, according to a remark of Colonel Mackenzie ('As. Res.' ix. p. 249), the *Mahāvratas*, a class of *Jaina* ascetics who are not allowed to shave the head with razors, employ their disciples to pull out the hair by the roots; and to the effects of this operation they attribute the appearance on the heads of the images of their *Gurus* or saints, which Europeans suppose to represent curly or woolly hair. It has been suggested by some, that the curls on the head of the images of Buddha might be accounted for in a similar manner. In the list of personal characteristics of Buddha, however, no less than six terms descriptive of his hair are enumerated (*vyanjanas*, Nos. 72—78), which, though some are not very clear in themselves, seem to attach a notion of beauty to its peculiar appearance: this could hardly be the case if the curls had been considered as morbid, and produced by a violent extirpation of the hair. The answer which Mr. Hodgson obtained from a priest in Nepál to an inquiry respecting the reason of Buddha being represented

with curled locks was to this effect, that it was considered a point of beauty; still the notion is, as Mr. Hodgson observes, an odd one for a sect which insists on tonsure.

The Buddhists themselves, however much they may disagree as to the period at which the founder of their religion lived, make no pretensions to a very high antiquity of their sect, but admit on every occasion the priority of the Brahmanic creed.

The Buddhists of Ceylon place the period of Śākya, or Buddha, at the 6th century before the Christian era, which date is confirmed by the testimony of the Buddhist writings, by inscriptions and by medals. The Chinese Buddhists claim a far higher antiquity, but this claim is rejected by M. Eugène Burnouf, and is contradicted by the Sanskrit texts: that it cannot be much later is proved by the writings of classical authors, to whom they were known as Sarmanes, Samaneans (a corruption of the Sanskrit *samana*, stable, unalterable), or Gymnosophists, though the Brahmanic ascetics appear to have been confounded with them under the latter name. 'The Mahawansa,' a chronicle in the Pali tongue, which has been translated by Mr. Edw. Upham in three volumes in 1833, gives a series of continuous dates, which, dating from the death of the last Buddha (Śākya), is no longer embarrassed by the indefinite system of fictions peculiar to the Brahmanic works.

According to the concurrent traditions of the Buddhists, in various parts of Asia, the founder of the sect was the son of Suddhōdana, king of Magadha in South Behar, and Māyā. His name is said to have been Sarvārthasiddha; but he bore several designations, either as Śākya or Buddha, among which are the following: Munī, Sastri, Munindra, Vinayara, Samanta, Bhadra, Dharma Rājā, Sugata; and his titles are, Śākyamuni, Śākyasingha, Sarvārtha-siddha, Sud'hodhani, Gautama, Arcaband'hu, or kinsman of the sun; Māyā, or child of Māyā (delusion), or Māyādevīsuta. The title of Buddha, or "the sage," does not seem to have been given to him till after he had attained eminent sanctity as a teacher of religion. Several of these names appear under somewhat modified shapes in the languages of the various Buddhist nations; thus Śākyamuni has, by the Mongols, been corrupted into Shigimuni; Gautama, preceded by the honorific Sanskrit title of Sramana, "the ascetic," has, in Siamese, become Sommonacodom; the Chinese have converted Magadha into Moki-to, under which name they comprehend India generally; Buddha they have corrupted into Fo-ta and Fo; and Suddhōdana, like many other Sanskrit compound names, they have analysed and translated into their own language by Zing-fan-wang, that is, "the eater of pure food."

The circumstances of the life of Buddha, which we find recorded, are only few. Conformably to the prevailing usage of the country, the infant was, a few days after his birth, presented before the image of a deity, which is said to have inclined its head when the child was brought near its shrine, as a presage of his future greatness. In his tenth year the boy was placed under the guidance of a spiritual instructor, whose name, according to a Mongol account of the life of Buddha, was Bah-Burenu Bakshi. He soon developed mental faculties of the first order, and became equally distinguished by the uncommon beauty of his person. At the age of 20 years he married a noble virgin called Yasōdharā Dēvi in the Ceylonese account of his life. He had by her two children, a son (whom the Mongols call Racholi; the Ceylonese, Rahula Kumareyo) and a daughter. At this period of his life it is related that earnest meditations concerning the depravity and misery of mankind began to engage his mind, and he conceived a plan of retiring from human society and becoming a hermit. His father endeavoured in vain to frustrate this design; Buddha escaped the vigilance of the guards appointed to watch him, and took his abode on the banks of a river, named in the Mongol history Arnasara or Nara-sara, in the kingdom of Udipa. Here he lived during six years, undisturbed in his devout contemplations. At the expiration of this period he came forward at Warnashi (Varanasi, that is, Benares) as a religious teacher. It is said that, by some who heard him, doubts were at first entertained as to the soundness of his mind; but his doctrines soon gained credit, and were propagated so rapidly that Buddha himself lived to see them spread all over India. He died in his 80th year. (Klaproth's 'Asia Polyglotta,' p. 122, &c.; I. J. Schmidt's 'Geschichte der Ost-Mongolen,' pp. 312, 313.)

To become a disciple of Buddha it was sufficient to declare a belief in him; but the neophyte had to shave his hair, to wear a cloak made of yellow rags, and to study under an older believer. No person could be admitted to the society by a single member: it must be done in general assembly. This assembly, of which Śākya was the chief, consisted of male and female mendicants, who bound themselves to perpetual chastity and poverty, and of believers who had not adopted any ascetic rule. From among the ascetics, however, were chosen the elders, according to their merit and seniority. The highest rank was that of the aryas, or those who had comprehended the four axioms which are the foundation of the Buddhist doctrine: that is, 1, that there exists pain; 2, that all that is born in this world suffers pain; 3, that it is necessary to liberate ourselves from it; and, 4, that knowledge alone offers the means of this deliverance.

Transmigration, attaching rewards to good acts and punishments to bad, leads to the notion of expiation, which ought to be effected by the performance of good actions; but the only form which it receives in practice is confession, and this was instituted by Śākya himself.

The worship of Buddhism is extremely simple; the ceremonies consist in offering flowers and perfume, accompanied with instrumental music, hymns, and prayers. There were no bloody sacrifices, and the worship is in fact not addressed to one god, or a number of gods, but to a figure of Śākyamuni, and the buildings enshrining a part of his bones. An image and relics, this is the whole of the worship of the Buddhists. Hence the legends dwell so much on the personal beauty of Śākya, ascribing to him 32 characteristics of beauty, and 80 secondary signs, and hence also Buddha is always represented as a man sitting and meditating, and not with the exaggerated attributes of the Brahmanical deities. This system has undergone considerable modifications. Other images have been introduced, such as the five dhyanī Buddhas, of which drawings have been published by Mr. Hodgson, but which he considers as mere personifications of the phenomena of the physical world: they on the whole, however, maintain the form of a man who meditates or teaches.

The relics consist of the ashes of the body of Śākya, which, after the body was burnt, were collected into eight metal cylinders, and buried under the like number of chaityas. The uninterrupted tradition of 17 centuries confirms the destination of these topes, or columnar erections, of which many have been opened within the last few years, by General Ventura, Major Cunningham, Lieut. Maisey, and others.

The books now extant form three classes: the Sutrapitaka, or discourses of Buddha; the Vinayapitaka, or the discipline; and the Abhidharmapitaka, or the manifested laws or metaphysics. The whole are termed Tripitaka. This division is also recognised among the Chinese, who name them sacred books, precepts, and discourses.

The Sūtras are dialogues in which Śākya is the teacher. Śākya always commences a Sūtra with the formula, "Lo, what I have learnt." They were evidently written when the system of castes prevailed in India, and which were then Brahmans, Ksatriyas, Vaisayas, Sudras, and Chandalas, with some subdivisions; the names of the castes are continually quoted.

A second class of the Nepālese works are the Avedanas, which are legends; they are later and of various dates.

The Indian books, Sanskrit and Pali, show us in Buddha a religious reformer, desirous above everything to change the manners of his contemporaries. An infinite charity,—the desire of imparting to others the satisfaction enjoyed under the rule of an excellent doctrine,—giving a strong impulse to proselytism among all ranks and from all castes,—the admission to the priesthood of persons from classes the most despised, whenever they had rendered themselves worthy of this supreme honour by their virtue,—in one word, equality before God, such were the characters of the doctrine presented by Śākya. M. Eugène Burnouf ('Introduction à l'Histoire du Bouddhisme Indien') relates a response of the great reformer, which at once enables us to comprehend the principle of the new religion. The Brahmans had been ridiculing him on account of a new disciple, whom he had converted when sunk to the lowest degree of abasement and misery. "My law," he said, "is a law of grace for all; and what is this but a law of grace for all? It is a law under which the most miserable mendicants may make themselves religious." "Remarkable words," says M. Burnouf, "of which the spirit has propagated Buddhism, and which was still vivid at Ceylon even at the beginning of the present century, when a religious, disgraced by the king for preaching to the miserable and despised caste of Rhodias, answered nearly the same as Buddha himself: Religion ought to be the common good of all."

The Buddhist compositions are not written in the rich but simple style of the Mahābhārat, but yet not in the monotonous idiom of the Purānas, and the plan is somewhat inartificial. In the Sūtras Buddha is usually placed in some town of India, where he is represented as surrounded by an assembly of religious hearers, sometimes with the addition of a number of gods, to whom he preaches his doctrines, which, however, contain nothing of the mythological machinery subsequently introduced. None are mentioned but Buddhas, of whom Śākya was the last, and all are men like himself, the sons of Brahmans, or kings. He, however, claimed a previous existence, and occasionally confirms his doctrine by relating what happened to himself, or his disciples, in a former life.

Śākya admits and names a number of the brahmanical gods, but deems their power inferior to that of Buddha; and he taught that the Buddha, a supreme intelligence, was involved in an always moving progress of transmigration, through animals, criminals, men, and gods; that all the visible world is in perpetual change; that death succeeds life and life death; but by the practice of six transcendent perfections—alms, morals, science, energy, patience, and charity,—a man might hope to obtain rest from this continued change, and arrive at the state of Nirvāna, deliverance or annihilation.

The means of conversion used by Śākya were preaching, with reference to his own holy life, the possession of knowledge, and the performance of miracles.

To diffuse his doctrines, Śākya employed preaching, a new means in India (absolutely unknown to Brahmanism, which then reigned paramount in that country), which perfectly suited the popular character of his instruction, and which was the foundation of his proselytism. Religious truth was no longer, as with the Brahmans, the exclusive possession of privileged castes, but became the patrimony of all who were willing to acquire it. It was this mode of propagation that so

rapidly multiplied his adherents, the *sectateurs* of the reformer, and which at the same time rendered Buddhism an object of bitter enmity to the Brahmans, whose religious system, founded principally on the existence and perpetuity of a sacerdotal race, it ruined. Buddhism, however, did not always abolish caste where it prevailed; it was accepted, but Buddhism thus brought together by the common band of charity those who had been until then separated by insurmountable barriers. It is thus that these divisions subsist even yet in Ceylon, of which the population was among the earliest to embrace Buddhism. But if this religion does not abolish caste, it does not consecrate it like the Brahmans; it is not imposed in any way by their institutions; and hence, in those countries where castes were unknown, as Tibet, Siam, Birma, &c., they have not been introduced with these doctrines, which show themselves, consequently, in a form in some degree democratic.

Buddhism distinguishes itself from Brahmanism not only by a character that we may term democratic, but still more by the extreme simplicity of its religious doctrine, and by the almost complete absence of dogmas. All its teaching is essentially moral, and this morality rests upon an imitation of Buddha; that is to say, upon the religious life represented as the ideal for a man in this world. Imitate Buddha, conform yourself as much as possible to this type of perfection,—such is the supreme precept of the religion; for the rest, this religious and ascetic life is not exclusively reserved for the men. Buddhism has convents for females, in which similar rules are imposed and observed. It has, however, one point of resemblance with Brahmanism—the syllabic designation of the chief deity—Om, or Aum—is a word of reverence with both sects.

It is by the practice of these virtues, and by faith in Buddha, that man arrives at Nirvāna; that is to say, to deliverance—to supreme happiness. But what is this supreme happiness? According to some it is the absorption of the individual life into the Deity; according to others it is annihilation; and lastly, according to the Tibetans, it is the death of the body, the deliverance from physical sufferings, or rather the enfranchisement from the law of transmigration. Although these explanations vary, it is easy to recognise in them that the idea of the Nirvāna is that of repose, the highest notion of happiness in India. The aim of Buddhism is, then, to conduct man to happiness by the exercise of virtue.

One of the means is confession. Confession leads to casuistry; that is to say, the classification of different species of faults, and this science occupies a large place in the teaching of the religion.

The dogmas are simple, at least in ancient Buddhism. It is sufficient to believe that Buddha was a man of a supreme degree of intelligence and of virtue, who is proposed to every one as a model and rule of life.

Latterly, Buddhism lost much of its moral tendency, and mythological conceptions, borrowed from Brahmanism, were mixed up with it. The books named *Tantras* show us in the highest degree the confusion of these two rival faiths. We see the worship of Śākya, the Dhyani Buddhas, or four stages of contemplation, and of Adibuddha, mixed up with the worship of Siva and the female divinities of the Sivaites. It is, in effect, from the theory of the supreme Buddha with the superhuman Buddhas and Bodhisattvas, that the primitive monotheism of Buddhism has ended by approaching to a veritable polytheism. Although Buddha may be the name by which Śākya is designated, it does not essentially belong to that personage. The word Buddha does not properly mean a man, it is rather a title by which some of the privileged ascetics are called. The Buddhists name those Bodhisattvas who, by the practice of all the virtues and the exercise of meditation, are ripe for the supreme state of Buddha perfectly accomplished. He who wishes to attain to this state cannot do it of his own will; he must, during several stages of transmigration, have merited the favour of one or more of the ancient and gigantic Buddhas, in whose reality most Buddhists believe; and it is only when in possession of their favour, in one of those heavenly places above the earth, that he awaits, under the title of Bodhi-vattu, the moment of his coming into the world. Descended upon earth, he is not yet Buddhas; it is not till he has undergone all the proofs, accomplished the most exalted duties, penetrated the most sublime truths by sciences, that he becomes Buddhas. Then he has the power of delivering men from the conditions of transmigration, by teaching them charity, and showing them that those who practise the duties of morality in this life, and strive to attain scientific knowledge, may one day attain the supreme state of Buddha. At length, having taught the law, he enters into the Nirvāna. Śākya is but one of these mysterious Buddhas.

The Buddhist doctrine comprehends a very abstruse metaphysical system, in which re-appear, under essentially Indian forms, speculations on the absolute, on the first cause of the universe, and on the essence of things. All these problems are treated of in the Abhidharma (one of the Buddhist books) just as they are in modern European books, with identical solutions occasionally, but differing according to the nature of the mind producing them.

The earliest allusion to the sect of Buddha in any western writer has been supposed to occur in Herodotus (iii. c. 100; Korai, 'Prodr. Hell. Bibl.' p. 271), who says of certain Indians, that they kill no animals, and live on the vegetable products spontaneously produced by the soil. Nicolaus Damascenus may, however, possibly allude to the very words of Herodotus, in a detached passage where he speaks of an abstemious

sect called Aritioni ('Αρίτιονι), which name seems to be the Sanskrit Arhat, or Arhata, a very common designation of the Jaina sect, who are even more distinguished than the Buddhas by their extreme tenderness for animal life. Strabo (xv. c. 1, p. 712, ed. Casaub.), on the authority of Megasthenes, states that there are two classes of philosophers among the Hindus—the Brachmanes and Garmanes; and from the account which he gives of the latter, who are by Clemens of Alexandria ('Strom.' i. p. 305) more correctly called Sarmanes, it is clear that by them the Buddhists are to be understood. The name Sarmanes appears to be the Sanskrit word Sramana, "a religious mendicant, an ascetic." A Buddha beggar is thus designated by a Brahman in the 'Mrichhakati,' a Sanskrit drama, supposed by Mr. Wilson to have been written either one century before or two centuries after our era (act viii. p. 212, ed. Calcutt.). We recognise the same word under a slightly modified shape in the first component part of the name of the Indian philosopher Zarmanos Chanes (Ζάρμανος Χάνης, written in some manuscripts Ζαρμανοχήγας, Ζάρμανος Χήγας, Ζαρμανοχάνης; and in Dion Cass., liv. c. 9, Ζάρμαρος, Σάρμαρος, or Ζάρμακος), who came to Europe with an embassy from King Porus to Augustus, and voluntarily burnt himself at Athens. (Strabo, xv. c. i. pp. 719, 720.)

Two very remarkable passages on the various sects prevailing in India occur in Clemens of Alexandria. In the first passage ('Strom.' lib. i. p. 359, ed. Potter) he says that there are two classes of philosophers in India, the Sarmanæ and the Brachmanæ. "Among the Sarmanes, those called Hylobii (ὕλοβιοι, Mountagu thinks, should be read instead of ἀλλόβιοι) do not dwell in towns or houses; they are clad with the bark of trees, eat acorns, and drink water with their hands; they know not marriage, nor procreation of children." He then proceeds to say that "there are likewise among the Indians persons obeying the precepts of Boutta (Βούττα), whom they venerate like a god, on account of his extreme sanctity." Here the followers of Boutta (Buddha) are clearly distinguished from both the Brachmanæ and Sarmanæ. In the second passage (p. 539, ed. Potter), Clemens speaks of a sect whom he calls Semnoi (another corruption of the Sanskrit name Sramana?), "they go naked all their lives; they make it a point always to speak the truth; and they inquire into the future. They worship a certain pyramid, beneath which they believe the bones of some god to be deposited. Neither the Gymnosophistæ nor the Semnoi have any intercourse with women, for they deem this contrary to nature and to law, and for that reason they adhere to chastity. There are also females of this class (Σεμναί) who live in perpetual virginity." The pyramids here spoken of are evidently the dagobas of the modern Buddhists.

The statements respecting the religion of India and China given by the two Arabian travellers who visited these countries in the 9th century (Renaudot, 'Anciennes Relations des Indes et de la Chine,' &c., Paris, 1718, 8vo) are too vague to enable us in every instance to distinguish whether the "pagans," of whom they speak, were Buddhas or not. In the report of the first traveller (l. c. p. 3) we meet with an allusion to the impression of a foot on Adam's Peak in the Island of Ceylon, a spot known to Ebn Batuta (Lee's translation, p. 189) as a place of pilgrimage, which it has continued to be till the present day with the Ceylonese Buddhists. The second traveller, in speaking of the natives of India, calls their priests Brahmans (l. c. p. 107), and in the account which he gives of their ascetics, and of their religious institutions generally, nothing occurs that would, in our opinion, admit of an application to the Buddhas. These statements, though not very explicit, are yet interesting, as they seem to attest the expulsion of the Buddhists from India some time previous to the 9th century, and the existence of the sect in Ceylon.

In the Ante-Islamic portion of the Arabic chronicle of Abulfeda, published by Fleischer (Abulfeda, 'Hist. Anteislamica,' &c., ed. H. O. Fleischer, Leipzig, 1831, 4to), there is a curious chapter on the various tribes of India (p. 170, &c.) given on the authority of Shehrestani, a writer who flourished in the first half of the 12th century. Most of the Indian tribes, or rather sects, there noticed, are easily recognised, even under the somewhat adulterated names given to them by the Arab, as various branches of Brahmanic Hindus; and the only sect, the name of which bears any similarity to that of the Buddhists, the Behuditæ (al Bahūdiyyah, in the Arabic text), are described in a manner which removes every possibility of their being taken for followers of Śākyasinha.

We have already alluded to the indirect testimony which Ebn Batuta gives of the existence of Buddhism in Ceylon, in describing the pilgrimage to the impression of Buddha's foot on Adam's Peak. In his account of Hindustan, he describes the burning of widows and other practices reprobated by the Buddhists, the prevalence of which is sufficient to convince us that Brahmanism was at that time the established religion of the country.

Marco Polo, who visited Tangent during the second half of the 13th century, describes the religious institutions of Kampion, the principal city of that province, in a manner to convince us that Buddhism was then the prevailing creed there, though the name is not mentioned. "The idolaters of Kampion," says he, "have many religious houses or monasteries and abbeys, built after the manner of the country, and in these a multitude of idols, some of which are of wood, some of clay, and some of stone, and covered with gilding. These images are held in extreme veneration. . . . Those persons amongst the idolaters who are

devoted to the services of religion lead more correct lives, according to their ideas of morality, than the other classes, abstaining from the indulgence of carnal and sensual appetites." (Marsden's 'Travels of Marco Polo'.)

An early account, communicated probably by travelling merchants, of a Lama, or spiritual chief, among the Buddhist Tartars, seems to have occasioned in Europe, the report of a Prester John, or a Christian Pontiff, resident in Upper Asia. It deserves, however, to be noticed that Barhebræus ('Hist. Dynast.') speaks of a prince of the "Eastern Turks," who was a Christian, and who was named Ung-khan, or King John (*Malic Yuhannâ*): this prince reigned about the year 1202, and was dethroned by Gengiskhan.

However small is the information to be gathered from these passages of foreign writers as to the history of Buddhism, it is at least in accordance with the traditions preserved among the Buddhists themselves. For several centuries after the appearance of Sâkyasinha his sect seems to have flourished in India, and to have been tolerated by the Brahmans in nearly the same manner as the various divisions still existing among Hindus who follow the religion of the Vedas. Buddhism appears during this period to have penetrated the peninsula in every direction; and a succession of men of different parts of India, pre-eminent for piety, and considered as the living types of Buddha, followed him as his (figuratively) lineal descendants, and as the patriarchs or spiritual heads of the sect.

The numerous Buddhist temples, the remains of which are scattered over a wide extent of country in India, must be referred to this period. These remains it is not difficult to distinguish from others often found in their immediate neighbourhood, but erected for the purposes of Brahmanical worship. The principal characteristics of temples built for the Buddhists are the dagobas and the images of Buddha. The dagoba is a hemispherical or sometimes columnar structure containing some relic of Buddha, which usually stands either within or (as in Ceylon, Siam, &c.) close by a Buddhist temple, and is supported by a pedestal, generally of a cylindrical shape, which varies in height. [HINDU ARCHITECTURE.] All images of Buddha represent merely human figures in a contemplative posture, sometimes standing upright or reclining, but more frequently sitting on a bench, or squatted down with the feet crossed and resting upon the thighs; the forefinger of the right hand sometimes rests on one of the fingers of the left, but usually the left hand rests upon the left knee, and the right hand is placed on the lap, being held open as if to receive an offering. The hair is always curled almost in the fashion of a wig, and the ears are extended and drawn down as if by the weight of some ornament suspended at them. A number of small cells is often seen near a Buddhist temple, apparently intended to afford shelter to pilgrims, or to ascetics and priests permanently resident near the sanctuary.

Ruins distinguished by these peculiarities have been found near Benares, at Buddha Gaya in Bengal, at Bag in Malwa, near the Ajunta pass, at Ellora, at Nasik, at Juner, at Carli, on Salsette, and at Guntoor. Some have even supposed that ruins of a similar structure, which have been found at Bamian in the Soliman Mountains, and at Manikyala in Afghanistan, belong to the same class. Those of Boro Bodo (or Bura booder) in Java, cannot be mistaken, and prove undeniably that Buddhism once prevailed in the very centre of that island. The simultaneous occurrence of traces of Brahmanic and of Buddhist worship in several of these places is most remarkable, and has not yet been satisfactorily accounted for: the most likely mode of solving the problem is, in our opinion, one of the three explanations suggested by Erskine, namely, that this proximity of their sanctuaries attests the friendly spirit that once prevailed between the two sects. Many notions peculiar to the mythology and cosmography of the Brahmans seem at an early period to have been received by the Buddhists, and to have been by them admitted as part of their own belief. This remark is well illustrated by Dr. Francis Buchanan's paper on 'the Religion and Literature of the Burmas' ('Asiat. Res.' vol. vii.), and by many passages in Sangermano's 'Description of the Burmese Empire,' edited by Dr. Tandy (Rome, 1833), which would, we think, be found on comparison to agree almost literally with passages in the Paurânic works of the Brahmans; and Captain Low, in his account of Tennasserim ('Journal of the Royal Asiatic Society,' vol. ii. p. 257), tells us that in that province dramatic representations founded on the history of Râma are a favourite entertainment of the inhabitants. We merely hint the probability of some influence having been exercised by this adoption of Brahmanic notions upon the architecture and sculptured decorations of temples, &c. erected by the Buddhists; and the possibility that, where remains of buildings of a Brahmanic character are found near others of Buddhist character, both may be the work of the latter sect.

The first foreign country into which Buddhism was introduced from India appears to have been the island of Ceylon. According to the traditions preserved in the Mahâvansi and Râjâvali, chronicles of Ceylon, written in the Pali language, the island received its first civilisation through Vijaya, the son of Sinhabâha, king of Waggo (in the northern Circars); who, being expelled from his father's kingdom, embarked with 700 followers, and landed on Ceylon on the day of Buddha's death; that is, according to the Cingalese computation, in April, 543 B.C. But Vijaya himself was not a Buddhist; and although there is a notion of a primeval Buddhism in Ceylon previous

to the age of the reputed founder of the sect, yet it was not till B.C. 307 that Ceylon was converted. Nearly eight centuries later, a learned priest named Buddha-ghôsa, who came from Jambudwipa, on the continent of India, amplified and commented upon the tenets of Buddhism. This is said to have been done in the reign of king Mahânâma, A.D. 410-432. It deserves to be noticed, that according to the Mahârazaven, a chronicle in the Birman language, Pali books (and the doctrines of Buddha?) were brought from Ceylon to Pegu by a priest named Boudogosa; the date assigned to this occurrence is the year 940 of the Birman era, corresponding to A.D. 397. ('Alphabetum Barmanum seu Regni Avenensis,' Edit. alt. Rom. 1787.) That the Birmans still acknowledge the reception of their religion and laws from Ceylon is attested by the curious fact that, about the year 1790, the king of Ava sent at separate times two messengers to Ceylon, to procure copies of their sacred writings; and in one instance the Birman minister made an official application to the Governor-general of India to protect and assist the person charged with the commission. (Symes, 'Embassy to Ava,' p. 304.) An opinion seems even to prevail among the Talapoints or priests of Ava, that out of the Birman empire and the island of Ceylon, there are no true and legitimate priests of the laws of Buddha. (Sangermano, p. 83.) Two figures of Gaudama were sent from Tayoung, in Birma, by Capt. Hannay to Col. H. Burney, with inscriptions in the Deva-nagari character, of which the following is a part: "The not doing of every kind of evil, and purifying and cleansing the heart: these above-mentioned are the precepts of Buddha."

Of many of the sovereigns of Ceylon we find it mentioned that they formed tanks, or built and restored edifices for various religious purposes. Mahâsên, who reigned from A.D. 275 till 301, entered into negotiations with Guhasêva, king of Dansapura in Kalinga, to procure the surrender of a relic called the Dangistra Dalada, or right canine tooth of Buddha; it arrived in Ceylon during the reign of Mahâsên's son (A.D. 308), and has since then on several occasions played a conspicuous part in the history of the island, owing to the importance attached to it by the inhabitants. As early as the year 209 of our era we find a schism among the Ceylonese Buddhists mentioned; it originated in the doctrines put forth by one Wytooliya, which were adopted by the priests resident at a temple called the Abayagiri vihâra. An inquiry was instituted, and the doctrine having been found incorrect, the books in which it was set forth were destroyed. These strong measures did not, however, effectually check the progress of the schism; and during a considerable period we find indications of the alternate triumph and oppression of the heretical party. Another heresy, called the Wijrawâdiya, is stated to have been introduced into Ceylon from the continent of India during the first half of the 9th century.

With regard to the Cingalese, Mr. Robert Spence Hardy has published two valuable works, containing an account in considerable detail of Buddhism as it exists in Ceylon. In the first, 'Eastern Monachism,' which appeared in 1850, he has collected from Cingalese authorities an 'account of the origin, laws, discipline, sacred writings, mysterious rites, religious ceremonies, and present circumstances of the order of mendicants founded by Gôtuma Budha;' the second, 'A Manual of Buddhism, in its modern development; translated from Singhalese MSS.' appeared in 1853; and comprises a full relation of the doctrines and many of the legends, connected with the faith. The main doctrines are the same as those of the Sanskrit; the variations from them, as well as those of the legends, are such as have been introduced at subsequent periods, and we have preferred taking the statements from the original sources; but Mr. Hardy's books are well worth consulting.

But whilst Buddhism had thus gained ground in Ceylon, and was from thence propagated to the eastern peninsula, it had to endure in India a long-continued persecution, which ultimately had the effect of entirely abolishing it in the country where it had originated. The motive of these persecutions we confess ourselves unable fully to discover. That the caste of the Brahmans could not without jealousy and alarm witness the progress of a sect which threatened to overthrow their authority, and to deprive them of all those privileges which a creed and a social constitution, sanctioned by the Vedas, secured to them, is natural to suppose. But it is less intelligible why Indian sovereigns, after so long a period of toleration, should have consented to lend the Brahmans their aid in oppressing a class of their subjects whose principles, it would appear to us, ought rather to have recommended them as the natural protectors of the royal and civil authority against the ambitious arrogance of an hereditary priesthood; and the perplexity of this question is still increased by the forbearance shown in every part of India to the Jains, a sect so strikingly similar to the Buddhas, in all those particulars at least which seem to have drawn upon the latter the hatred of the Brahmans.

Mr. Wilson ('Sanskrit Dictionary,' 1st. edit., preface, pp. xv.-xx.) has shown that the religious wars of the Brahmanical Hindus with the Buddhists commenced in the 5th, and continued till the 7th century of our era. They have evidently contributed to accelerate the diffusion of Buddhism in other countries, though even in India the sect does not seem to have been entirely extinguished for several centuries after the persecutions terminated. Buddhism appears to have been first introduced into China about the year 65 of our era, by the authority of the

emperor Ming Ti. (Du Halde, 'Hist. of China,' &c., vol. iii., Eng. trans. 1741, 8vo.) A translation of some of the sacred writings of the Buddhists into Chinese is, however, stated to have been made in A.D. 418, by a priest from the northern part of India, whose name was Foo-too-pa-to-lo. (Rémusat, 'Mélanges Asiat.' vol. i. p. 116.) According to the Chinese and Japanese list of Bodhisattwas, Pan-jo-to-lo or Banneyadara, the 27th of the series, was the last representative of Buddha, who died in India (A.D. 457); his successor, Bodhidharma, went to China (A.D. 499), and was followed by five Buddhist patriarchs there. From China Buddhism was subsequently extended to Corea, A.D. 528, and to Japan, A.D. 552. M. Stanislaus Julien says, Buddhism was introduced into China about A.D. 65, and spread rapidly—the Buddhist books of India having been brought immediately by missionaries, by pilgrims on their return, and by the exiles driven out by the persecution of the Brahmins; and he gives a list ('Journal Asiatique,' for Nov.-Dec., 1849), of the works translated into Chinese. He states also, that there is a Chinese catalogue, printed in 1306, with the Sanskrit and Chinese titles ranged side by side, to the number of 1440, forming 5586 volumes. Some of these works are translated also into Tibetan and Ugrian. In 1853 and 1857, M. Julien also published the translation of a Chinese work, the 'Pilgrimage of a Chinese Buddhist pilgrim, from China to India, to study the religion of the great reformer in his own country.' The volumes contain much interesting matter, particularly as relates to the geography of the countries he passed through; but his statements as to the doctrines of Śākya differ in no material degree from those of Burnouf.

About the middle of the 5th century, Buddhism seems to have been carried to Java; whither, however, Brahmanical settlers had probably preceded it. It is as yet uncertain whether the Buddhism of Java was of Ceylonese or of Indian origin. According to a tradition current in Java, the strangers, who civilised the island, came from Kling (that is, Kalinga, or the northern Circars), a name by which the modern nation of Java seem to designate the whole continent of India.

Buddhism was also introduced into Cashmir very early. According to the local history it continued to flourish there till the reign of Nara, B.C. 298, when the Brahmins expelled the followers of Buddha, and burned their temples. (Wilson, 'Asiat. Res.,' vol. xv. pp. 26 and 81.)

Dr. F. Buchanan (Hamilton) is of opinion that the time of the introduction of Buddhism into Nepāl may be fixed about the commencement of the Christian era, when "Śākya, the last great teacher of the Buddhists, passed through the country and settled at Lassa, where he is supposed to be still alive in the person whom we call the Grand Lama." ('Account of Nepāl,' p. 10. Compare pp. 32, 56, 190.)

From the Mongol chronicle, published by Schmidt, we learn that Buddhism was for the first time introduced into Tibet during the reign of Hlatotori, in A.D. 407. The great grandson of that king, Srongdsan Gambo, who ascended the throne in A.D. 629, sent Tongmi Ssambhoda, attended by sixteen companions, into India, for the purpose of being instructed in the art of writing. Along with an alphabet, which has till the present day preserved its similarity to the Indian Devanagari character (see the plates accompanying Mr. Hodgson's paper in the 16th vol. of the 'Asiatic Researches') these missionaries seem to have carried the first writings on the religion of Buddha into their native country. But not all the succeeding kings of Tibet were favourable to the new religion. Glang Dharma, who reigned from 902 to 925, as well as his son Gorel Shakikchi (925—977), were hostile to Buddhism, and persecuted its followers. After a period of persecution which lasted 86 years, the doctrine was re-established in Tibet, in the year 988. M. Huc (in his 'Souvenirs') has given specimens of a Tibetan work attributed to Śākya, entitled the 'Forty-two points of instruction delivered by Buddha,' and these points are entirely in unison with those produced from the Sanskrit by M. Burnouf. Nearly three centuries subsequent to this restoration Buddhism was introduced among the Mongols, during the reign of Godan, a grandson of Gengiskhan, who was converted to the new religion A.D. 1247, by Śākya Pandita, a teacher (Bodhisattwa?) who came from the south. (Schmidt's 'Ssanang Ssetsen,' pp. 25, 29, 48, 113, &c., and the notes of the translator, pp. 325, 329, &c.)

M. Huc says ('Souvenirs d'un Voyage dans la Tartarie, le Thibet, et la Chine, pendant les années 1844, 1845, et 1846'), that of all the Buddhist nations he has visited, the Mongolians appear to be the most sincere; then come the Tibetans and the Cingalese; but that the Chinese are merely nominal followers, and have almost universally fallen into complete scepticism.

The collection of writings regarded as sacred by the Buddhists is probably as voluminous as that of any sect that ever existed. The language in which the Buddha sages originally committed their doctrine to writing we believe to have been the Sanskrit, from which they were subsequently translated into the Pali, and into other languages current in the several countries where Buddhism was introduced. A considerable number of Sanskrit records of Buddhism were some years back procured in Nepāl by Mr. B. H. Hodgson; and it is but natural to suppose, that among them some of the ancient and original treatises on the doctrines of Buddhism should have been preserved. The most important of these sacred writings in the estimation of the Nepālese Buddhists are nine "Purānas," also named the nine "Dharmas," narrative works, in which elucidations of the Buddha

doctrines seem to be blended with a legendary account of the life of Buddha and the most eminent sages of the sect. Besides these they possess works called "Tantras," which contain prayers and forms of invocations, and are illustrated by ample commentaries; and also collections of prayers, apparently composed for use on certain occasions, which are called "Dhāranis." (See Mr. Hodgson's enumeration of the principal existing Buddha writings of Nepāl, in the 16th volume of the 'Asiatic Researches,' p. 422, &c.) Quotations in Sanskrit from a collection of "Sūtras," or short aphorisms, attributed to Buddha himself, occur in Sanskrit works on the Vedānta philosophy.

In the Essay on Buddhism by Kitelegama Dewamitta Unnanse, a native of Ceylon (printed in the Ceylon Almanac for 1835, pp. 211—229), 84,000 sermons preached by Buddha are mentioned (p. 226), which the writer of the Essay says may be contemplated as his personification (p. 229). The Mongol Buddhists possess a sacred work called "Gandjour," which is written in the Tibetan language. Timkowski saw a copy of it in a temple at Purga, in the country of the Kalkas Mongols, which consisted of 108 volumes. Chests revolving on an axis, and covered with prayers in large gold letters, are frequently placed in the Buddhist temples among the Mongols, in order that persons who cannot read may come and turn them round as long as their zeal prompts them, which is considered as efficacious as if they recited the prayers themselves.

It is a notion deeply rooted in the minds of all Hindus, often repeated in the Vedas, and variously explained and commented upon by the different schools of Brahmanic philosophy, that the visible world and everything relating to it is but the transient manifestation of the Deity, without real or permanent existence; that the confinement of the human soul, itself an emanation of the Divine spirit, in a perishable body, subject to all the changeable accidents of matter, is a state of misery; and that every effort of man during life should be directed towards ensuring the entire emancipation of his soul after death, that is, not only its liberation from the necessity of undergoing another birth, and being invested with a body, but altogether its release from individual existence, and its direct return to a lasting union with the Divine Being. This notion developed in a peculiar manner, forms likewise the basis of the Buddha creed.

The Buddhists of Nepāl, who have preserved the ancient doctrines of the sect with the greatest purity, and concerning whose religious notions our information is as yet more explicit than any that we possess of the tenets held by the Buddhists of other countries, are divided into four schools, which differ partly in the manner in which they teach that the Divine spirit was active in the production of the world, and partly in the method which they prescribe for effecting the liberation of the soul after death. We will endeavour briefly to state the peculiar doctrines of each of these schools, following chiefly the 'Quotations in Proof,' published by Mr. Hodgson in the 'Journal of the Royal Asiatic Society,' vol. ii. p. 295, &c. All concur in admitting the primeval existence of the Deity, who was when nothing else was, and who is thence called Adi-Buddha or "the First Buddha."

1. According to the Swābhāvika school, Swābhāva, a sort of plastic faculty, springing from, or rather identical with, Iswara, or God, is the source from which the elements and all things and beings proceed, and into which they are ultimately to be re-absorbed. The universe constantly revolves between Pravṛtti and Nirvṛtti, or creation and re-absorption or annihilation; and this eternal change of existence and non-existence is the system and law of nature, without any co-operation of will or design on the part of Iswara. (Hodgson, l. c. p. 297, No. 9.)

2. The Aiswarika school attributes more of a personal character to the Deity, and asserts that the creation of the world was the deliberate act of Iswara. Nirvṛtti, that is, perfect calmness or repose, is his proper and enduring state: but for the sake of creating the universe he became Panchajñātmika, or "endowed with five-fold consciousness," and produced the five divine Buddhas (Vairocana, Akshobhya, Ratnasambhava, Amitābha, and Amoghasiddha), who became the authors of the elements, and by the agency of the five Bodhisattwas, beings produced by them, were the creators of the world. These five Bodhisattwas therefore, as delegates of Iswara, produced all things by their fiat. (Hodgson, l. c. p. 299.)

3. The Kārmika school (which along with the Yātnika is supposed by Mr. Hodgson to be of more recent origin than the two first) appears to have speculated chiefly on the means best calculated to procure the release of the soul from its connexion with matter; and as it deduces the procession of all things into existence from avidyā (error, delusion), so it maintains that the regressive movement towards non-existence must be effected by true knowledge. The "error" here alluded to is the groundless belief in the reality of the external world. This belief, when arising in the un-embodied sentient principle, is attended with a longing after the objects which it supposes to exist: hence individual consciousness springs, and a subtle personal frame forms itself as the seat of that consciousness: a perception of sensual objects follows, which produces desire in the subtle frame, and leads to its corporeal conception and physical birth. The progress of the soul towards matter is therefore the effect of a succession of acts (Karma—whence the name of the school Kārmika) on the part of the soul; and its liberation must be sought by relinquishing the erroneous notion of the reality and stability of external objects; for when this great error is

abandoned, all its consequences vanish with it, along with all mundane things and existences which are only derived from thence. This school likewise inculcates the doctrine which is very current in India, that the actions of a man during former existences determine his destiny in the present life: "Although I had acquired a perfect body, still in this body even defect again appeared, because I had still to expiate a small portion of the sins of former births: so said Sākya Sinha." (Hodgson, l. c. p. 304.)

4. The Yātnika school has directed its attention to the same problem as the preceding, and proposes to solve it in a similar manner. The cause of the creation of the world, say its followers, is Yatna, that is, an effort or a determined will on the part of the Creator. In the same manner in the affairs of this world all difficulties are overcome by Yatna; and so the attainment of that wisdom which procures the liberation of the soul from matter depends on (Yatna) a conscious intellectual effort. (Hodgson, l. c. p. 305.)

Various terms are in use to denote the state of final liberation of the soul, which is by all these sects proposed as the object to which man should aspire; but the expression, which Buddhas seem to be particularly fond of employing, is Nirvāna. This word is properly a passive participle of the Sanskrit root *va*, "to blow" (as the wind), with the preposition *nir*, "out, away from," prefixed to it; and its primary meaning is "blown out, extinct," as a candle which is gone out, and hence "departed, defunct;" but the word is likewise used with the preposition *nir* taken in a negative sense, and it then signifies "calm, unruffled," or, employed as a substantive, "calmness, tranquillity;" whence is derived its use as a description of the happy state of imperishable serenity and apathy at which the soul arrives on its re-union with the Divine Essence.

The popular belief in Nepāl attributes the superintendence of the work of creation especially to Padmapāni, one of the five divine Bodhisattvas above alluded to. He is represented as having produced the three Hindu deities Brahmā, Vishnu, and Siva, and as having assigned to them respectively the task of creation, preservation, and destruction. It is Brahmā therefore who, according to this account, created the world. Another account conceives Manjusri to have been the appointed architect of the world, while Padmapāni, by Adi-Buddha's special command, created all animate things.

The cosmography of the Buddhists divides the entire universe into four principal divisions. The first consists of thirteen Bodhisattva-bhuvanas, or mansions, created by Adi-Buddha, and including the Agnisht'ha-bhuvana, his own eternal abode: devout followers of Buddha will proceed to one of these mansions after death. Below them is the second division, which consists of eighteen mansions, called Rūpyavachara-bhuvanas, and created by Brahmā; farther down is the third division, comprising the six Kāmavachara-bhuvanas, which are subject to Vishnu; and below them are the three Bhuvanas called Arūpyavachara, superintended by Siva, and forming the fourth division. Pious worshippers of Brahmā, Vishnu, and Siva will, after death, proceed to these divisions respectively. (Hodgson, 'Transact. Roy. Asiat. Soc.' vol. ii. pp. 233, 234.) Below these Bhuvanas another series of mansions begins, which belong to Indra, Sūrga (the sun), Chandra (the moon), Agni, Vāyu, &c. Then follows the earth, with its seven dwipas or continents, separated by seven seas. Below the earth is the "world of waters," on which the earth floats as a boat; and below the "world of waters" are the seven Patalas or infernal regions, six of which are the abode of the Daityas or malignant spirits, and the seventh, which is divided into eight compartments, is the hell of sinners.

Mr. I. J. Schmidt has translated an extract from a Mongol work, giving an account of the creation ('Ssanang Ssetsen,' p. 302), according to which, nonentity or empty space is the original state of everything that exists. The creation of the world is in this account represented as proceeding from the "region of the second Dhyāna" (or the self-contemplation of the Deity), and as affected by the "region of the first Dhyāna" (or the divine will and agency?), which comprises the abodes of Brahmā, Vishnu, and Siva. A wind arises in this region, which, by blowing downwards, produces the abode of the superior order of spiritual beings; and in the same manner a succession of abodes of spirits gradually inferior is formed, till the winds reach the lowermost limbus of empty space, and there produce a condensation of air which becomes the germ of the material world. All these regions or abodes, with the exception only of the "region of the second Dhyāna," are subject to alternate production and dissolution.

Along with many other mythological conceptions, the Buddhas seem to have borrowed from the Brahmans their doctrine of the four yugas or periods of time into which a kalpa, or the duration of one existence of the world, is divided. These yugas they distinguish by the gradual decreasing length of men's lives in them. In the first yuga of the present kalpa, men lived 80,000 years; in the second, 10,000; in the third, 1,000; and in the present fourth yuga, which is again subdivided into four periods, the duration of men's lives will be successively diminished from 100 to seven years, and towards its termination the stature of men will only be the height of a thumb. (Hodgson, 'Transact. Roy. As. Soc.' vol. ii. p. 235.)

One of the essential differences of the Buddhists from the Brahmanical Hindus is the character which they attribute to their prophets or saints, and especially to the founder of their sect. Sākya Sinha,

according to the uniform belief of all his followers, was not, like Rāma or Krishna, an avatara, or incarnation of the Deity, but a mortal man, who by his sanctity and devotion attained the highest eminence, and after his death proceeded at once to the final re-union with Adi-Buddha. He had been preceded by six persons similar to him in holiness, whose names were Vipasya, Sikhi, Viswabhu, Kukuchhanda, Kānchana (or Ranaka Muni), and Kāsyapa: but nothing is told us of the deeds of these mythological beings, and they are even enumerated variously, the first three being sometimes omitted. Another saint of this description is expected to appear on earth when 5000 years shall have elapsed after the death of Sākya Sinha. The appearance of the latter was followed by a succession of Bodhisattvas, that is, mortals born perfectly virtuous, whose souls are no longer subject to the necessity of terrestrial existence, but who voluntarily descend to the earth in order to promote the welfare of mankind. These Bodhisattvas have gradually assumed the character of reappearances of Sākya Sinha himself, in which capacity the line is continued till the present day in the several Lamas of Tibet; for it is admitted that the reviviscence of the sage in more than one individual simultaneously involves no contradiction.

This dogma of a continued identity of person in the successive Lamas is strikingly illustrated by a passage in a letter addressed in 1774 by the Lama of Teshoo Loomboo to the Governor-general in India, in which he applied for the grant of a small piece of ground near Calcutta, stating as a motive for his request, "that although in the different periods of his reviviscence he had chosen many regions for the places of his birth, yet Bengal was the only country in which he had been born twice, for which reason he had a predilection for it beyond any other." (Turner's 'Embassy to Tibet,' pref. p. xv.)

The Buddhists reject entirely the authority of the Vedas, and the religious observances, sacrifices, and ceremonies which are prescribed in them and kept by the Hindus. They have no distinction of hereditary castes. Their priests are chosen from all classes of men: they are obliged to live in celibacy, but may resign their sacerdotal character, if they desire it, and are then permitted to marry. In Ceylon three orders of priests are distinguished: those of the highest order (who seem to be the only true Buddha priests in the island) are usually men of high birth and learning, and are supported at the principal temples called vihāras, most of which have been richly endowed with farms, &c. for their maintenance by the former monarchs of the country. A translation of some highly interesting inscriptions in which grants of this kind, and the conditions attached to them, are recorded, has been given by Mr. G. Turnour in the Ceylonese Almanac for 1834, p. 178, &c. All Buddha priests go bare-headed, and with their heads shaved; but to defend themselves from the sun they carry an umbrella made of the leaf of the palmyra-tree, and Knox mentions that they are permitted in Ceylon to wear this screen "with the broad end over their heads foremost, which none but the king does." In Ceylon they wear a yellow coat, gathered together about the waist and coming over the shoulder, and girt about with a belt of fine packthread. In the appendix to Symes's Embassy to Ava there is an account of the ceremonies used in the Birman empire at the consecration of a Buddhist priest. The candidate is reminded of four principal commandments, which require him to observe strict chastity, not to commit murder, not to steal, and not to practise sorcery, or to disgrace the priestly character by covetousness; and he must promise that he will procure his maintenance by perambulation and begging; that he will wear a particular kind of dress; that he will dwell in houses of a certain description, and that he will endeavour to turn to some use things thrown aside as useless by others, or to discover the medicinal powers of plants not previously employed. Buddhist priests are not forbidden the use of animal food, but they must not slaughter animals themselves. Convents for priests, as well as nunneries, exist in all countries where Buddhism has been introduced. Their processions and their forms of religious worship are described as being attended with much pomp and splendour, and well calculated to impose upon the multitude. The first Christian missionaries that proceeded to Tibet were surprised to find there, in the heart of Asia, monasteries, processions, festivals, a pontifical court, and several other ecclesiastical institutions resembling those of the Roman Catholic church; and many were induced by these similarities to consider Lamaism as a sort of degenerated Christianity. It should, however, be remembered that at the time when Buddhism was introduced into Tibet, somewhere about the middle of the 13th century, Nestorian Christians had ecclesiastical settlements in Tartary; that Italian and French messengers who visited the court of the Khans carried church ornaments and altars with them, and celebrated their worship in the presence of the Tartar princes; and that an Italian archbishop sent by Clement V. established his see at Karakorum, and erected a church in which divine service was performed with all the ceremonies usual in Europe. It is by no means improbable that the Lamas, whose court then began to assume a splendid exterior, should have adopted some of the forms of the Catholic service as they saw it celebrated by these foreigners, and that imitation should thus have co-operated in producing a similar mode in conducting the divine worship in two religions essentially foreign to each other, and this belief is accepted by M. Huc in his 'Souvenirs d'un Voyage dans la Tartarie, le Thibet, et la Chine pendant les années 1844, 1845, et 1846,' Paris, 1850.

BUDDING, an operation in horticulture, by means of which the branches of one kind are often made to grow upon the stem of another kind. It is stated in the article BUD [NAT. HIST. DIV.], that this organ has the power of growing when separated from the mother-plant. Not only will it grow, but it will emit roots, form a stem, and become in time a new individual in all respects similar to its parent, retaining all the special peculiarities of the latter. In this respect it differs from a seed, which in general is not capable of doing more than propagating a species, without any power of preserving, unless accidentally, the peculiarities of the individual from which it sprang.

Gardeners have availed themselves of this property in leaf-buds for the purpose of artificial propagation, either by planting the separated buds in earth, or by introducing them into the branches of other plants. The former is called propagation by eyes; the latter only is technically named budding.

Budding is usually executed thus: With a very sharp knife a fully formed bud, and the leaf to which it is axillary, are pared off the branch, along with about half an inch of bark adhering to them at the upper end, and an inch and a-half at the lower end. By holding the leaf firmly between the finger and thumb of the left hand, with the wounded side of the paring uppermost, the operator is able to disengage from the bark the small slip of wood which adheres to it, and by a jerk to snap it off the paring, leaving nothing but the cellular centre of the bud adhering to the bark. This done, he makes in the branch to be operated on, one incision transversely through its bark, and another longitudinally at right angles to the first and in a direction downwards, so that the two together resemble the figure of the letter T. He then, with a flat ivory blade, lifts up the bark on each side of the longitudinal incision, so as to separate it from the wood, and inserts beneath it the prepared bud, which is gently pushed downwards till the bud itself is a little below the transverse line. This done, a ligature of bass is carried round the stem so as to bind the bud firmly to the new wood on which it is placed. If the operation is well performed, the bud will thus be fixed on a new plant in the same position as it occupied on the branch from which it was taken; the mouths of the medullary rays of its bark will unite with those of the wood of the stranger plant, it will be kept in contact with a continual supply of food oozing out of the alburnum on which it is placed, it will absorb that food, and soon accustom itself to its new position. Then, when the growing season arrives it will be stimulated by light and warmth to attract sap from the wood to which it has adhered, it will push forth new wood of its own over that which it touches, and thus will form as intimate a union with its stock as it would have formed with its parent plant. In order to enable the latter to do this, it is customary to head down budded branches to within a few inches of the buds, so as to compel the sap which oozes from the roots to expend itself upon the former; a few natural buds near the artificial bud are allowed to push sufficiently to attract the sap to their neighbourhood, and are then destroyed; when the stranger bud has pushed to the length of a few inches, it is tied to the stem so as to be secured from being broken off by accident; and finally, when it is quite secure, that small portion of the stem of the stock which had been left above the bud in the first instance is cut away, and the branches produced by the bud become the head of the new tree.

Such is the general nature of budding, but like all other operations it can only be well performed after some experience. It may be varied within certain limits, and there are in fact a few other modes, such as *reversed-budding* and *scallop-budding*, which are occasionally practised (see Loudon's 'Encycl. of Horticulture,' new edition, p. 656); but that here described is the most common and the best. Roses, plums, peaches, nectarines, cherries, and many other plants are chiefly propagated thus, and there is no theoretical reason why it should not be extended to all species. In practice, however, it is occasionally found impracticable, as in heaths, in vines, &c., owing to specific causes, which vary in different instances.

Budding is usually performed in the months of July and August, because at that season the bark separates freely from the wood, and the young buds are fully formed; but whenever the two latter conditions can be satisfied, the operation may take place equally well.

It must, however, be observed, that the bud of one plant can only be made to grow upon the wood of another when both bud and stock are nearly related botanically. Thus, the orange tree will not bud on the pomegranate, as is supposed by the ill-informed. Roses will bud upon roses, but not upon currants; apples will bud upon pears or thorns, pears upon medlars or quinces, and apricots upon plums, because all these species are closely related; but an apple will not bud upon a plum or a peach, because, although they are allied to a certain degree, yet their consanguinity is not sufficiently strong.

BUDE LIGHT. This, together with many other modes of illumination for domestic, scientific, and manufacturing purposes, will be described under LIGHTS, ARTIFICIAL.

BUFFOON, a jester; the name is said to be derived from "buffa," a word of the corrupt latinity of the middle ages, synonymous with *alapa*, that is, a slap on the cheek. *Buffe* and *Buffet* in the old French, and *Bofetada* in Spanish, were used in the same sense. Mountebanks and clowns in the farces used frequently to swell their cheeks with wind and then give each other a slap which produced a noise, to the amusement of the spectators. Hence are derived the word *Buffones* in

Latin, the French *Bouffons* and the Italian *Buffoni* (Ducange). *Buffare*, or *sbuffare* in Italian, means to puff the wind through the mouth. The English word buffoon is now generally used in a contemptuous sense. The Italians have two distinct words, *Buffo* and *Buffone*. *Buffo* is a theatrical term: opera buffa, comedia buffa, is a burlesque play, in contradistinction to opera seria and comedia di carattere, or serious comedy. The buffo is one of the principal characters in those plays, corresponding to the English clown; in an opera there are often two, primo buffo and secondo buffo. *Buffone* in Italian means a funny ludicrous fellow, but not always in a contemptuous sense. *Bouffon* in French and *buffoon* in English have been occasionally used as synonymous with king's fool, a well-known character at courts in former times.

BUILDING, or the art of constructing edifices, is defined by some writers as practical, in contradistinction to theoretical, architecture; but, without a previous explanation of the meaning of the term architecture, such a definition is imperfect, since, although building is necessarily included or involved in the execution of all architectural works, many of the works produced by the builder have either no claim at all, or a claim by no means generally admitted, to be considered architectural works. In the practice of civil architecture, the builder comes between the architect who designs the work and the artisans who execute it; and, in a commercial point of view, between the party by whom the capital is provided on the one hand, and the merchants and manufacturers who provide the necessary materials, and the workmen whose office it is to shape and unite them, on the other. For the temporary employment of his own capital and the exercise of his directing skill, he is usually remunerated by charging his employer for labour and materials at a higher rate than he has paid himself; and, for the mutual security of all parties, he generally works by contract, either undertaking to execute the building, with all contingent works, for a given gross sum, which is termed a lumping contract, or agreeing to perform the whole work at certain specified rates per yard, rod, foot, &c., according to the nature of the work, the quantities being measured according to established rules.

An article upon the multifarious operations connected with building would not only require more space than is consistent with the plan of this work, but would also involve the repetition of much information already given under various heads. Such a general treatise is supplied in the long and elaborate article 'Building,' in the 'Encyclopædia Britannica,' contributed by Mr. Hosking; a treatise which may be consulted with advantage by readers who wish to go very fully into the subject. Here we propose to do little more than give such an outline as may enable the reader to turn readily to those portions of the work in which the various branches of the general subject are treated of.

Of the distinction between building, properly so called, and architecture, some account is given, together with remarks on ancient styles of building, in the article ARCHITECTURE; and under HOUSE, the subject of domestic architecture, which it is all-important for a builder to be well acquainted with, is treated at some length. From the last-mentioned article it will be evident that the attention of the builder should be directed rather to matters of utility and comfort than to such as relate to ornament; although as many houses are erected without the aid of a professed architect, it is desirable that he should be so far acquainted with the principles of architectural design as to avoid unpleasant proportions and incongruity of ornament. Where the choice of site remains with himself, he should avoid a low and damp situation, and also a situation exposed to cold winds. A good supply of water to the house, and sufficient fall to ensure perfect drainage, are essential; and as a general rule, the advantage of southern and western frontages should be secured as much as possible. The direction of the prevalent winds is a point to be carefully considered, in order that the openings of doors and windows may be so arranged as to avoid draughts and smoky chimneys, which are not unfrequently occasioned by want of due attention to this matter. [SMOKE.] Such points being duly considered, drawings of the intended building, showing not only its exterior form, but also its interior arrangements and the substance of its walls and partitions, as explained under DESIGN, ARCHITECTURAL, are prepared; after which the actual construction commences by the preparation of a firm foundation for the structure, as described under FOUNDATION. The excavation formed for the foundation should be executed with the utmost care, and the level must be produced by the removal of earth until an even surface is obtained; the production of a level by filling up hollows with loose materials is extremely hazardous. For the mode of laying foundations under water see COFFERDAM.

The articles BRICKWORK and MORTAR contain information on the construction of brick walls; but the Metropolitan Buildings Act (18 & 19 Vict. c. 122), contains provisions, particularly in the schedules, which must be carefully attended to by every builder.

The various modes of bonding brick walls are sufficiently described in BRICKWORK; but these relate simply to the mode of arranging the separate bricks or component parts into a solid and cohesive wall or mass of brickwork. Much more than this, however, is required in building the walls of a house, in order to prevent, as much as possible, their strength from being impaired by the necessary openings for doors and windows, and to afford the means required for connecting the door and window frames, floors, partitions, and other woodwork, with

the shell of the structure. The effect of apertures in a wall is counteracted by the introduction of inverts, or inverted arches, in the portion of wall beneath them, and of discharging arches, which may either be left visible or not, over them. The fixing of door and window frames, and other small woodwork, is provided for by the insertion in the wall of *wood-bricks*, or blocks of seasoned wood resembling bricks in form and size. *Lintels* are bars of wood inserted, in lieu of arches, over the apertures of doors and windows; but they should always be surmounted by discharging arches abutting upon the solid brickwork beyond the ends of the lintel, which, in such a case, may be made to tail into the wall to a very short distance only beyond the sides of the aperture. Where, however, there is to be no discharging arch over the lintel, it should be of sufficient length to tail considerably into the wall, and its ends should rest upon transverse templates or wood-bricks built into the wall. *Templates* are pieces of timber often three or four feet long, which are let into the wall after the manner of wood-bricks, either for the purpose of fastening to, or of supporting the ends of beams let into the wall, and distributing their pressure over a considerable space. Discharging arches should be turned over these, and over the ends of beams, so that their shrinkage, or even their decay or destruction by fire, should not be sufficient to affect the stability and cohesion of the wall. Some floors are so framed together that they may be connected with the walls by a few principal beams, the ends of which rest upon templates; but more usually the ends of the joists rest upon long pieces of timber called *wall-plates*, which are let into the brickwork, and serve to distribute the weight equally. *Bond-timbers* are occasionally inserted with a special view to the distribution of strain, but their liability to swelling and shrinking, as well as their perishable and combustible character, render it desirable to bond the structure as perfectly as possible without them. Timbers should, in all cases, be kept clear of the chimney flues, or, if this be impossible, should be guarded with iron so as to prevent the possibility of a spark coming in contact with them. The various plans which have been introduced of late years for securing timber from the ravages of dry-rot, and rendering it incombustible, greatly lessen the risk of employing it in walls. [TIMBER, PRESERVATION OF.] The variations of size occasioned by changes of temperature render the combination of iron with brickwork even more hazardous than the use of timber, though the employment of straps of hoop-iron laid in the mortar between the courses of bricks is found advantageous under certain circumstances. An instance of its employment in the construction of arches without centering is mentioned under SCAFFOLDING. The brittleness of cast-iron renders it very unfit for use where unequal settlement may occur. The construction of efficient drains should be attended to in an early stage of the building. This subject is fully treated under SEWERS, and it is only necessary here to observe, that in order to increase the current and prevent the deposit of sediment, all drains should be concave at the bottom, and that where they pass through houses, or in any case in which it is probable that they may have to be opened, it is desirable to make the top consist of flat paving-stones or tiles, laid in cement; as a circular, barrel, or, as it is sometimes called, a gun-barrel drain, unless its fall be very considerable, will be likely to involve much trouble and expense in opening and cleaning. Where the drain is straight, and short enough to be raked, this matter is not of consequence. It is a usual and convenient plan to conduct the drain under a doorway, between the sill and the invert; but when this cannot be done, an arched opening, called a bull's-eye, must be made in the wall where it passes through. In addition to the air-traps which, as described under SEWERS, should always be placed at the entrance of drains, a very simple trap may be formed at any convenient point in their course, by sinking a small well a few inches below the bottom of the drain, and building in with the brickwork of the drain a flat piece of flagstone in such a manner as to form a dipping-valve resembling that shown in SEWERS, so that no water can escape until the well is filled, and no air can pass the trap unless the well becomes, by evaporation, so dry as to allow it to pass under the edge of the dipping-valve.

As the erection proceeds, contrivances for supporting the workmen and materials are required, of which an account is given under SCAFFOLDING. In the basement story of a building, the partition walls, as well as the external and side or party walls of a house are usually formed wholly of brickwork, but in the upper stories they are generally of lath and plaster, on a framed and trussed timber foundation, or of what is technically called *brick nogging*, which consists of a framework of quartering, similar to that used for lath and plaster, but having the intermediate spaces between the timbers filled up with brickwork, thus forming a wall either $4\frac{1}{2}$ or 3 inches thick, according to whether the bricks are laid flat or on edge. Though strengthened by the upright quarterings or timbers, the brickwork, being so thin, should be strengthened or bonded further by the introduction, at intervals of not more than six courses, of horizontal bars of wood called *interties*, or *nogging-pieces*, skew-nailed at each end to the quarterings. Some builders, in lieu of brick nogging, use half-brick, or $4\frac{1}{2}$ inch, walls carefully built in cement, and strengthened with iron hooping, a plan which has the advantage of greater security from fire. Such partitions also check, more effectually than those in which much timber is introduced, the transmission of sound from one room to another. The joints of brickwork in internal walls, and in such external walls as are to be covered

with plaster, stucco, or cement, are left rough, with the mortar projecting from the joints, because the inequality of surface thus produced causes the plaster to adhere better; but in such external walls as are to be exposed to view, the superfluous mortar is removed, and each joint is *drawn*, by applying the point of the trowel so as to flatten the joint, or rather to leave it slightly concave. The use of thick beds of mortar between the bricks is not only injurious from the settlement thereby occasioned, but also because the compression of the mortar causes it to bulge out at the joints, and so to counteract the effect of drawing with the trowel. The joints, being thus rendered convex instead of concave, catch and absorb the rain which trickles down the wall, and when a frost comes this absorbed moisture freezes, and occasions the mortar to crumble away, thus involving the necessity of *pointing*, or filling in the joints with new mortar, to preserve the wall. To do this, the old mortar must be scraped out to the depth of three-eighths of an inch, or further if needful, and the joints must be thoroughly cleaned and moistened before inserting the new mortar, which should be of the best quality. Mortar for this purpose is commonly mixed with forge ashes, which give it a bluish tinge, and render it better fit to resist injury from weather. Cement is sometimes used for the purpose in lieu of mortar. If the work be required to be very neat, each joint is finished with a narrow line or parallel ridge of fine white putty or mortar, made principally of bone-lime. In the application of this kind of pointing, which is termed *tuckpointing*, to an old wall it is usual to wash and colour the whole surface of the brickwork; and when, by the carelessness of the bricklayer, the vertical joints which should come in a line over each other, technically called the *perpends*, have not been properly attended to, the misplaced joints may be filled up with brick-coloured putty, and false joints made in the proper places. Mortar used for the *pargetting*, or internal plastering, of brick chimney flues is mixed with a little cow-dung, to prevent its peeling off from the heat. The top of a brick-wall, whenever it is not covered by the roof, must be protected by coping [COPING], which in single-brick walls is often formed simply by a row of bricks set on edge in cement across the wall, and called a *barge-course*, a name which is also given, with more propriety, to the projection of a roof over a gable-end. [BARGE-COURSE.] This kind of coping is very imperfect, because, as it has no projection or inclination, it does not throw off the water. It may be improved both in appearance and efficiency by laying underneath the barge-course two double courses of plain tiles, with their joints broken, and their edges projecting about an inch and a half on each side of the wall, or by a similar application of paving tiles. Stone coping, however, which can be made of any width, and properly sloped or weathered and throated, is far better. For ornamental brickwork proper coping-bricks are made, which if well set in fine mortar or cement may be equally efficient with stone, and have a better architectural character. It may be remarked, generally, that brick walls often suffer injury in consequence of the insufficient projection of copings and cornices, which ought to throw off water as much as possible from the face of the wall.

The established mode of measuring brickwork is explained under BRICKWORK. Brick and tile paving, which are noticed under FLOOR, are measured by the superficial yard of 9 feet, and tiling, for which see ROOF and TILE, by the *square* of 100 superficial feet.

Of the use of stone in building some account is given under MASONRY, ASHLER, and RUSTICATED WORK. Rubble-work is more difficult to execute well than building with cut or squared stones, since there is great danger of trusting too much to the mortar. Unwrought stones, however irregular in shape, ought to be so laid together that the wall would stand if laid to a considerable height without mortar. It is of course desirable to give the outside of a rubble wall as neat an appearance as possible; but care must be taken in doing so to bond the facing stones as thoroughly as possible with the centre of the wall, and not for the sake of show, to expose the bed of the stone, or the flat surface formed by its stratification, in the face of the wall, as a stone so applied cannot be firmly bonded into the wall, and its flat surface is far more liable to injury from the action of the atmosphere than a surface cut at right angles with its plane of stratification. It is better to bond the wall by means of many stones extending partly through its thickness, alternately from each side, than to use a few thorough stones, or stones reaching completely from face to face, and yet leave the greater part of the wall like two shells enclosing an irregular core of coarse rubble. Stone copings and some other kinds of stone-work are frequently cramped together with fastenings of iron or copper, run in with melted lead; but unless these metal fastenings, especially those of iron, can be thoroughly secured from the influence of the atmosphere, they are liable, from oxidation and the effect of changes of temperature, to produce much harm, and therefore it is better, if possible, to use tenons, dowels, joggles, or dowels of stone or wood, protecting them also from the weather. The principal purposes for which stone is introduced in brick buildings are enumerated under MASONRY, to which we need only add that the setting of stone window and door-sills is usually delayed as long as possible, to give the brickwork time to settle, because a very slight inequality in the settlement would cause them to break, being long and thin. The brittleness of stone, indeed, renders it always inadvisable to use it in pieces of great length of bearing, and very important to make the joints perfectly even. In the jointing of columns, for example, the

ends of the adjacent stones must not be worked hollow, with a view to making the joint perfect at the edges. A better plan is to work them flat, and insert a thin sheet of lead between them, cut a little smaller than the column itself, thereby leaving a small open joint all round, to be filled up with fine putty. Stone walls are usually measured by the perch of 21 superficial feet, of an assumed standard thickness of 18 inches, and therefore containing $31\frac{1}{2}$ cubic feet; but sometimes the rod is used as a measure, as in brickwork, assuming however a thickness of 18 instead of $13\frac{1}{2}$ inches.

Besides brick and stone, other materials are occasionally employed for the construction of walls, of which we may allude to flints and earth. Houses built of flints, which can only be used to advantage in certain localities where that material abounds, necessarily depend much for the cohesion of their walls upon the strength of the mortar, and on the judicious introduction of bonding courses of brick or larger stone, and of quoins or angles of the same. When well executed, the appearance of flint buildings is far from displeasing, and by a little management of the contrast afforded by the white outside and black centre of the flints may be made absolutely ornamental. Building with compressed earth, or building *en Pisé*, is a very cheap, simple, and when properly managed, durable mode of building, which has been long and extensively practised in some parts of France, especially in the neighbourhood of Lyon, and has been adopted in this country not only as a substitute for the rude plan of constructing cabins with mud tempered with straw, and held together by wattles and timber framework, but also in lieu of regular brickwork. In vol. xxvii. of the 'Transactions' of the Society of Arts, pp. 185-197, is a minute description, illustrated by a plate of the apparatus employed, of an improved mode of executing this kind of work, invented by Mr. Robert Salmon, of Woburn. The foundations, and the walls to a short distance above the level of the ground, are built of stone or brick, but all the upper part of the walls consists simply of earth, beaten or rammed into a compact mass between two boards, which are fastened in such a position that their inner surfaces correspond with the faces of the wall. The work proceeds in courses, and each course in portions of convenient length; and the boards, which serve as a mould, are so connected by bolts that they may be readily separated from one another, and from the completed portion of wall, and put together again in the required position for forming another portion of wall. The earth is thrown in in small quantities, so that every portion may be very completely beaten, and as it is thrown in, a little is drawn away from the surface of the mould, and its place supplied by a facing composition, consisting of about one-fourth lime and three-fourths of the earth used for walling, mixed together with water and slaked like mortar, but allowed to dry and pulverise before it is rammed in. This facing composition, which is applied about an inch thick, forms a cement-like face to the wall, and it preserves the earth from the access of moisture. When the surface of one course of earth has become hard before another is added to it, a little thick grout of lime and earth is added to facilitate the adhesion of the new and old work. Mr. Salmon observes that the earth for this work "should be neither sand nor clay, but partaking of both." "Clay," he adds, "is particularly objectionable, as is also chalk or calcareous earth of any sort. Sand is also not proper, unless accompanied with some binding quality: the bolder and coarser the sort of earth the better. When used, it should retain no more moisture than just to make it adhere together under the pressure of the thumb and finger." Earths containing a mixture of grit or fine gravel he considers generally the best. Bond-timbers, wall-plates, and all other pieces of wood inserted in the walls, are kept as thin as may be, to avoid settlement from shrinkage; and doorways and openings for windows may be conveniently formed by the insertion of temporary frames of stout planking, against which the earth is rammed as against the mould. In this mode of building labour forms the most important item of cost. At Woburn, with labourers at 1s. 10d. per diem, Mr. Salmon found the expense of a 16-inch wall to be about 2s. 8d. per superficial yard if faced and finished on one side only, and 3s. 4d. per yard if faced and finished on both sides; while the value of a superficial yard of brickwork, 14 inches thick, would have been more than 10s. at the same time and place. The walls may be finished externally by lime-washing, and, if intended to look very neat, by wetting and rubbing the surface with a plasterer's float, until it is smooth and even. A full account of the French mode of executing this kind of building is given in the sixteenth volume of the 'Dictionnaire Technologique' (8vo, Paris, 1829), art. 'Pisai, Pisé,' and in a briefer notice in the fourth volume of the 'Dictionnaire de l'Industrie' (8vo, Paris, 1795), article 'Murs en Terre,' and in some remarks respecting the meaning of the term *Pisé*, or, as it is sometimes written, *Pisé*. If the projection of the roofs be sufficient, and other precautions be taken to keep the walls dry, buildings of this character may be safely constructed of two or three stories in height, and they will prove very durable, many such buildings in France having stood more than a century without any symptom of decay.

Respecting the means of protecting walls from damp, whether arising from the foundation or not, some information is given under ASPHALTE. Double walls, in which a space is left between the external brick or stone wall, and the lining of the room of whatever kind it may be, are sometimes resorted to as a means of preventing the passage of damp, and a simple mode of producing the same effect,

which answers well when great strength is not required, is accomplished by the use of bricks laid on their edges instead of their flat sides. In a single brick or 9-inch wall of the ordinary construction there are no hollow spaces, because, the bricks being laid flat, the width of two stretchers, being $4\frac{1}{2}$ inches each, is exactly equal to the length of the headers, that is to say, 9 inches. If, however, the bricks be laid on edge, but otherwise disposed in the same way, while the headers are, of course, of the same length, the width of the stretchers will be only 3 inches each, so that if they are laid to the face of the wall they will leave an intermediate space of 3 inches. Of course a less number of bricks will be required to produce an equal surface of wall by this than by the ordinary mode of laying.

Of the various departments of building relating to CARPENTRY and JOINERY brief notices will be given under those heads, with references to the various articles relating to them. Here it is only needful to observe that the portions of a building supplied by the carpenter should be so contrived as to strengthen and bind together the whole structure. The ROOF, especially, of which a full account is given under that head, should contribute greatly to the solidity of the building, as well as answer the primary purpose of a covering. In London houses, owing to the great value of space, sleeping-rooms are very often formed in roofs; and in certain cases, when the ridge of the roof is made parallel to the front of the house in order to secure as much internal space as possible, the front gutter is connected with that at the back of the house by a covered trough passing through the apartment formed in the roof, so that although the fall of water from the roof may be equal towards the front and back, the pipes for conducting the water to the ground may be confined to the back of the house. For the external covering of walls in which the brickwork is coated by a stone-like composition, see STUCCO; and for the lining of walls, the formation of ceilings, &c., see PLASTERING. Internal decorations are treated of under PAINTING, HOUSE, and PAPER HANGINGS. More specific information respecting the various parts of a building will be found in such articles as STAIRCASE, DOOR, WINDOW, ARCH, DOME, and CHIMNEY; and under FIREPROOF BUILDINGS, will be noticed some important deviations from the ordinary mode of building, in order to diminish the risk of fire.

BUILDING, ACTS FOR REGULATING. Provisions for regulating the construction of buildings are generally introduced into Acts for the improvement of towns. To permit houses of wood or thatched roofs in confined and crowded streets would be to sacrifice the public welfare to the caprice or convenience of individuals. There is no general measure ensuring uniformity of regulations for buildings throughout the country. In the session of 1841 the Marquis of Normanby, then a member of the government, brought in a bill "for the better Drainage and Improvement of Buildings in large Towns and Villages," but it did not pass; and a bill of a similar nature was unsuccessful in the session of the following year; and it was not until the Public Health Act, 1848 (11 & 12 Vict. c. 63), that a general provision was made for controlling the sewerage and drainage of towns. In the session of 1844, however, an act was passed (7 & 8 Vict. c. 84), entitled "An Act for Regulating the Construction and the Use of Buildings in the Metropolis and its Neighbourhood;" and this measure, though applicable only to London, was an important step towards improving the condition of large towns. It was amended two years afterwards, but was (with certain exceptions hereafter noticed) repealed by the Metropolis Building Act, 1855 (18 & 19 Vict. c. 122). London has had Building Acts ever since the reign of Queen Anne; but their object was chiefly to enforce regulations calculated to check the spread of fire. A Building Act, commonly called Sir Robert Taylor's Act (14 Geo. III. c. 78), was passed in 1774, "for the further and better regulation of buildings and party walls, and for the more effectually preventing mischiefs by fire." It extended to the cities of London and Westminster, and their liberties and other places within the bills of mortality, and to the parishes of St. Marylebone, Paddington, St. Pancras, and St. Luke's, Chelsea. The administration of the act was confided to district surveyors, each of whom had independent authority within his own district; but the magistrate at the nearest police-office might enforce or not, at his own discretion, the decisions of the surveyor. The technical regulations of this Act were many of them, generally speaking, of so impracticable a nature that their evasion was connived at by the officers appointed to superintend the execution of the law, and it did nothing to discourage the erection of imperfect buildings in districts which have become a part of the metropolis since it was passed.

The objects of the more recent legislation may be gathered from the preamble to the Act of 1844, which was as follows:—"Whereas by the several Acts mentioned in schedule (A.) * to this Act annexed provisions are made for regulating the construction of buildings in the metropolis, and the neighbourhood thereof, within certain limits therein set forth; but forasmuch as buildings have since been extended in nearly continuous lines or streets far beyond such limits, so that they do not now include all the places to which the provisions of such Acts, according to the purposes thereof, ought to apply, and

* These Acts are 14 Geo. III. c. 78, partly repealed; 50 Geo. III. c. 75, wholly repealed; and 3 & 4 Vict. c. 85, repealed so far as it relates to flues and chimneys.

moreover such provisions require alteration and amendment, it is expedient to extend such limits, and otherwise to amend such Acts: and forasmuch as in many parts of the metropolis and the neighbourhood thereof, the drainage of the houses is so imperfect as to endanger the health of the inhabitants, it is expedient to make provision for facilitating and promoting the improvement of such drainage; and forasmuch as by reason of the narrowness of streets, lanes, and alleys, and the want of a thoroughfare in many places, the due ventilation of crowded neighbourhoods is often impeded, and the health of the inhabitants thereby endangered, and from the close contiguity of the opposite houses the risk of accident by fire is extended, it is expedient to make provision with regard to the streets and other ways of the metropolis for securing a sufficient width thereof; and forasmuch as many buildings and parts of buildings unfit for dwellings are used for that purpose, whereby disease is engendered, fostered, and propagated, it is expedient to discourage and prohibit such use thereof: and forasmuch as by the carrying on in populous neighbourhoods of certain works, in which materials of an explosive or inflammable kind are used, the risk of accidents arising from such works is much increased, it is expedient to regulate not only the construction of the buildings in which such dangerous works are carried on, but also to provide for the same being carried on in buildings at safe distances from other buildings which are used either for habitation or for trade in populous neighbourhoods; and forasmuch as by the carrying on of certain works of a noisome kind, or in which deleterious materials are used, or deleterious products are created, the health and comfort of the inhabitants are extensively impaired and endangered, it is expedient to make provision for the adoption of all such expedients as either have been or shall be devised for carrying on such businesses, so as to render them as little noisome or deleterious as possible to the inhabitants of the neighbourhood; and if there be no such expedients, or if such expedients be not available in a sufficient degree, then for the carrying on of such noisome and unwholesome businesses at safer distances from other buildings used for habitation; and forasmuch as great diversity of practice has obtained among the officers appointed in pursuance of the said Acts to superintend the execution thereof in the several districts to which such Acts apply, and the means at present provided for determining the numerous matters in question which constantly arise tend to promote such diversity, to increase the expense, and to retard the operations of persons engaged in building, it is expedient to make further provision for regulating the office of surveyor of such several districts, and to provide for the appointment of officers to superintend the execution of this Act throughout all the districts to which it is to apply, and also to determine sundry matters in question incident thereto, as well as to exercise in certain cases, and under certain checks and control, a discretion in the relaxation of the fixed rules, where the strict observance thereof is impracticable, or would defeat the object of this Act, or would needlessly affect with injury the course and operation of this branch of business; now for all the several purposes above mentioned, and for the purpose of consolidating the provisions of the law relating to the construction and the use of buildings in the metropolis and its neighbourhood, be it enacted," &c.

By the present Act, the 18 & 19 Vict. c. 122, every building and work done upon it is subject to the supervision of a district surveyor, who is appointed and paid by the Metropolitan Board of Works, under the Metropolitan Local Management Act (18 & 19 Vict. c. 120), the area of that Act being also the limits of the Building Act, comprising the parishes of St. Marylebone; St. Pancras; Lambeth; St. George's, Hanover Square; St. Mary, Islington; St. Leonard, Shoreditch; Paddington; St. Matthew, Bethnal Green; St. Mary, Newington, Surrey; Camberwell; St. James, Westminster; St. James and St. John, Clerkenwell; Chelsea; Kensington (St. Mary Abbot); St. Luke, Middlesex; St. George the Martyr, Southwark; Bermondsey; St. George in the East; St. Martin in the Fields; Hamlet of Mile End Old Town; Woolwich; Rotherhithe; and St. John, Hampstead; with a power to the Queen in Council to extend the area under certain circumstances. The first part of the Act with its schedules relates to the "regulation and supervision of buildings, including alterations and additions, and provides for the structure and thickness of walls and their composition, roof, chimneys, accesses and stairs, rooms, passages, projections, and a variety of other matters securing ventilation, open spaces," &c. Part II. of the Act relates to "dangerous structures;" Part III., to "party structures;" Part IV. contains miscellaneous provisions as to the payment of expenses by owners, legal proceedings, &c.

The provisions of the previous Act (7 & 8 Vict. c. 84), for the restraint and eventual removal from populous neighbourhoods of trades which are dangerous, noxious, or offensive, are retained. By these sections businesses dangerous as to fire must not be nearer than fifty feet to other buildings; and new businesses of this character must be forty feet from public ways. Persons cannot establish or newly carry on any such businesses within fifty feet of other buildings or forty feet from public ways; and all such businesses carried on within the distances limited by the Act must be given up twenty years after the passing of the Act. A penalty of 50*l.* is incurred for erecting buildings in the neighbourhood of any such businesses, and 50*l.* per day for carrying on businesses of a dangerous kind contrary to the Act. The persons offending may be imprisoned for six months if the penalty

be not paid. The businesses of a blood-boiler, bone-boiler, fell-monger, slaughterer of cattle, sheep, or horses, soap-boiler, tallow-melter, tripe-boiler, and any other business offensive or noxious, are subject to similar regulations as those deemed dangerous as to fire, and are to be discontinued at the end of thirty years after the passing of the Act. Trades deemed nuisances may be removed by purchase at the public cost on memorial by two-thirds of the inhabitants, and on the issue of an Order in Council. Public gas-works, distilleries, and other works under the survey of the Excise are exempted from the operation of some of these provisions.

"The Local Government Act, 1858" (21 & 22 Vict. c. 98), amending the Public Health Act, 1848, empowers every local board to make bye laws with respect to the following matters: 1, with respect to the level, width, and construction of new streets, and the provisions for the sewerage thereof; 2, with respect to the structure of walls of new buildings, for securing stability and the prevention of fires; 3, with respect to the sufficiency of the space about buildings to secure a free circulation of air, and with respect to the ventilation of buildings; 4, with respect to the drainage of buildings, to water-closets, privies, ash-pits, and cess-pools in connection with buildings, and to the closing of buildings, or parts of buildings, unfit for human habitation, and to the prohibition of their use for such habitation. The local board may also prescribe the line in which houses shall be rebuilt, making compensation to the owners for any loss or damage sustained in consequence of the building being set back. These powers are independent of various provisions for the prevention and removal of nuisances.

Scotland is under the operation of a peculiar statute passed in 1855, the 'Act to facilitate the Erection of Dwelling Houses for the Working Classes of Scotland.' Under certain conditions, and with the consent of the county and burgh authorities, four or more persons may unite for the purpose of building workmen's dwellings. They are to act as a joint-stock company with limited liability; and may appropriate the profits of their enterprise in the form of dividends. To ensure the carrying out of plans conducive to the attainment of the proposed end, all the proceedings of these companies are controlled to a certain extent by the sheriffs of counties, or the deans of burgh guilds. Each separate dwelling is to constitute a distinct lot, to consist of not less than two, nor more than five rooms with fire-places; each such lot or dwelling is not to be divided, but is to be held or transferred as an undivided whole. One of the most remarkable clauses in the Act is to this effect: "If any houses have fallen into a dilapidated or deserted state, and if a building company calls the attention of the authorities to this fact, the authorities may order the owner to rebuild or repair the houses in a proper way; and if he neglect to do so within three months the authorities may compel him to sell the property to the company for the purpose of being placed by them in proper condition, and at a price determined by means pointed out in the Act."

It may be here mentioned that the Building Societies, of which so large a number now exist in England, are based on the fact that the average rental of well-let houses is much higher than the average rate of interest on a given amount of capital. A man may in ten years pay as much money in the form of rental as the house costs to build. Hence the plan of *lending* him the money, at 5 per cent. interest, wherewith to build a house for himself; by paying a little more than the ordinary annual rental for a house of similar kind, he may in a few years pay off the whole of the debt, and become real owner of the house he lives in. The principle is probably a sound one; but it requires honesty and judgment on the part of the managers of the society. In some cases it has led to a species of speculation, not far removed from gambling.

BUILDING STONE. [STONE FOR BUILDINGS.]

BUL. The ancient name of a Jewish month, which is now called Marchesvan, or by abbreviation Chesvan. It was the eighth month, when the year began in spring, but after the transfer of New Year's day to autumn it became the second month; and in consequence of the variation of the lunar year, it may begin as early as the first week of October, or as late as the same period of November. The word is written בּוּל in Hebrew, and Βααλ, Βουαλ, or Βουλ, in Greek; and is derived from the verb נָפַל *to fall*; the name was probably given from the season of the year when it occurred, as in our popular term "the Fall." This appears preferable to the usual explanation, "the rainy;" a passage in Isaiah, ch. xl. v. 7 8, נָפַל צִיץ, "the flower fadeth," shows the precise kind of fall usually expressed by the verb; and moreover, this can hardly be called the rainy season in Palestine.

The name Bul is one of three which occur only in a very limited portion of the first book of Kings: Bul, in ch. vi. v. 38; Zif, in the same chapter, v. 1 and 37; and Ethanin, in ch. viii. v. 2. As these names, together with Abib, are the only ones in any part of the Bible written before the Captivity, while everywhere else months are designated by their numbers only, and as all these four terms have meanings which may relate to the seasons, it has been thought likely that they were merely such appellatives as we use when we say foggy month, or rainy month; but the very same words, *be yerach bul*, or "in the month of Bul," as we have in 1 Kings, vi. 38, above-mentioned, are found in the inscription upon the sarcophagus of King Ashmunezer, dug up in January, 1855, about a mile from Sidon, which proves its

use as a name; and it is curious, though possibly an accidental coincidence merely, that the second month in the ancient Assyrian calendars from Nineveh, now in the British Museum, which there are independent reasons for believing to correspond with the month under consideration, is written generally  a character which was certainly read *ul* or *val*. Sometimes the angular stroke at the left of the character was doubled, and sometimes omitted, but the sound was probably the same in all.

The names of the Jewish months now in use, include neither of the four above-mentioned; and any account of the fasts and festivals connected with these months will be given under their ordinary names.

BULIMIA (*βουλμία*), canine appetite, insatiable desire for food. The statement of the quantities of food consumed by some persons labouring under this disease is scarcely credible, yet it rests on testimony the veracity of which there is no reason to question. In the third volume of the 'Medical and Physical Journal' an account is given, by Dr. Cochrane of Liverpool, of a man placed under his own personal inspection, who, in one day, consumed of raw cow's udder, 4 lb., raw beef 10 lbs., candles 2 lb., in all 16 lb., besides 5 bottles of porter. M. Percy, a surgeon-in-chief to the French army, made a report to the National Institute of the case of a soldier who was in the constant habit of devouring enormous quantities of broken victuals, basketsful of fruits, and even living animals; the details given of the quality as well as of the quantity of articles consumed by this man, without ever satisfying his ravenous appetite, are too disgusting to be related. Dr. Copland gives an account of two cases of this disease, which occurred in his own practice in children, one seven years of age and the other nine. 'In both these, but in the younger especially, the quantity of food devoured was astonishing. Everything that could be laid hold of, even in its raw state, was seized upon most greedily. Besides other articles an uncooked rabbit, half a pound of candles, and some butter, were taken at one time. The mother stated that this little girl, who was apparently in good health otherwise, took more food, if she could possibly obtain it, than the rest of her family, consisting of six besides herself. In both this and the other case the digestion seemed to be good. A nauseous smell emanated from the bodies. These children, who were both very intelligent, complained of no other uneasiness than a constant gnawing or craving at the pit of the stomach, which was never altogether allayed, but which, shortly after a meal, impelled them irresistibly to devour everything that came in their way, however disgusting.'

The real nature of the morbid condition of the stomach and of the system in this disease is very imperfectly known. In several cases the health in other respects has appeared good, but in most cases there has been evident disease in various organs, and death has usually taken place at an early age. On the examination of the body after death the stomach has commonly been found enormously distended and sometimes misplaced; the duodenum and the rest of the intestines are usually in the same state of distension; the coats of all these organs are commonly thickened, and the valvulae conniventes (the folds of the inner or mucous membrane of the intestines) as large as in carnivorous animals. Various organic changes have at the same time been found in the mesentery and its glands, as well as in the liver, the pancreas, and the spleen.

There can be no question that most cases of this disease might be greatly mitigated, if not wholly removed, by the firm and constant restriction of the food to that quantity only which the wants of the system really require. Unless the individual have strength of mind to submit to the necessary privation, or unless, in the case of children, a steady and undeviating restraint be imposed, every attempt to remedy the evil will be vain. If a rigid regulation of the diet be enforced, the cure will be materially assisted by a course of nauseating purgatives, as oil of turpentine rendered more active by castor oil. Several cases of great intensity have been completely cured by a steady treatment conducted on these principles.

When inordinate appetite is merely the result of some other unusual or morbid condition of the system, that is, when it is what is called symptomatic; when, as is often the case, it is the consequence of great fatigue, or of inanition, from long-continued acute disease, or of some malady attended with an extraordinary degree of secretion and excretion, and therefore with the removal from the system of a proportionate quantity of its nutrient matter, the disease can be cured only by the restoration of the system to its ordinary and sound state.

BULL-FIGHTS, a very ancient and barbarous amusement, which, under different modifications, has descended to modern times, and is found in many of the countries of Europe, though the English form of it (bull-baiting) may almost be said to have gone out of fashion.

Bull-fights were known to the ancient Egyptians; and also to the Greeks more than 300 years before Christ. The Thessalians had their regular festivals or days of bull-fighting. As the Thessalians were celebrated for their skill in horsemanship, it is probable their combats resembled those of the Spaniards, the most celebrated of modern bull-fighters, and the only European people that have preserved the sport in its perfection. It appears to have been introduced by the Moors, who are generally said to have introduced it with the djerid and other equestrian and warlike sports into Spain in the 8th century. Orig-

nally it gave occasion to a display of clever horsemanship, dexterity with the lance, and personal courage, when high-born cavaliers were the combatants; but when, on the accession of the Bourbons to the throne of Spain, it ceased to be patronised by the court, it became unfashionable, and was only maintained by the popular interest in its favour; and being so left, it soon became vulgarised, and the professional actors, like the boxers of our prize-ring, are now of a low class, though occasionally patronised by those of a higher class, particularly since the sport has again been sanctioned by the presence of the sovereigns. Though disgusting from the quantity of blood of bulls, horses, and men that frequently flows in the arena, a true Spanish bull-fight like those exhibited at Madrid, Seville, Cadiz, and the great cities of the south, is a gallant and imposing spectacle. It has often been described in prose and verse. In the first canto of Lord Byron's *Childe Harold*, there is a description of one at Cadiz, which is not more poetical than it is correct. A few words in plain prose may convey some notion of the game, to which Spaniards of both sexes and of all ranks are passionately attached.

The amphitheatre, or plaza de toros, in the great cities, is an extensive edifice, partly built of stone and partly of wood; it is open at top, with seats running round it and rising above each other, and is capable of accommodating from 5000 to 10,000 spectators. The lower tier of seats is protected by a parapet, in front of which a very strong wooden fence, about six feet high, is erected; this fence runs (like the seats) all round the arena, at the distance of from twelve to twenty feet from the lowest tier of seats. The ground-plan of the plaza thus describes two circles; No. 1, or the inner circle, being the battle-ground, and No. 2, or the outer circle, being the place where the men on foot take

shelter when hard pressed by the bull. To allow of the latter movement, openings just large enough to admit a man sideways are made in the strong fence which separates the two circles.

The actors on the arena are, first, the bull, which ought to be of the fierce Andalusian breed; second, the picadores, or men who attack the bull on horseback; third, the banderilleros, who attend on the picadores, and are armed with sharp goads furnished with coloured streamers; fourth, the chulos, or men with glaring coloured cloaks, with which they distract the bull's attention; and fifth, the matador, who directs most of the movements, gives the bull his finishing-stroke, and who, in reality, may be considered as the chief performer. Each matador, as well as each picador, has generally two chulos attached to his person. When all is ready, there is a flourish of trumpets; then the picadores, with lances in rest, caracole within the barricade, and the banderilleros and chulos, in their old Spanish and bespangled dresses, step lightly into the arena. The trumpets sound again—the combatants take up their places, and all is quiet in the amphitheatre. Another flourish, and the bolts of the bull-stall are withdrawn, the gate in the barrier is thrown open, and the spectators shout *El toro!* (the bull!) who, if he be a good one, gets into the midst of the arena at a single bound. The picadores await his furious onset, their object being to wound him with the lance, and then give him the go-by, avoiding the shock of his charge, which is sometimes fatal both to man and horse. Generally speaking, however, the horses used for the sport are of the most miserable description; and the skill of the rider is only shown in exposing the horse to the attack of the bull, while he avoids it himself. The horse is frequently gored, yet succeeds in bearing his rider away in safety, then drops, and is hauled out of the arena, "No vale na" (he is worth nothing) being the reply to any expressions of pity for his fate. When any picador is closely pressed, the footmen, both banderilleros and chulos, rush to his assistance, and, by pricking him with their darts, and waving their red, scarlet, and yellow scarfs before his eyes, nearly always succeed in drawing off the bull's attention. These attacks and defences are repeated until successive wounds from the lance and the shorter goads of the banderilleros cause the poor bull's flanks and shoulders to stream with blood. At first these wounds madden him, but the loss of blood and his furious exertions gradually weaken and dispirit him. In most approved bull-fights, at a certain stage, the picadores or horsemen withdraw, and leave the combat to the banderilleros, each of whom carries a banderilla or dart, about two feet long, ornamented with a pennant, in each of his hands, but no cloak, or dazzling scarf of any kind on his arm. Thus armed, the banderillero runs up to the bull, and stopping short when he sees the animal's head lowered to attack him, he fixes the two shafts, without flinging them, behind the horns of the bull, at the very moment that it is preparing to toss him. The pain thus occasioned makes the bull throw back his head and lose his blow, on which the nimble-footed banderillero retreats, one of his comrades comes up to the charge, or a chulo throws a cloak over the bull's horns, and so, by blinding it, prevents the renewal of the combat for some seconds. Should the banderillero fail in fixing his darts, and should the bull be still fresh, he must rush to one of the openings left in the wooden fence, and creep

into the outer circle. The nimblest of the banderilleros, instead of seeking the opening, which may be too distant for them to make in face of the bull's horns, will lay their hands on the top of the fence and spring over it; and a fine bull of the true breed has sometimes been known to go over after them, clearing the six-foot fence as an English hunter takes a five-bar gate.

At length, bellowings of rage and pain, and his wavering, uncertain onsets, show that the poor bull's death is near. Then a great man in the privileged government boxes waves his handkerchief, and another flourish of trumpets gives the signal to the matador to come forward and do his last office. Followed by some chulos as auxiliaries and assistants, the matador advances with a red mantle, or a piece of red cloth attached to a short handle, in his left hand, and a long, well-proved sword in his right. He first of all drops on one knee in front of the royal or government box, doffs his cap, asks permission to finish the affair, draws his arm across his breast to the right and left, throws down his cap as a pledge which he must redeem, and then rises to do his work. The perfection of his performance consists in this—he must wait the bull's charge, his person being partially, and his toledo blade wholly, concealed behind the extended cloak, and he must so receive the bull on its point that the sword shall penetrate up to the hilt in that particular part of the animal where neck and shoulders meet. When this happens, the bull staggers for a second or two, and then drops in the midst of the enthusiastic shouts of men, women, and children. As soon as the bull is dead, and sometimes before, another blast of trumpets is heard, and four powerful and richly-caparisoned mules, with large bells round their necks, and harnessed abreast, trot into the arena. Their traces are hooked to a cross-bar, which is attached to the bull's horns; trumpets are sounded and hands clapped, and away gallop the mules, bull and all. The barriers are again closed, and the lists ready for another exhibition of torture and blood. (See Ford's *Handbook of Spain*, vol. i.; *Tauromaquia*, a series of thirty engravings, representing all the implements, costumes, and different operations, published at Madrid in 1804.)

BULLETIN, a French word which has been adopted by the English to signify a short authentic account of some passing event, intended for the information of the public. Bulletin is derived from *bulletin* a sealed despatch. (Ducange, 'Glossarium.') When kings and other persons of high rank are dangerously ill, daily bulletins are issued by the physicians, relative to the state of the patient. In times of war, and after a great battle, bulletins are sometimes issued from the headquarters of the victorious army, and are sent off to the capital to inform the people of the success.

BULLETS. The general mode of making bullets is noticed under SHOT-MANUFACTURE; but a few special methods may be adverted to here. A patent for making bullets was taken out in America in 1849, in which the bullet is formed by punching. The end of the punch has a hemispherical cavity, and a die is used which has a similar cavity. A strip of sheet lead is laid on the die, and the punch is brought down upon it with a force sufficient to sever a small piece of lead, and to form it into a globular shape by means of the two hemispherical cavities.

Several years before, however, in 1840, Mr. David Napier had patented a method, somewhat similar in principle, but more comprehensive, for making bullets in which great accuracy of form may be required. The machinery consists of two sliding plungers, placed horizontally and opposite to each other, each carrying a hemispherical die. The meeting and closing of the two dies give a perfectly spherical form to any substance compressed between them. In the centres of these plungers are two sliding plugs, which, in the retrocession of the plungers, are urged forward by a spring placed behind them, and drive out the compressed ball. An alternating motion backwards and forwards is given to the plungers. Strips of lead having projections, prepared either by rolling or casting, are supplied to the machine, the continuous pressing of which converts the projecting pieces of lead into perfect spheres, held together by a thin film of lead. The strips are then taken to a small hemispherical punch, working vertically into a circular bed the same size as the balls; and on bringing down this punch by means of a foot treadle, the balls are cut out, fall through the bed, and roll down a trough into a proper receptacle. This method of making bullets by compression was at one time adopted by the government at Woolwich Laboratory, the apparatus being worked by steam.

A proposal has been made to construct bullets of lead wire, by coiling the wire upon rests, so arranged as to allow the wire to be fed downwards into a machine, where it can be measured or gauged, cut off to the proper lengths, and compressed by forcing through a die or dies.

The Ordnance estimates for 1857-8 contained an entry of 1000*l.* paid to Mr. Greener, the gunmaker of Birmingham, for his invention of a peculiar expanding bullet to be used with rifles.

The more curious and complicated forms of bullet, such as that just adverted to, will be best described in connection with the remarkable weapon to which they chiefly belong. [RIFLE.]

BULLION, a term used in political economy, and particularly in relation to questions of currency and banking, to denote the precious metals gold and silver in their raw state, or, more properly, as they came from the refiners, and before they are coined or otherwise manu-

factured. This is the proper sense of the word, but it is very commonly applied, in speaking of exportation, to include either coined gold or coined silver. For details of the early use, as a medium of exchange, and of the modern application of gold and silver to the purposes of currency, the reader is referred to Jacobs' 'Historical Enquiry into the Use and Consumption of the Precious Metals;' Baron Humboldt's 'Essai sur la Nouvelle Espagne' may be consulted for accounts of the modes of extracting silver from the mines of South America, whence the principal supply is derived to Europe, with estimates of the quantities exported thence since the beginning of the 15th century, &c.

Full accounts of the late discoveries of gold in California and in Australia, New South Wales, and Victoria, will be found under those heads in the GEOGRAPHICAL DIVISION of this work. Very considerable supplies of gold have been obtained, of late years, by the Russian government from the mines of the Ural Mountains.

All nations, with very few exceptions, as they emerge from a rude state of society and manners, have been found to adopt bullion as a means, more or less exclusively applied, for exchanging products and supplying man's wants; and bullion has peculiar fitness for serving the purposes of a medium of exchange or money; for these reasons:

1. Bullion, whether in its form of gold or of silver, has the property both of being divided into small portions and of having those portions re-united, without in either case suffering any sensible loss of intrinsic value: thus a given quantity of bullion may be easily made to represent values proportioned to the prices of a corresponding quantity of articles of purchase for which it is required.

2. Bullion is the same in quality all over the world; an ounce of pure gold dug in the Ural Mountains is exactly similar to an ounce of pure gold taken up in Australia; an ounce of pure gold extracted from the earth 100 years ago is of precisely the same quality as an ounce of pure gold got yesterday. Exposure to weather, the scorching sun, or the rigour of frost, produces no deterioration of its quality. From all which it follows, that the relative weight of any portion of it determines at once its relative quantity and value to every other portion. Two ounces of gold are worth exactly twice as much as one.

3. Bullion, in each of its kinds, when properly treated,—that is, with a proper mixture of alloy,—is hard enough to resist friction, to a very considerable extent, for a great length of time. Moreover, it is not liable to corrode or rust, and therefore is fitted for the purposes of a circulating medium, as both kinds may be so prepared as to be capable of passing from hand to hand for the purposes of trade and commerce, and of being carried about in the shape of coins for lengthened periods without sensible diminution from abrasion.

4. Bullion is not so rare an article, and therefore not so dear, as to produce the consequence, that the quantity of gold or of silver equivalent to a given quantity of commodities, is in general so small as to be inconvenient. It is not found therefore in practice necessary to coin gold or even silver into such minute pieces, in order to serve the purposes of the vast majority of transactions, as to be easily liable on that account to loss. On the other hand, bullion is nowhere so abundant, and therefore so cheap, as to make it necessary to carry about, with you, anything more than a very moderate weight of it, in order to answer the ordinary purposes of the purchase of commodities, or the effecting of payments. A solid cube of a little more than five inches of gold contains the value of 10,000*l.*

5. Bullion, in both kinds, is capable of receiving and retaining, for long periods, stamps, impressions, characters, &c., by which the weight, the degree of purity, or the value in exchange of each coin may be certified, as may be necessary according to the habits of the nation in which it is to circulate. The alloy spoken of above as being mixed with coined bullion, consists usually of copper, which is introduced for the purpose of adding hardness to the piece, the value of the baser metal thus incorporated being reckoned for nothing. By this is not meant that the alloy is in itself valueless, but, inasmuch as the operation of disuniting it from the pure bullion would cost more than the value of the base metal after it was extracted; for this reason, a piece of gold or silver bullion in a coined shape, and therefore mixed with alloy, is estimated in currency by the quantity of the precious metal only which is contained in it.

But besides its employment for the purposes of coined money, and for decoration, for personal ornament, for plate, domestic utensils, and other uses, bullion has another very important use, as an international medium of exchange; and when employed in this way it is usually, though not always, formed into bars or small blocks. If, as the result of a given period of trading transactions between two countries, as France and England, it is found [the mode of ascertaining the result will be fully explained under EXCHANGES] that France has imported from England commodities, to a greater value, than England has imported from her, there will be a number of merchants in England whose correspondents in France will owe them the price of the English goods which have been sold into France; and these debts it will not be possible to settle by means of bills of exchange, drawn on persons residing in England, and payable here, because, on the whole, there will be nothing owing from the English side to the French side. In such case therefore it becomes necessary for the French debtor to look out for some commodity that is in general request, and which there-

fore mostly finds a ready market all over the civilised world; and to send so much of that commodity into England as may, by its sale there, realise such a sum as will pay his debt there. The commodity, of all others, best conforming to this condition is bullion, for which, owing to its adaptation to many purposes and its supplying many wants, real or imaginary, there is always a steady demand in commercial emporiums. The French debtor therefore buys the requisite quantity of gold or silver in bars (sometimes called *specie* in commerce) and transmits it to England in time to pay his debt at the expiration of the credit that has been given him. Thus bullion acts as a medium of international exchange, and performs a most valuable service to society.

In England, bullion, and chiefly bullion in bars, discharges another function of vast importance, as the basis of the paper currency, so far as that currency consists of the promissory notes of the Bank of England, which are practically equivalent, for all the purposes of money, to gold and silver coins, being made by law a legal tender at all places and in payment of all debts and purchases, except at the Bank of England and its branches. [See further, BANKING; CURRENCY.] By the expression that bullion is the basis of the Bank paper currency, is meant, briefly, that there must always be a certain proportion maintained between the value represented by the Bank of England notes that are issued and outstanding in the hands of the public, and the value of the bullion which the Bank has in its possession in its vaults in Threadneedle Street, London. This is fully explained in that part of the article BANKING which treats of the Bank of England.

At the Mint, gold bullion of the standard fineness is bought at an uniform price of 3*l.* 17*s.* 10½*d.* an ounce; and the meaning of the expression is, that in return for 40 lbs. of gold the Mint gives 1869 sovereigns, or pieces of equal fineness, weighing 40 lbs. (See 'Edinburgh Review,' Oct. 1846, p. 328.) No seignorage is charged for this service.

At the Bank of England, all standard bullion offered for sale is bought; it is not discretionary with them whether they will buy or not; that is to say, as any person taking the proper quantity of gold bullion to the Mint may have it coined into a sovereign, so any person taking five times that quantity of gold bullion to the Bank may obtain a 5*l.* Bank of England note for it. Or in other words the Government are bound by law, through the issue department of the Bank of England, to do what is practically to coin into 5*l.* notes all the gold and silver that is offered for sale there. ('Evidence before Committee of House of Commons, 1858, on Bank Acts, &c.,' pp. 144, 147, 148, 153, 155, 186, 187, 191.)

In practice it is considered to be somewhat more desirable, for the importer of bullion, to take it to the Bank than to the Mint, because at the latter he must wait for the payment of the price until the bullion can be coined into sovereigns or silver money as the case may be, thereby losing interest; at the former he receives the payment immediately in Bank notes, the Bank charging only a commission of one penny per ounce. But there does not appear to be much ground for the preference of the one mode of exchanging the bullion over the other, as it is probable that the loss of interest, by the delay at the Mint, is pretty accurately measured by the charge for commission made at the Bank. However, these two modes being open to him, the law gives to the importer of bullion a perfect freedom, without the leave of anybody, to convert his commodity into one or other of the circulating mediums—either the metallic or the paper currency—of the country, as he pleases, at an extremely small cost.

The bullion thus obtained by the Bank of England, in ordinary periods of trade and commerce, is found to accumulate, and frequently it has risen to very large amounts. On the other hand, all panics or periods of pressure and stagnation and want of confidence in the commercial body of this country, have been observed to be preceded by a continuous drain of the bullion out of the coffers of the Bank, arising from bullion being in demand for exportation. The panics of 1783, 1793, 1795, 1797, 1816, 1825, 1836, 1840, 1847, 1857, were each of them preceded by such a drain. The exports of the precious metals in the course of 1825 repeatedly, it has been stated, amounted to a million sterling a month. Hence the state of the bullion in the Bank, as shown in the periodical returns of its state which the Bank is by law obliged to publish, furnishes a criterion of the state of commerce, and of the money market, of great value to bankers and merchants; enabling them, to a considerable extent, to be early aware of the approach of a season of pressure and failure of confidence, when there will be a demand for the legal tender in payment of debts, and to make their preparations accordingly. This is done by converting outstanding securities into money and Bank of England notes, by reducing the number and magnitude of their transactions, and by other measures. Bullion, therefore, in this point of view, is closely connected with questions of currency and commercial prosperity. [CURRENCY.] It has been supposed that the obligation upon the Bank of England to give their notes for all the bullion that may be offered to them, whether they want it or not, had an effect, by increasing beyond the wants of the country the circulating medium, to depress the current rate of interest, and so cause British capital to seek investment in countries, such as America, where higher interest was, and sometimes in the event fallaciously, held out; but the highest authorities on the subjects of circulation, the money market, and commerce, are confidently of opinion that no part of the cause of the low rate of interest, which sometimes prevails

in this country, is to be attributed to this source. Perhaps this question deserves further investigation; because, whatever tends materially to depress the rate of interest has been shown, by modern experience, to be a source of evil upon the whole; it not being in these times true, as perhaps it might have been according to the experience of the less speculative times in which David Hume wrote, that "Interest is the barometer of the state, and its lowness is a sign, almost infallible, of the flourishing condition of a people." ('Essay on Interest.')

Until of late years, there was no means of ascertaining the quantities of bullion imported and exported in this country; the official tables not taking notice of transactions in specie. (Hamilton, 'Progress of Society,' p. 315.) Now (1859), however, it is otherwise; and the following table, which was prepared by the authorities of the Bank of England in 1858 for the use of the Committee of the House of Commons named above, gives an interesting view of the additional supplies of the precious metals which have been poured into Europe. In 1849, the newly-discovered gold mines of California began to add perceptibly to the arrivals of gold in Europe; in 1851, the supply was increased by the still more fertile discoveries in Australia, &c. The result is this:—

ESTIMATED INCREASE OF THE EUROPEAN STOCK OF BULLION IN SEVEN YEARS.

Years.	Imports from the producing Countries.		Exports to the East from Great Britain and the Mediterranean.	
	Gold.	Silver.	Gold.	Silver.
	£	£	£	£
1851 . .	8,654,000	4,076,000	102,000	1,716,000

1857 . .	21,366,000	4,050,000	529,000	20,146,000
	£130,876,000	29,870,000	5,420,000	56,676,000

Thus the total import of gold in the seven years may be put at 130 millions sterling; the exports of gold bullion and British gold coin to India, China, Australia, the Cape of Good Hope, Brazils, West Indies, United States of North America, &c., may be taken at 22½ millions; leaving an increase in the European stock of gold bullion of 107½ millions sterling. Then the imports of silver from the producing countries in the same seven years being 29,870,000*l.*, and the exports to India and China, 56,676,000*l.*; make the quantity of silver withdrawn from the European stock to be 26,800,000*l.* Therefore, on the whole, the estimated increase on the stock of European bullion is equal to 80,700,000*l.* ('Companion to the Almanack,' 1859, p. 170; 'Report of Committee on Bank Acts,' 1858, pp. iii., iv.)

It may be worth noting, however, that from 1810 to 1833 the supply of the precious metals was considered to have decreased to an extent unknown for three centuries previously;—according to Jacob, at a rate not less than 20 per cent.; and in proportion as the European and American trade with India and China increases, the stock of silver bullion may be expected to decrease in Europe, because that trade, to a great degree, is carried on by means of silver; that is, instead of exports from the East being paid for in European or American manufactures, the returns for the most part are made in silver bullion. Therefore, until a change takes place in the habits of the people of China and India, causing a demand for the articles in general demand among more advanced and civilised populations, and in the absence of an increase in the average supplies of silver from the mines, the stock of it in Europe must necessarily diminish.

The increase in the uses to which bullion, especially gold bullion, has been applied of late years in this country is very perceptible. Gold is much more extensively and generally used for plate, in the making of watch and pencil cases, spectacles and eye-glasses, earrings, studs and buttons, &c., and much oftener met with in the shape of trinkets and articles of bijouterie, than formerly. The gold consumed in gilding at Birmingham alone is worth 50,000*l.* annually. (Whately, 'Lectures on Polit. Econ.,' p. 156.) Also, the quantity of bullion thus employed never suffers any perceptible diminution; because, in general, articles of plate, ornament, bijouterie, and trinkets are not melted down when the price of bullion in the general market is high, with the intention of replacing them when bullion falls: it is found by experience that the cost of manufacturing is such as to prevent that: over and above the consideration that a peculiar pride is felt in the possession of such articles, which causes, in most persons, a strong reluctance to part with them. Hence the quantity of bullion which is employed in the forms of decoration and ornament, and generally in application to the arts, in any of the civilised countries of the world, would supply a kind of test or measure of the wealth of the country; because it is, in ordinary times, subject to no variation except that of increase: but there are no means of ascertaining the quantities of bullion thus used.

Nor is it more practicable to ascertain the amount of bullion which is in the hands of the people, in this country, at any given time; because large proportions of the metallic, especially the gold, currency, are at times withdrawn from the circulation in order to be exported as bullion, when the state of the exchanges renders such exportation profitable. [EXCHANGES.] It may however be interesting to see the amount

of gold and silver coins issued during the year 1857, the last for which we have the account :—

Gold.	Value.
Sovereigns	£4,495,748 4 10
Half Sovereigns	364,111 17 4
Total gold	£4,859,860 2 2

Silver.	Value.
Florins	£167,112 0 0
Shillings	128,106 0 0
Sixpences	55,386 0 0
Fourpences	69 6 0
Threepences	22,034 2 0
Twopences	39 12 0
Pence	33 0 0
Total silver	£372,780 0 0

(“Companion to the Almanac,” 1859, p. 169.)

Still more difficult must it be to arrive, upon reasonable grounds, at an estimate of the value of the bullion in circulation, in the shape of coined money, throughout the world. Nevertheless, such calculations have been made by various political economists; of these, the following are perhaps the most trustworthy. The quantity of coined money in the world has been estimated thus :—

By Storch,	at 221 millions sterling.
„ Humboldt, „ 325 „ „	
„ Jacob, „ 380 „ „	

BULLS, PAPAL. Letters issued from the papal chancery, and so named from the *bullo* or leaden seal which is appended to them. The difference between bulls, briefs, and other Apostolical rescripts, is noticed under the word **BRIEF**. Bulls are written on parchment. If they regard matters of justice, the seal is affixed by a hempen cord; if of grace, by a silken thread. The seal bears, on the obverse, heads of St. Peter and St. Paul: on the reverse, the name of the pope, and the date of the year of his pontificate. In France, in Spain, and in most other kingdoms professing the Roman Catholic faith, bulls are not admitted without previous examination. In England, to procure, to publish, or to use them, is declared high treason by 13 Eliz. c. 2. The name Bull has also been applied to certain constitutions issued by the emperors. In affairs of the greatest importance bullæ of gold were employed, whence they were called Golden Bulls.

Eleven folio volumes, published at Luxemburg, between 1747 and 1758, contain the bulls issued from the pontificate of Leo the Great to that of Benedict XIV., from A.D. 461 to A.D. 1757. The two most celebrated among them are, that ‘In comâ Domini,’ which is read every year, as these words imply, on the day of the Lord’s Supper (Maundy Thursday): it denounces various excommunications against heretics and other opponents of the Romish see: and the bull ‘Unigenitus,’ as it is called from its opening words, “Unigenitus Dei, filius,” issued by Clement XI. in 1713, condemning 101 propositions in Quesnel’s work, or in other words, supporting the Jesuits against the Jansenists in their opinions concerning divine grace.

The most remarkable Imperial Bull is that approved by the Diet of the Germanic empire in 1356, in which Charles IV. enumerated all the functions, privileges, and prerogatives of the electors, and all the formalities observed in the election of an emperor, which were considered as fundamental laws till the dissolution of the Germanic body in 1806. We believe that the Latin original is still preserved at Frankfurt with the golden seal, or *bullo*, from which it derives its name, appendant to it.

BUOYANCY is the power which certain materials have of being supported at the surface of a fluid so as to sink in it as much only as a part of their depth or thickness; thus ice, some woods, &c., are said to have buoyancy in water. Almost all solid bodies have the power of floating on mercury. The term is frequently used to designate the weight by which a solid mass of wood, or a vessel of wood or metal, can be made to sink in water till its upper surface is on a level with that of the water, or till a horizontal section of the body, at a given distance from the upper or lower surface of the latter, is on that level.

It is shown [HYDROSTATICS] that, when a body is immersed in a fluid, the weight of the body with whatever it may carry is equal to the weight of as much of the fluid as is equal in volume to the immersed part of the body. Hence, if the specific gravity of a body and that of a fluid are given (the former being less than the latter), the buoyancy may be found. Thus, by the rules of mensuration, find in cubic feet the volume of the body, if it is to be wholly immersed, or the volume of the part only which is to be under water, and multiply it by the specific gravity of water (the weight of a cubic foot of the fluid), the product will be the weight of the water displaced: subtract from this product the weight of the body, and the result will be the required buoyancy, or the weight which it will carry without sinking lower than the given depth. If the body, suppose it to be a log of timber, cannot be actually weighed, the product of its volume by its specific gravity will express its weight.

If it be required to find the volume of a rectangular mass of timber,

of given depth, which will support a given weight, the following equation may be formed :—

Let s be the unknown area of a horizontal section through the mass of timber, and consequently the horizontal surface of the displaced water. Let d be the given depth of the mass of wood, and d' the given depth to which it is to be immersed. Let g be the specific gravity of the wood, and g' that of the water; also let W be the given weight which is to be supported:

$$\text{Then } s \times d \times g + W = s \times d' \times g';$$

$$\text{whence } s = \frac{W}{d'g' - dg}$$

and this value of s being multiplied by d , will give the required volume.

In a similar manner may the buoyancy of casks or other vessels be found, or the number of vessels which would be required to float any given weight; the volumes being found by the rules of mensuration, and the weight of a vessel by experiment or by the volume and specific gravity of its solid part.

This proposition is useful in determining the amount of volume which would have buoyancy sufficient to raise a sunken ship, or in determining the dimensions of a floating bridge which may support a given weight of troops or artillery.

As regards a ship, the calculation of buoyancy is by Sterling’s rules [STERLING’S RULES] reduced to a very simple formula. It will be sufficient however here to mention some interesting facts connected with the subject of buoyancy.

To the uninitiated, the circumstance of the absolute *weight* of a ship of war being known must appear a difficulty; not so however to the naval architect. The above equation shows that weight may be as readily ascertained by *measurement* as by *experiment*. Hence we find (Peake) that a man-of-war of 120 guns, with stores and equipments to load water-line, and which no human means could easily place “in the balance,” weighs 4760 tons—the mere hull weighing 2462 tons, as seen in the following tabular arrangement :—

Rate of Ship.	No. of Guns.	Weight in Tons of					
		Guns.	Anchors.	Cables.	Masts and Yards.	Hull.	Material received on Board.
1st	120	273	20	86	64	2462	2208
2nd	84	203	17	75	63	1559	1762
3rd	74	156	14½	66½	45	1600	1428
4th	50	131	14	51	46	1308	892
5th	42	72	9½	31½	27	760	832
6th	26	48½	7½	24½	22½	510	450
Sloop ship-rigged	18	16	4½	15½	10		480

Such are (or rather have hitherto been) the buoyancies or displacements of the different classes of her Majesty’s ships; but a vast change is in progress. Naval architecture must henceforth conform more absolutely to the improvements suggested by the use and development of steam-power. The question of projectiles [GUNNERY], now only dawning upon the world, as experiments increase in number and interest, must also greatly modify the form of ships, and render the consideration of “buoyancy” of still more importance to Great Britain as a nation, inasmuch as the change of material in substituting “plates” of iron for planks of oak will effect a total revolution in the “lines” and floatation of ships. [SHIP.] The subject, so congenial and important to Englishmen, will be treated in this Cyclopædia accordingly.

Since the year of the Great Exhibition in Hyde Park, the consideration of “buoyancy” has been more prominently before the public from the attention drawn towards it in the investigation of the qualities of various forms of life-boats. Such investigation resulted in the production of a boat which is now known as Peake’s life-boat, and is extensively used on the coast. [LIFE-BOAT.] But, whatever precautions may be taken for the general safety of a crew, it is notorious, that the encouragement given by the Shipwrecked Mariners’ Society to fishermen and mariners to avail themselves of the means of “individual buoyancy” is met with indifference, and hundreds of lives are consequently lost yearly. The lamentable effects of this professional prejudice are to be seen in the number of widows and orphans at all our sea-ports and fishing villages, stretching to a mere comparative film the benefits which the funds of the Shipwrecked Mariners’ Society might otherwise annually effect, and paralysing its praiseworthy endeavours to alleviate, by the weightier and more concentrated distribution of its humane and seasonable assistance, the misery which appeals so loudly to our sympathies.

(Peake’s *Ship-Building*; *Shipwrecked Mariners’ Magazine*, &c.)

BUOYS.—French, *Bouées*; German, *Ankerbojen*; Dutch, *Ankerboeien*; Danish, *Ankerbojer*; Swedish, *Ankerbojor*; Italian, *Garitelli*; Spanish, *Boyas*; Portuguese, *Boias*. Until the 36th year of Queen Elizabeth all public buoys in this kingdom were under the management of the Lord High Admiral, but in that year (1594) the queen, by a warrant dated 11th of June, granted to the corporation of the Trinity-house of Deptford—

strand the right of "making, erecting, setting up, placing, or laying out, all buoys, beacons, marks, and signs for the sea or sea-shore, to hold the same with all profits and emoluments thereunto belonging, as of the manor of East Greenwich, in free and common socage." On laying down any public buoy, the officers of the Trinity-house corporation give notice to the public of its form, colour, and exact situation, and of the reason for its being laid down; and notifications are also made upon their removal, whether the same arises from design or through accident. By the acts 6 Geo. IV. c. 125, and 17 & 18 Vict. c. 104, it is provided, "that every person who shall ride by, make fast to, or remove, or wilfully run down or run foul of any vessel placed to exhibit lights, or any buoy or beacon belonging to, or placed by, any corporation or society having lawful authority to place the same, shall, besides being liable to the expense of replacing or making good any damage occasioned thereby, forfeit for every such offence any sum not exceeding 50*l.* nor less than 10*l.*" The amount of revenue annually collected for the use of buoys by the Trinity-house corporation is according to the tonnage of the vessels frequenting the ports in or leading to which buoys are placed; the rates vary according to circumstances.

Protection is given to private buoys by the 1st and 2nd Geo. IV. c. 75, in which it is enacted, that "if any person shall wilfully cut away, cast adrift, remove, alter, deface, sink, or destroy, or in any way injure or conceal any buoy, buoy-rope, or mark, belonging to any ship or vessel, or which may be attached to any anchor or cable belonging to any ship or vessel, whether in distress or otherwise, such person so offending shall, upon conviction, be adjudged guilty of felony, and shall be liable to be transported for any term not exceeding seven years, or to be imprisoned for any number of years, at the discretion of the court."

Buoys are either hollow, floating, water-tight bodies, formed of various substances, or they are masses of wood, reeds, &c., which are specifically lighter than water. A well-regulated system of buoys is of the utmost consideration; for on coasts where accumulations of sand and silt are continually forming and changing their positions, dangers are detected only by the vigilance of authorities, whose special duties are to watch over the navigation of shipping in the channels and entrances to our ports.

Buoys are anchored or "moored" in the neighbourhood of dangers, and usually have the name of the sand, or shoal, or spit of rocks painted on them. They are coloured red, white, black, or often chequered in these colours. Their chief use may be familiarly illustrated thus: Suppose a channel or coast to abound so much in reefs or sands that a safe passage among them could only be made by sailing in various directions (and many parts of our shores, such as the Thames, the Mersey, Spithead, &c., are beset with these difficulties); safe passages among these are so "buoyed off," that buoys of certain colours line, for example, the right-hand side of the passages, while buoys of a different colour mark the left-hand side of the passage or channel. Buoys are also attached to ships' anchors, and mark their position when these are let go. A large saving of property is thus effected, as the buoy facilitates the recovery of the anchor in cases where the cable has been broken, or when it has been cut in order to provide, on emergency, for the safety of the ship, and when time or other circumstances did not permit of the anchor being *weighed*, or lifted into the ship. Those used for shoals are generally called "Can Buoys" (*fig. 1*), and frequently have balls or beacons attached; those for ships' anchors are termed "Nun Buoys" (*fig. 2 and 3*), and are of wood or iron. Another

Fig. 1.

Fig. 2.

Fig. 3.

kind is used for mooring ships in harbours or sheltered roadsteads; these are generally cylindrical (*fig. 4 and 5*) and have a large iron ring

Fig. 4.

Fig. 5.

attached to the part above water. Buoys are also used to mark the position of a submerged wreck, and are usually painted green, and have the word "Wreck" in white letters. In 1853, special attention was given to the construction of buoys. The form of a floating body which should offer the least resistance to rushing water, (such floating body being confined to the ground by a chain and anchor,) and be capable of mounting the very crest of a wave, and thus be uniformly visible to

mariners, was a desideratum which only nature itself could satisfy. Like the naval architect, who in his extremity availed himself of the lines of the fish as a criterion of form for "speed," so did the mechanic and engineer look to nature for hints on true principles in mooring; and an excellent method of confining a floating body to the ground beneath was observed in several water-plants, and particularly in the lotus, and the gorgeous Victoria Regia. It was for Mr. George Herbert to perceive from these that the cable or confining apparatus should not, as before, be attached to the lowest point of the substance immersed, but should as nearly as practicable be made to hinge on to a point in the line of floatation. Mr. Herbert appears to have succeeded in the forming of iron buoys, of admirable qualifications, as proved to the satisfaction of the Trinity Board.

His mode of construction (*fig. 6*) gives the following advantages

Fig. 6.

namely: the tendency to pitch and roll is greatly reduced, the weight of the mooring chain is suspended from near the centre of gravity of the mass, and this, together with the resistance of the body of water filling the conical hollow of the bottom of the buoy, imparts great stability to the whole, as all leverage acting upon the centre of gravity is avoided. Thus, the body will be always borne upon the top of a wave, rather than *dragged through* it; its shape offering little resistance to the waters, and therefore the tide has very little power to force it from its floating perpendicular. They have been adopted by the Trinity-house accordingly.

From the mere buoy, Mr. Herbert was led to the consideration of floating light-vessels (LIGHT, FLOATING), and safety buoys (LIFE BUOYS). The following is a sketch of his proposed "Fairway" Lighthouse for the British Channel; but this interesting subject will be more conveniently explained under the word COLLISIONS AT SEA.

On board ship, the order to "stream the buoy and cockbill the anchor," is given when the anchor is required to be placed in such position (that is, suspended by its ring only to the cathead) as to be easily *let go* at a moment's notice; the *streaming* of the buoy meaning the throwing it into the water all clear of the ship, attached by its buoy rope to the crown of the anchor over which it is said to *watch*.

(See *Nautical Magazine*; Herbert, *On the Construction of Floating Bodies*, &c.)

BURETTE, an instrument in chemistry, invented by M. Gay-Lussac, for the purpose of dividing a given portion of any liquid into

100 or 1000 equal parts. It is accompanied by a cylindrical glass measure, containing, when filled to the line A, $\frac{1}{2}$ litre; and if the fluid to be divided be less than this quantity, the deficiency must be supplied by water. In filling this measure, it is the surface of the fluid which must be made to coincide with this mark, and not the outer margin elevated by capillary attraction above the general level. The burette consists of a large tube graduated into 100 equal parts (in the figure only half the number of the small divisions are represented), and numbered from the top downward; and of a small tube connected with the former at the base, and recurved at the top. Through this tube, if the beak be slightly greased, the contents of the large tube

may be poured with great precision, either by single drops or in a full stream. The largest divisions are 1-100 of the large measure, and the smallest 1-1000, and these may be sub-divided by counting the number of drops of the fluid under examination, which are poured out in reducing the surface of the liquid from any division to the next inferior one. The superiority of the burette over other measures consists in the decimal arrangement of the graduations, and the great rapidity and precision with which any required portion of a liquid may be added or abstracted, while one hand only is employed, the other being left at liberty to use the stirring rod or test paper.

The burette, though applicable to the processes of the analytic chemist, is a very useful instrument in manufactories where the value of numerous samples of acids, alkalis, bleaching powder, &c. has to be quickly and correctly ascertained. Several modifications of this instrument are in extensive use in this country. [ALKALIMETRY.]

BURGAGE HOLDING is one of the forms of feudal tenure in Scotland. The holders of the the fiefs under the charters of privileges in favour of the burghs, held directly of the crown, returning service by watching and warding. The return is now merely nominal, but the holding is still of the crown, the investiture or sasine being given by the magistrates of the burgh. The peculiar character of this holding has preserved in modern practice the important distinction, that while other descriptions of landed property may be subfeued ad infinitum, a burgage holding can only be transferred from one crown vassal to another, who comes in his place. All the lands held by or of a royal burgh are not necessarily held by burgage tenure. The community may, like an individual, obtain feu rights and grant subinfeudations; the proper burgage holding is applicable only to those lands to which the charter applies.

BURGAGE TENURE (England) denotes the particular feudal service or tenure of houses or tenements in ancient cities or boroughs. It is considered to be a species of socage. The incidents of this tenure, which prevailed in Normandy as well as in England, vary according to the particular customs of each borough, in consequence of the maxim that, in improper feuds (to which class this tenure belongs), the *lex et consuetudo loci* are always to be observed. (Wright's 'Tenures,' p. 205.)

Burgage tenure is supposed by Littleton and other writers to have been the origin of the rights of voting for members of parliament in cities and boroughs; and the great variety of those rights is in some measure accounted for by supposing them to be founded upon varying local customs. It is however impossible to trace the gradual steps by which the irregular rights of voting in boroughs for members of parliament, which are continued by the Reform Act (2 Will. IV. c. 45) until the extinction of existing interests, were derived from burgage tenure.

BURGESS. [MUNICIPAL CORPORATIONS.]

BURGLARY. The derivation of this word is quite uncertain. By some writers it is supposed to have been introduced by the Saxons, and to be compounded of *burg*, a castle or house, and *larron* or *latro*, a thief. But Spelman conceives that the term was introduced into the criminal law of England from Normandy, and says that he finds no traces of it among the Saxons. (Spelman's 'Glossary,' tit. 'Burglaria' and 'Hamesecken.') The offence of burglary at common law is defined

to be "a breaking and entering the dwelling-house of another in the night, with intent to commit some felony within the same, whether such felonious intent be executed or not." By the statute 7 & 8 Geo. IV. c. 29, s. 11, entering the dwelling-house of another with intent to commit a felony, or being in such dwelling-house and committing a felony, or in either case breaking out of the house in the night-time, was declared to constitute a burglary, and to be punishable with death. Simple burglary is now, however, punishable by penal servitude for life, or for a term of years, or by imprisonment not exceeding three years. The capital punishment is retained where the offence is accompanied by an assault with intent to murder, or by stabbing, cutting, wounding, beating, or striking, any person in the house. (7 Will. IV. and 1 Vict. c. 86; 20 & 21 Vict. c. 3.) The leading characteristics of this offence are, 1st, that it must be committed in the night time, that is, at a time when people are presumed to be sleeping; and therefore it is said in the books, that if there be a sufficient dawning of "day-light or *crepusculum*, either begun or left, enough to see a man's face withal," when the offence is committed, it will not be burglary. The reason of the rule is that the offence, to be complete, must have been committed in the dead of night, and it follows from this reason that a burglary might be committed in the brightest moonlight. By the 7 Will. IV. and 1 Vict. c. 86, s. 4, however, night is to be considered as commencing at nine o'clock in the evening, and ending at six in the morning.

2. There must be a breaking and entering of the house; which parts of the offence however are completed by the robber even breaking a pane of glass and putting in his hand with a felonious intention.

3. The house broken must be the dwelling-house, or, as it is called, the "mansion-house" of the person injured. By this is meant that it must be a permanent dwelling, and not a booth or tent; and also that it must be the place of the actual and personal residence of man, and not a mere stable, barn, or outhouse: unless such buildings are connected with the dwelling-house. The 7 & 8 Geo. IV., c. 29, s. 13, defines what buildings within the curtilage shall be deemed part of a dwelling-house for purposes of burglary. Upon this part of the subject a great variety of nice distinctions have arisen, for which we refer to HOUSE-BREAKING.

By the 14 & 15 Vict. c. 19, being found by night armed with intent to break into any house and commit felony, or having the possession by night of housebreaking implements, or having the face blackened or otherwise disfigured, or being found by night in a house with intent to commit a felony therein, is a misdemeanour punishable by imprisonment not exceeding three years.

BURGOMASTER, BÜRGERMEISTER, is the title of the chief magistrate of a municipal town, answering to the English mayor. In the German free towns the *bürgermeister* is the president of the executive council of the republic. This is also the case at Zürich, Basel, Schaffhausen, and some other Swiss cantons; while at Bern, Freyburg, and Luzern, the corresponding magistrate is called *schultheiss* (in French 'avoyer'), and in the rest of the cantons *landamman*; which last is a Swiss term.

BURGOS LUSTRE. A kind of gilding upon china, produced by the double sulphide of gold and potassium. The latter is prepared by heating to redness finely divided gold, with sulphur and carbonate of potash.

BURIAL. [INTERMENT.]

BURIN. [ENGRAVING.]

BURLESQUE, a word derived from the Italian adjective "*burlesco*," which is applied to qualify words, gestures, or expressions of the countenance intended to excite laughter. The Italian verb "*burlare*" means to mock or mimic, and also to laugh at a person and make him a dupe. In the latinity of the middle ages we find "*burlare*" used as synonymous with "*ludere*." (Ducange.) The burlesque style is applicable both to conversation and pantomime, and to written composition and the art of drawing. Facetious anecdotes and repartees exposing some blunder or turning something into ridicule are styled burlesque. The burlesque style however is most common in poetry, and may be defined to be a sort of good-humoured satire. There is a class of burlesque poems in every language, such as '*Hudibras*' and '*Beppo*,' in English; but of all modern languages the Italian abounds most in this species of composition, which is called "*poesia burlesca*," or "*poesia giocosa*," and also "*poesia bernesca*." [BERNI, in BIOG. DIV.] This species of poetry is divided into several branches, each cultivated by numerous writers both in the Italian and in the dialects of Italy. (Aldeano, '*Della Poesia Giocosa*.) The burlesque in the art of drawing is shown in the English caricatures, and in the sketches of low life and merry-making exhibited by many of the Dutch and Flemish painters, and also in the representations of deformed and uncouth figures, such as are found among ancient and modern sculptures. Monstrosities, however, which excite a sense of horror or disgust, cannot be properly called burlesque productions, the essential quality of the latter being to excite laughter. For the same reason, satires of the invective kind reprobating gross vice, such as Juvenal's, are quite distinct from burlesque compositions.

BURLETTA (from *Burlare*, Ital., to joke, to banter, to play), a comic *operetta*, or short opera: a musical farce.

BURMESE WARE. There are certain peculiarities about Burmese ware which render it worthy of a brief notice. The cups of small size

are made of thin strips of bamboo, woven like fine basket-work. After the first coat of varnish, the interstices are filled up with a paste made of wood-oil mixed with different fine powders, such as calcined bone, or sawdust from teak-wood. After the paste has been smoothed by the hand, the cup is laid aside to harden in a cool place; when sufficiently hardened, the surface is smoothed with pumice-stone and water. The cups are afterwards varnished three or four times, and polished by rubbing. The varnish mostly used in India and Burmah, under the name of wood-oil, is obtained by incision from the *Dipterocarpus terminatus*, and a few other trees. In the Burmese ware this varnish is not laid on with a brush, but by the hand, in order to preserve a fine surface, and to enable the workman to discover and remove any particles of dirt. When first laid on, the varnish appears of a light brown colour, which is changed to a fine black by rubbing with the hand. The varnished and polished cups are kept in a cold vault for three days, to harden the varnish. Sometimes the cups are ornamented with raised figures; these are made of the same paste that is used to fill up the interstices of the basket-work. The paste is pressed into tin moulds, and afterwards transferred to the cups or bowls; when dry, it becomes as hard and solid as wood. Occasionally the cups are ornamented with engraved designs, which are afterwards filled up with different-coloured powders, mixed with wood-oil; the surface is then smoothed with wet bran, held in the hollow of the hand. The operation is repeated, to ensure the complete filling up of all the lines; and the cups are finally varnished and polished as usual.

BURNERS. [ARGAND; GAS LIGHTING; LIGHTS, ARTIFICIAL.]

BURNING. [ARSON; BRAND.]

BURNING GLASSES AND MIRRORS. Any lens of the convex kind, or mirror of the concave kind, which collects a quantity of light within a very small space, will, if the light be very strong, such as that of the sun, also collect a considerable quantity of heat, which will set fire to many substances; or, if the glass have an aperture of some size, almost any substance whatsoever. This property has been long known. The last proposition of the treatise on catoptrics attributed to Euclid is, "By concave mirrors placed opposite to the sun, fire may be kindled;" and the reason is explained, namely, the condensation of the sun's rays. In the 'Clouds' of Aristophanes (766, &c.), Strepsiades tells Socrates that he has found out an excellent way of cancelling his debts, namely, by standing at a distance from the lawyer who is drawing up the case against him, and destroying the writing by catching the sun's rays in such a burning-glass or transparent stone as people kindle fire with. We may see under ARCHIMEDES [BIOG. DIV.] that the stories relative to his burning the Roman fleet by mirrors are of comparatively modern authority. From the end of the 17th century various experiments have been made with glasses of considerable power; but as no important results followed, beyond the establishment of the great effect which may thus be produced, the subject has become of little importance, especially, as when high temperatures are required, the oxy-hydrogen blowpipe, or the voltaic battery is at the command of the chemist. We shall, however (referring the reader to LENS and MIRROR for all stricter notions upon the subject), state some facts connected with burning glasses in a more popular shape.

It is found that heat alone without light passes very slowly through glass; that even with ordinary light very little heat is transmitted through glass; and that it is only with the full glare of sun-light that any sensible effect can be produced. If a convex lens be held directly opposite to the sun, and allowed to throw an image on a sheet of paper held behind and parallel to it, and if the sheet of paper be moved until the image of the sun thrown upon it appear smallest, the quantity of light transmitted through the glass, which remains the same throughout, is then thrown upon the smallest quantity of surface, and presents the greatest condensation of light and heat which the glass will afford. The same phenomenon would be perceived in a concave mirror, with this defect, that the surface which is held before it must intercept a part of the light.

Two glasses were made by Tschirnhausen, before 1699, which are among the earliest of the attempts to produce considerable effects; the first of 33 inches diameter and 7 feet focal length, the second of the same diameter and 12 feet focal length (old Parisian measure). A second lens received the rays and diminished the focal distance. The effect was to burn small portions of wood, or boil water, also in small quantities, in one moment; to melt small pieces of metal, to vitrify slate, &c.; to melt pitch and resins under water. But the most complete effect was produced from a lens made by M. de Trudaine, about 1774, which did not consist of glass alone, but was a hollow lens of glass, filled first with spirits of wine, which was afterwards changed for terebinthine oil. It held 140 pints (Parisian), and filled with the latter substance had about eleven feet of focal length. According to M. Brisson (afterwards cited), who made the experiments, a bar of steel, four inches long and a third of an inch square (Parisian), was completely melted in five minutes. A silver coin of three livres was melted in a few seconds, and one of six livres in nearly the same time; grains of platinum were sufficiently melted to cohere, though not to form a spherical drop.

M. Buffon, remembering the story about Archimedes, endeavoured to form mirrors which should burn at a great distance. The disadvantage of trying to gain power by increasing the aperture lies in the

great relative increase which is thereby given to the small image of the sun. No spherical glass or mirror refracts or reflects rays accurately to a point. The plan of M. Buffon was to make his mirror consist of a large number of small plane mirrors, 400 in number, so placed that they should all reflect their several images of the sun on the same point. He thus burnt wood at 200 (French) feet distance, melted tin at 150 feet, and lead at 140 feet.

The only practical application of the burning glass (if it deserves so dignified a name) of which we ever heard, is the following: A burning glass is placed in such a way that the sun shall throw its image into the touch-hole of a small cannon, at its greatest height, which thus explodes within a minute or two of noon, if there should happen to be no cloud in the way.

BURNS AND SCALDS. Burns are produced by heated solids; scalds by heated fluids. The severity of the injury is dependent mainly on the intensity of the heat of the burning body. Fluids are not capable of acquiring so high a degree of temperature as some solids; hence the immediate effect of scalds is generally less violent than that of burns. But, on the other hand, fluids flow about with great facility, and the accident often causes a very large surface of the fluid to be thrown upon the body, so that a scald which produces only a moderate degree of inflammation sometimes becomes exceedingly severe on account of its extent. As heated fluids part with their caloric in being diffused, a scald is almost always attended with a different degree of injury in different parts of its course. The extent of the surface involved, the depth of the injury, and the sensibility of the part affected, must all be taken into account in estimating the danger of the accident in any given case. A burn which produces the instantaneous death of the part it touches may be free from all danger if the injured part be circumscribed within a small compass. The worst burns which occur arise from the explosion of gunpowder, or of inflammable gases, or from the female dress catching fire; and the worst scalds from the boiling over of heated fluids in breweries, manufactories, laboratories, &c.

The immediate seat of the injury produced by burns and scalds is the skin, which is a highly organised membrane, performing a very important organic function, and endowed with a high degree of sensibility. [SKIN, NAT. HIST. DIV.] The organic function performed by it is the secretion of a quantity of aqueous fluid from the blood, which is carried out of the system under the form of perspiration. The secretory arteries of the skin are excited to such an unusual degree of action by the stimulus of the heated body, that they pour out an aqueous fluid in such quantity as to lift the cuticle from the cutis or true skin, and form a vesicle or bladder full of fluid. Such is the violence done to the true skin, that the function of all the injured portion of it is suspended; additional labour must therefore be imposed on some other organ, which must be its substitute and perform its work, otherwise a fatal disturbance will take place in the system. The lung exhales the same aqueous fluid as the skin. [LUNGS, NAT. HIST. DIV.] In proportion as the cutaneous perspiration is diminished, the pulmonary transpiration is increased; but when a large extent of the skin is destroyed, the lung is inadequate to the task imposed upon it; it cannot perform its own work and that of the skin also, and in this case great difficulty of breathing invariably comes on, and the danger is exceedingly increased by this oppression of the lung.

But there is spread over the external surface of the true skin an immense number of sentient nerves, rendering it an organ of sense. A burning body applied in such direct contact with the sensitive extremities of these nerves occasions violent pain; and this, in consequence of the sympathy which is established between all parts of the body, produces a great disturbance of the system. The abolition of the organic function, and the disturbance occasioned to the sentient part of the nervous system, both combined, often prove fatal.

Since the severity of the injury must always be mainly in proportion to the length of time the burning body continues in contact with the skin, it is important that every one should impress upon his mind the course which it is best to take in case of accidents from burns.

The upright posture is obviously not only favourable to the spreading of the flames, but to their reaching the more important parts of the body, the neck and head. Any motion of the body to and fro gives great advantage to the flames, by bringing fresh currents of air into contact with the burning materials, and it is therefore utterly absurd to run screaming about. Fall upon the floor; keep rolling over and over upon the carpet: if possible seize the hearth-rug, or the table-cover, and, enveloping the body in it, keep rolling about upon the carpet until assistance comes. The duty of the assistant is to seize the hearth-rug, or the table-cover, or a shawl, or to strip himself of his coat, or to seize any woollen or flannel clothing at hand and to envelope in it as closely and completely as possible the person on fire.

The thing to be done with the burnt or scalded parts is instantly to immerse them in cold water, ice-cold if it can be got. Should the position of the parts not allow of their immersion in water, cloths should be applied to them dipped in water, and kept constantly wet. As a means of applying and retaining cold, scraped potatoes or turnips are useful. Some persons recommend, instead of those cooling applications, stimulating substances, such as the strongest brandy, spirits of wine, oil of turpentine, or vinegar, kept on the affected parts, by means of old linen or lint soaked in the fluid. The use of these applications,

whether the cooling or the stimulating, should be persisted in until the pain ceases; the parts should then be dressed, as some recommend, with the yellow basilicon ointment, softened with the oil of turpentine; or, as others prefer, with emollient poultices often renewed. It is singular that, common as this piece of surgery is, practitioners are not agreed which of these two plans, the cooling or the stimulating, is the most efficient; and comparative trials have not yet been made on a scale of sufficient extent to determine the question. It is probable that the one may be more advantageous than the other under different circumstances, which the unprofessional person cannot be expected to discriminate. All that is necessary to be stated here is the most judicious thing to be done, in the very first instance, until professional assistance can be procured; and with this view, perhaps, the only thing that should determine the choice between either of the cooling or stimulating articles just mentioned is the facility with which they can be got. It is probable that the chief effect of all these applications is to prevent the air from coming into contact with the true skin; that is, to perform the office of the cuticle which is destroyed. Accordingly, some of the most distinguished surgeons state that they have produced the very best effects by merely covering the affected parts with old linen saturated with oil, by which the air is effectually excluded. On the same principle the part may be enveloped in cotton, or powdered over with flour.

BURNT ALUM. [ALUM.]

BURNT-EAR. *Burnt-ear*, in corn, is a disease in which the fructification of the plant is destroyed and, as it were, *burnt up*; hence its English name, and the corresponding terms of *charbon* in French and *brand* in German. *Burnt-ear* has often been confounded with *smut*, which is a similar but distinct disease. They differ in this, that in the *burnt-ear* the black powder which appears in the ear is external, and the grain has either never been formed, or its coat has been destroyed, so that the whole ear appears black or burnt. The powder also has no smell, and, being easily blown away by the wind, or shaken off in the reaping, little of it adheres to the corn or is mixed with it when ground; and except the loss of so much grain as would have been contained in the sound ears, no great detriment arises to the quality of the corn. The *smut*, or *pepper-brand*, on the contrary, is contained in the body of the grain, which retains nearly its natural form, and is carried along with it into the barn. It is only in the threshing or grinding that the diseased grain commonly called *smut-ball* is broken, when a fetid black powder is dispersed over the sound grain, which greatly deteriorates the flour, and renders the corn unfit for seed, the disease being perpetuated by this black substance. [SMUT.] *Burnt-ears* are generally observed in particular moist situations, and some lands are more subject to them than others. The disease has been often attributed to damp and warm fogs succeeding very dry weather: and hence it has been imagined that it was caused by the dews lodging in the ears and producing a species of rotteness. But microscopic observations have decidedly proved that the black powder consists of the minute germs or seeds of a parasitical fungus, which are developed in the growing ears and live on its substance.

The plants attacked by this disease may be distinguished long before the ear makes its appearance out of the sheath in which it is enveloped in its early state. There is a peculiar greenness of the leaf observable; and when the plant is examined, the young ear may already be seen attacked by the disease and beginning to put on a spotted and black appearance, which increases as it grows, and is perfected when the ear arrives at the state in which the flower should appear. In some cases the plant flowers partially or completely, and the fecundation takes place, so that the germ is developed; but it never approaches to maturity. Its outer skin is soon destroyed by the parasitical fungus, and the whole substance converted into a black powder.

De Candolle, one of the best modern authorities on the physiology of plants, has named this peculiar minute fungus the *Uredo carbo*, which he distinguishes from that which produces the *smut*, and which he calls *Uredo caries*. They are easily distinguished by the size and smell. The *Uredo carbo* (*Uredo segetum*) is composed of much smaller globules, and destitute of smell; both seem to be propagated like other cryptogamous plants by means of extremely minute germs, which are carried along with the sap into the circulation and vegetate in the ear, where alone it appears that they find the conditions necessary to their growth.

It is doubted by some whether the disease is contagious, because they have never been able to produce it by shaking the black dust of burnt-ears over the sound plants. The reason of this is probably that the exhaling vessels of the surface are not so well calculated to absorb extraneous matter, which can only enter by the spongioles of the roots. Although it is much less dangerous than the *smut*, because it is readily dispersed by the winds, yet it must more or less infect the soil, and hence the disease is more frequent where it has appeared before, and where those grains which are most subject to the disease, such as wheat, barley, and oats, have been sown in too rapid succession. As it does not adhere to the grain, steeping and washing are not so certain remedies against the infection as in the case of *smut*; but the best preservative is to drain the land well and keep it in good heart, so that the plants may be vigorous and able to resist the attacks of the parasite; for it is a well-known fact, that weak plants, as well as animals are much more exposed to the attacks of parasitical plants or

animals than those which are vigorous and robust. A judicious change of crops, or a well-established rotation, will in general secure the corn, which is sown in its proper course, from the infection of the *Uredo carbo*, provided the preparation of the land be such as to ensure a healthy vegetation.*

As this disease is extremely common, it has obtained various names in different parts of the country. In England it is best known by the names of blacks, brand, or burnt-ear; and it is often called *smut*, from the supposition that it is a variety of the same disease which attacks the external part of the fructification before the skin of the grain is formed.

BUSHEL. This word seems to be a diminution of an old English word *buss*, signifying a box or vessel, and still used for small fishing-boats. Fleta describes the bushel as containing eight pounds (librae) of corn, and eight bushels as making a quarter (quarterium); Spelman, as containing four gallons (galones) of wine. Dr. Bernard asserts the bushel to be 72 pounds troy of common corn (triticum), or 59·1667 avoirdupois. By the act of 1697 the Winchester round bushel was to be 18½ inches in internal diameter and 8 inches deep, or 2150·42 cubic inches. The standard of length implied was the old exchequer standard. By the Act of 1824 the standard gallon contains 10 pounds avoirdupois of pure water; eight such gallons make a bushel, and eight bushels a quarter. This, by the other provisions of the Act, made it contain 2218·2 cubic inches very nearly. The content of the bushel seems to have been gradually increasing. Arbuthnot (1727) makes it 2178 cubic inches; Eisenschmidt (1737) 2180·4 cubic inches. The bushel is now 36·347 French litres. The *heaped bushel*, for goods which were heaped above the measuring vessel, such as coals, fruit, &c., and which was estimated at 2815·5 cubic inches, was abolished by 4 & 5 Will. IV. cap. 49, an Act which took effect from the 1st of January, 1835. The relation which the "imperial" bushel, as it is now called, bears to other measures of capacity, and to certain weights, will be found noticed in a later article. [WEIGHTS AND MEASURES.]

BUSKIN, a covering for the foot, coming some distance up the leg, fit for a defence against dirt, thorns, &c. This word is also used in English as the translation of the Greek and Latin word *cothurnus*, which signifies a sandal with a high cork sole used by the Greek and Roman tragic actors to give an appearance of elevation to their stature, in conjunction with the mask and other stage properties. The *cothurnus* was also used by persons of high station in hunting, &c., and was often richly ornamented. The *cothurnus* was worn by ladies to add height to their stature. In Greek art, Diana is usually represented with the *cothurnus*. The colours of the buskins were varied; purple for Dionysus, white for ladies, and red for warriors. *Cothurnus* in Latin is employed in contradistinction to *soccus*, the flat-soled shoe worn by slaves and comedians. Hence, in English authors the words *buskin* and *sock* are often used for the tragic and comic drama. So Dryden,

"Great Fletcher never treads in buskins here,
Nor greater Jonson dares in socks appear."

BUST, in Sculpture, means a statue truncated below the breast. The etymology of the word is not very clear. The Romans called 'bustum' the place where they burnt the bodies of the dead, from 'bustum,' burnt. Bustum was afterwards used for the grave in which the body was buried; and lastly, in the latinity of the lower ages, for the dead body itself: 'Sanctorum busta,' the bodies of martyrs (Ducange). Bustum seems to have been used more especially for the trunk of the body without the head: "Quinque hominum busta sine capite cæsa." ('Annal. Mediolan.' in Muratori.) In the old French, 'bu' meant the trunk: "Car ils ont bien armé le chef et le bu." (Old French Romance, Ducange.) 'Busto,' in Spanish and Italian, has a similar meaning. The Italians call also 'busto' the stays which embrace and support the breast. In Sculpture, however, bust includes the head, shoulders, and breast, with the arms truncated above the elbow, and as such, it forms a large department of the art. Busts were mostly used by the ancients to represent likenesses of individuals, and were placed either upon sepulchral monuments, or in the interior of houses, or in gardens. The Greek word *Hermæ* has been sometimes considered as synonymous with the modern bust, but the *Hermæ* were merely heads placed on a quadrangular pillar. Portrait busts are of all kinds of sculpture what most employ the chisel of the modern sculptor, especially in this country; and this is consequently a branch of the art in which English sculptors excel. Chantrey especially was famous for his skill in this line; probably as much surpassing most contemporary European sculptors in the execution of portrait busts as he was inferior to several of the more eminent in the higher branches of statuary.

BUTIC ACID (C₄₀H₄₀O₄). One of the acids contained in cows' butter. It is distinguished from stearic acid by being less soluble in alcohol, and by being more easily precipitated by acetate of magnesia.

BUTTER. Butter is the fat or oleaginous part of the milk of various animals, principally of the domestic cow. The milk of the cow is composed of three distinct ingredients, the curd, the whey, and the butter;

* Steeping the seed in brine or stale urine, and drying it with fresh-slaked lime, as is usually done with wheat, is however a useful precaution, which should be adopted also with barley and oats, wherever burnt-ears have appeared in preceding crops. A solution of sulphate of copper is also generally used, and is certainly more efficacious than common salt.

the two first form the largest portion, and the last the most valuable. The comparative value of the milk of different cows, or of the same cows fed on different pastures, is estimated chiefly by the quantity of butter contained in it; and in this respect, some breeds of cows are far superior to others. The union of the component parts of milk is chiefly mechanical, as they separate by subsidence according to their specific gravities, the cream being the lightest, and the curd the heaviest; the curd, however, requires a slight chemical change for its separation from the whey, which at the same time produces a peculiar acid, called the lactic acid. From the moment that milk is drawn from the cow it begins to be affected by the air and changes of temperature, and circumstances almost imperceptible to our senses will materially affect its quality. [MILK.] Hence the importance of extreme care and attention in every step of the process of the dairy, especially in making butter.

The cows should be milked in the cool of the morning and evening; they should not be much driven or heated immediately before milking; and it is best to bring them to the place of milking some time before the operation begins. In some situations it is better to milk them in the pastures, and carry the milk home; in others, to drive the cows gently to the cow-stall. In mountainous countries the first mode is generally adopted, because the cows are apt to leap down steep places, and shake the milk in their udders more than is done by carrying it in the pail. The same practice holds good in Holland; on account of the great distance of the pastures from the home-stall, and on account also of the facility of transporting the milk in small boats, all the best pastures being surrounded by small canals communicating with the greater; so that the milk may be carried several miles without the least agitation. In England, where the pastures frequently surround the habitation of the dairyman, the cows are generally driven home twice a day to be milked. As the slightest acidity or putrescence immediately causes an internal chemical action in milk, it is of the greatest importance that the place where the cows are milked, and the persons employed, should be of the greatest purity and cleanliness. The milking-house should be paved with stone or brick, and no litter or dung be permitted to remain in it. It should be washed out twice a day, immediately before each milking; which, besides ensuring cleanliness, produces a refreshing coolness highly useful to the milk. The teats of the cows should be washed clean with water and a sponge. The vessels in which the milk is drawn from the cow should also be kept scrupulously clean.

The milk, as soon as it is brought into the dairy, is strained through a fine sieve or cloth, in order to remove any extraneous matter; and it is then poured into shallow pans, or troughs lined with lead. The best pans are of metal; either of iron carefully tinned, or of brass. Such pans are cool in summer, and in winter allow of the application of heat, which is often very useful to make the cream rise. When leaden troughs are used, they are generally fixed to the wall, and have a slight inclination towards one end, where there is a hole with a plug in it; by drawing this plug, the thin milk is allowed to run off slowly, leaving the cream behind, which runs last through the hole into the pan placed under to receive it. Glass pans and pans made of earthenware are now largely used, and have the advantage of being more easily kept clean than any others. The milk in the pans or troughs is generally four or five inches in depth, a quantity found most conducive to the separation of the cream. The place where the milk is set should have a thorough draught of air by means of opposite wire windows. The sun should be carefully excluded by high buildings or trees; and the floor, which should always be of brick or stone, should be continually kept moist in summer, that the evaporation may produce an equal cool temperature. A small stove in winter is a great advantage, provided smoke or smell be most carefully avoided, and the temperature be carefully regulated by a thermometer. All these minutiae may appear superfluous to those who have no practical knowledge of the dairy; but good butter cannot be ensured without them. It is well known that even the complexion and temperament of a dairy-woman are not a matter of indifference; and that however clean she may be, there are times when the insensible perspiration of her body will have a powerful effect on the milk. In Switzerland men are chiefly employed to milk the cows, and in all the processes of the preparation of butter and cheese. The women only clean the utensils, and carry green food to the cows when they are kept in the stable. When the milk has stood twelve hours, the finest parts of the cream have risen to the surface; and if they are then taken off by a skimming dish, and immediately churned, a very delicate butter is obtained; but in general the milk is left twenty-four hours, when the cream is collected by skimming, or the thin milk is let off by taking out the plug in the troughs. All the cream is put into a deep earthen jar, which should be glazed, but not with lead; stone ware is the best. More cream is added every day till there is a sufficient quantity to churn, which in moderate dairies is every two days. It is usual to stir the cream often, to encourage a slight acidity, by which the process of churning is accelerated. This acidity is sometimes produced by the addition of vinegar or lemon-juice; but however this may facilitate the conversion of the cream into butter, we would not recommend it, as the quality is decidedly injured by it, especially of butter which is to be salted. The change by which the butter is separated in a solid form is accompanied by the development of heat in churning. That the state of the atmosphere

with respect to electricity as well as the temperature has a powerful influence on the making of butter, no one can doubt who has paid any attention to the effect of a thunderstorm in a dairy, especially when it occurs at the time of churning. The day may arrive when an electrometer will be found as useful in a dairy as a thermometer is already.

The common method employed to separate the butter from the thinner portion of the cream is by strong agitation. In small quantities this may be done in a bottle, but the common instrument is the *churn*, the chief varieties of which are noticed in a separate article. In the course of an hour's churning, more or less, according to circumstances, small kernels of butter appear; these are soon united by the pressure of the board against the bottom of the churn, and form a mass of solid butter. In these churns the cream is made to revolve with the cask which holds it, and so to fall from side to side and be shaken and broken by this treatment, as it is shaken by revolving beaters in the fixed cask or box in which it is placed. The butter, when separated, is collected with the hand, and placed in a shallow tub for the next operation. The butter-milk is set aside as a drink for pigs, or for domestic use. The butter is still mixed with some portion of butter-milk, but much of its quality for keeping depends on their perfect separation. The most usual way is to spread it thin in a shallow tub, beating it with the hand or a flat wooden spoon, and washing it repeatedly with clear spring water, until all milkiness disappears in the water which is poured off. Some experienced dairymen assert that the butter is deteriorated by much washing, and therefore express the butter-milk by simply beating the butter with the hand, kept cool by frequently dipping it in cold water, or with a moist cloth wrapped in the form of a ball, which soaks up all the butter-milk, and leaves the butter quite dry. This operation requires the greatest attention, especially in warm weather, and no person should work the butter who has not a very cool hand; the less it is handled the better, and therefore a wooden spoon or spatula is much to be preferred.

When it is entirely freed from the butter-milk and of a proper consistency, the butter is divided into portions of the weight required, if it is intended to be sold fresh. The mode of preparing fresh butter for the market is either by making it into *rolls* of two pounds, or into flat round cakes of one pound or half a pound each, which are impressed with some figure cut in a round piece of wood like a large seal, hence called *prints*. The rolls are made oblong with four sides slightly flattened by throwing the lump on a stone or board successively on each of the four sides, and then on the two ends; this requires some dexterity, which is soon acquired, and it is done to avoid unnecessary handling.

To make prints, the butter is first made into balls, and then applied by pressure to the wood, which gives the impressions; the sides are trimmed up along the edge of the wood, and the whole is pressed against a marble or wooden slab, so as to have the impression uppermost, and form a flat cake. The wooden print is readily detached by holding it in the left hand, and giving a smart blow with the right. A hole bored through the centre prevents the adhesion of the butter from the exclusion of the air. In Cambridgeshire butter is made up into rolls a yard long, and passed through a ring of a certain diameter, for the convenience of dividing it into small portions without the trouble of weighing: hence the butter is said to be sold by the yard.

The greatest portion of the butter that is made, especially at a distance from large towns, is immediately salted and put into casks or firkins, which usually contain fifty-six pounds. The quality of the salt used is of great importance; if it be pure, the butter will keep its flavour for a long time, but when it is impure and contains bitter and deliquescent salts, the butter soon becomes rancid. The Dutch are very particular on this point. They use a kind of salt which is made by slow evaporation, and perfectly crystallised; the salt is intimately mixed with the butter. From three to five pounds are sufficient for a firkin of fifty-six pounds. Some dairymen recommend the use of a substitute for plain salt, consisting (for every pound of butter) of half an ounce of dry pounded salt, two drachms of sugar, and two drachms of saltpetre. The casks are made of clean white wood; they are carefully washed inside with strong brine made hot, and rubbed over with salt. The butter being quite dry is pressed close into the cask, a small layer of salt having been first put on the bottom. Every addition is carefully incorporated with the preceding portion. If there is not a sufficient quantity to fill the cask at once, the surface is made smooth, some salt is put over it, and a cloth is pressed close upon it to exclude the air. When the remainder is added, at the next churning, the cloth is taken off, and the salt which had been put on the surface carefully removed with a spoon. The surface is dug into with a small wooden spade, and laid rough, and the newly salted butter is added and incorporated completely. This prevents a streak which would otherwise appear at the place where the two portions join. When the cask is full some salt is put over it, and the head is put in. If the butter has been well freed from all the butter-milk, and the salt mixed with it quite dry, it will not shrink in the cask, and it will keep its flavour for a long time. Should there be an appearance of shrinking, the cask must be opened, and melted butter poured round it so as to fill up the interstices between the butter and the cask; in this way it will not suffer in

its quality. There is a mode of preserving butter for domestic use without salt, in the following manner:—the butter is set in a clean pan over the fire, and melted very gently; it is not allowed to boil, but is heated very nearly to the boiling point. Experience has shown this heat to be attained when the reflection of the white of the eye is distinctly seen on the surface of the butter on looking down into the pan. All the watery particles are then evaporated, and the curd, of which a portion always remains in the butter, and which is one cause of its becoming rancid, falls to the bottom. The clear butter is poured into an earthen vessel and covered over with paper; and a bladder or a piece of leather is tied over the jar to exclude the air. When it is cooled it much resembles hog's lard. It has lost some of its flavour, but it is much superior to salt butter for culinary purposes, and especially for pastry.

The Devonshire method of making butter differs materially from the common process which we have described, and is peculiar to that county. The milk, instead of being set for the cream to rise, is placed in tin or earthen pans, holding about eleven or twelve quarts each. Twelve hours after milking, these pans are placed on a broad iron plate heated by a small furnace. The milk is not allowed to boil, but a thick scum rises to the surface. As soon as small bubbles begin to appear, where a portion of this is removed with a spoon, the milk is taken off and allowed to cool. The thick part is taken off the surface, and this is called *clouted* or *clotted cream*. It is a sweet, pleasant substance, more solid than cream, but not so solid as butter; and is considered as a dainty by all those who have been early accustomed to it. A very slight agitation converts it into real butter; after which it is treated exactly as we have before described. It does not appear that there is any peculiar advantage in the Devonshire method.

Another method of making butter, which is more generally adopted, is to churn the milk and cream together. This method is pursued in parts of Holland, Scotland, and Ireland, and is said to produce a greater abundance of butter from the same quantity of milk. In the Dutch method the milk is put into deep jars in a cool place; each *meal*, or portion milked at one time, being kept separate. As soon as there is a slight appearance of acidity, the whole is churned in an upright churn, which, from the quantity of milk, is of very large dimensions. The plunger is therefore worked by machinery moved by a horse or sometimes by a dog walking in a wheel, which he turns by his weight. When the butter begins to form into small kernels, the contents of the churn are emptied on a sieve, which lets the butter-milk pass through. The butter is then formed into a mass, as described before. In Ireland the process is very similar, but the milk is allowed to arrive at a greater degree of acidity, which is a defect. In Scotland the following method is pursued: the milk is allowed to cool for six hours, and then put into a clean vat. As long as it remains sweet more milk may be added, but not after any acidity is produced. It is then covered and allowed to get sour, till it coagulates at the top; this coagulum is called the *lapper*, which must not be broken till the butter is churned. When the clotted milk is put into the churn, warm water is added, so as to raise the temperature to 70° or 80°, the whole being gradually stirred in. When this is properly conducted, the butter-milk will be very pleasant and wholesome, with a sub-acid taste, the serum and curd not being separated from each other for some time after. The butter is said to be fully equal to that made from cream alone.

Butter is a most valuable article of commerce, and a great source of wealth to those nations which produce it in the greatest perfection. The Dutch has a high character; but the rich pastures in England and Ireland can produce as good butter as those of Holland, if sufficient attention be paid to the minutiae of the dairy, to the purity of the salt used, and especially to cleanliness, for which the Dutch are so remarkable. The quality of the butter depends on some very minute circumstances, which escape the notice of all superficial observers. The smallest particle of putrescent matter, accidentally added, and even mere effluvia, give a turn to the chemical action going on from the moment the milk is exposed to the air, and they taint the cream more or less. The quantity of pure cream which rises when the milk is set in the pans, as well as its quality, is influenced by these circumstances. When the milk curdles before the cream is separated, it is almost impossible to prevent some portion of the curd from being mixed with the butter. In its perfectly fresh state the taste is not affected by this; but the butter will not keep fresh above twenty-four hours, and when salted soon becomes rancid. Thus a greater quantity is produced, but of inferior quality. When cheese is made of the milk from which the cream has been taken, it will be found most profitable not to attempt to take off all the cream by repeated skimming; for more will be gained in the better quality of the cheese than by an increase in the quantity of the butter at the expense of the quality.

It is an acknowledged fact, that such are the niceties of the dairy, that great experience alone can ensure a produce of superior quality: this experience would be more readily acquired if the circumstances were accurately observed and noted. We would recommend to those who have extensive dairies, to mark by the thermometer the temperature of the milk and cream in the different stages of the process, occasionally to test the acidity of the butter-milk by means of alkalies, and to note any peculiarity in the atmosphere by an electrometer. A few observations carefully noted, repeated, and compared, would

throw more light on the true causes which favour or oppose the production of good butter, than all the guesses that have hitherto been made.

The quality of the butter depends materially on the nature of the pasture. The best is made from cows fed in rich natural meadows. Certain plants which grow in poor and marshy soils give a disagreeable taste to the butter. When cows are fed with cut grass in the stable the butter is inferior, except in the case of some artificial grasses, such as lucerne. Turnips and other roots given to cows in winter communicate more or less of a bad taste to butter, which is corrected in some degree by means of a small quantity of water and saltpetre added to the milk; and also, it is said, by giving salt to the cows with their food. But there is no butter made in winter equal to that which is made where the cows are fed entirely with good meadow hay, especially of the second crop, called *aftermath* hay, which contains few seed-stalks. Among the methods recommended for removing a taste, whether of turnips or any other plant, in the food of cows, from their butter, there may be enumerated the use of—(1) Chloride of lime (a drachm to every expected pound of butter, added to the water of the second washing); (2) Saltpetre (a dessert spoonful of a strong solution, added to every two gallons of milk as it comes from the cow); (3) Vinegar (a half-pint added to every gallon of the cream before churning); (4) Hot water (a half pint boiling added to every gallon of milk as it comes from the cow, and allowed to stand for half an hour before setting for cream). This, with cleanliness and care to avoid the use of tainted food, seems to be the most probable of success: the explanation being, that the aroma flies off with the steam, when the milk is thus kept warm for a sufficient length of time.

The yellow colour of fine May butter is frequently imitated artificially by mixing some ground *arnotta* root, or the juice of carrots, with the cream. This is easily detected by the taste of the butter, which is not improved by it, and has not the peculiar flavour of fine grass butter; but in other respects it is a harmless addition. Some cows give a much yellower cream than others, especially the Alderney cows, and the butter made from it is of a peculiarly fine flavour. When a cow has lately calved the milk is also much yellower, but this soon goes off if it be not the natural colour; and the butter made by mixing this with other milk, although of a deeper colour, is not improved by it.

According to the accounts of the produce of butter from different countries and various breeds of cows, it appears probable that, on an average, 4 gallons of milk produce 16 ounces of butter; and to make the feeding of cows for the dairy a profitable employment in England, a good cow should produce 7 lb. or 8 lb. of butter per week in summer, and so much less than that quantity in winter, as that, allowing from six weeks to two months for her being dry before calving, the whole produce of the year may be from 220 lb. to 240 lb. If she produces more she may be considered as a superior cow; if much less, she is below the average. To produce this quantity the pasture must be good, and if we allow three acres to keep a cow in grass and hay for a year, which is not very far from the mark, the butter will produce about 12*l.*, at the distance of 50 miles from London, if it is sold in a fresh state. This, with the value of her calf, does not much more than pay rent and expenses; but the profit is increased by feeding pigs, or making skim-milk cheese.

An inferior kind of butter is made in some cheese dairies from the oily portion of the milk skimmed from the whey, which is set in pans like milk after the cheese has been made. It is sold at an inferior price to labourers, and seldom comes to market. It is totally unfit for salting and keeping. It is known by the name of *whey butter*.

It has been discovered, within the last four years, that cheap butter is occasionally adulterated with *flint*. Flints are ground, and chemically treated until soluble, producing 'soluble silica.' When this preparation is dissolved in water, it becomes a stiff gelatinous body, somewhat resembling strong jelly. This jelly is mixed with butter of low quality, to which fresh salt and colouring matter are added. The compound bears a considerable resemblance to dairy-made butter; but it has not the firmness or bright appearance of the genuine commodity, and is devoid of the richness and wholesome qualities. Of course the object in view is to increase the weight of ordinary butter by the addition of a substance of very small cost. Unfortunately, butter consumers have seldom the skill or facilities for detecting such adulterations.

Considered in its commercial relation, butter is an article of much importance. In Europe, the greatest trade in butter belongs to the more northern nations. The quality of that produced in England and in Holland is the best in the world. A considerable quantity of Dutch butter is exported from Holland; but all the produce of England is consumed at home, in addition to large quantities imported from Ireland and the north of Europe. About the year 1790, the total quantity imported was 200,000 cwts. annually; 215,000 cwts. in 1800; 300,000 in 1810; 365,000 in 1820; 420,000 in 1825. No account of the importations from Ireland can be had later than 1825; the intercourse between the two islands having at that date been placed upon the footing of a coasting-trade. On the other hand, there is no statement of imports of butter from foreign countries of an earlier date than 1801. Therefore, it is only between 1801 and 1825 that the official tables show the real quantity of butter brought into Great Britain. It

was not possible, until recently, to state the quantity of butter exported from the United Kingdom to our colonies and foreign countries, in consequence of the practice at the Custom House of including butter and cheese in the same statement; but this deficiency has been now amended. The shipments of butter so made are entirely of the produce of Ireland; the chief customer is Portugal, and next to that is Brazil.

Understanding, then, that the amount of butter brought from Ireland for consumption in Great Britain cannot now be officially ascertained, we may conclude that all estimates on the subject are merely approximate. Mr. McCulloch, some years ago, estimated the London consumption of butter at about 15,000 tons annually; but we do not know on what data this estimate was made. The Irish butter-trade at Cork is conducted in a remarkable way. There is a committee of members, consisting of buyers, sellers, and factors, to superintend all the dealings. All the butter brought to market is inspected and branded by order of the committee, and is divided into four kinds, according to quality. A sub-committee each morning fixes the price at which each kind of butter shall be sold on that day; the four kinds differ in value about 5s. per cwt. from each other. The butter-buyers are in the habit of advancing money beforehand to the dairy-farmers; insomuch that sometimes a whole season's produce is paid for before any of the butter is made. In average years, about half a million firkins of butter are branded at Cork.

The Board of Trade tables in recent years have presented the following figures relating to the import of butter;—

1856	513,392 cwt.
1857	441,606 "
1858	390,040 "

And the following relating to exports (wholly Irish):—

1856	139,548 cwt.
1857	110,974 "
1858	112,308 "

Various Acts of Parliament were passed in bygone years, with the view of preventing fraudulent practices in the packing of butter; but this kind of legislative interference is now abandoned. At various times during the present century the duty on imported foreign butter varied from 2s. 9d. to 21s. per cwt. The price paid for butter at Greenwich Hospital for about a century past has varied between the limits of 5d. and 14d. per pound.

BUTTER OF ANTIMONY. [ANTIMONY, TERCHLORIDE OF.]

BUTTER OF TIN. [TIN, BICHLORIDE OF.]

BUTTER OF ZINC. [ZINC, CHLORIDE OF.]

BUTTERS (in pharmacy) was the name formerly given to certain hydrochlorates of the metals, such as antimony, arsenic, bismuth, tin, and zinc. Precipitated sulphur likewise was termed butter of sulphur. These designations are now nearly obsolete.

BUTTON-MANUFACTURE. This useful little appendage to dress is made of nearly every variety of material. Gold, silver, brass, copper, steel, iron, pewter, mother-o'-pearl, hard wood, bone, ivory, horn, leather, gutta-percha, vulcanised india-rubber, paper, glass, silk, wool, cotton, linen, thread, are all formed into buttons; and the manufacture is carried on very largely.

The varieties of buttons may be reduced to four, namely, 1, those *with shanks*; 2, those *without shanks*; 3, those on *wire moulds* (or rings); and 4, buttons *covered* with silk, cloth, or other material.

Metal buttons with shanks are generally punched out of a plate of brass having rather less zinc in its composition than ordinary brass. The discs so punched out, after having their edges trimmed to take off the burr, are ready for the shank. The shanks are made of wire by a most ingenious machine invented by Thomason of Birmingham. A coil of wire is placed in the machine, one end of which gradually advances to a point where a pair of shears cuts off a piece of the requisite length; a stud then presses against the middle of the piece and forces it between the two jaws of a vice into a staple-like form: the jaws compress it so as to form the eye of the shank; a little hammer then strikes the end and makes it level; and another movement finally drops it complete into a box. The shanks being placed upon the disc in their proper position, and kept there by a bent flat strip of iron, a small piece of solder is placed at the foot of the shank. In this state a hundred or more are put upon an iron plate and heated in an oven till the solder runs and fixes the shank. They are then turned separately in a lathe, the chuck of the lathe being so formed as to allow the buttons to be put in and taken out with great facility. The gilding is performed (or rather *was*, before the invention of electro-gilding) with an amalgam of gold and mercury, about the consistence of butter: five grains of gold are sufficient for a gross of buttons.

White metal buttons, such as those on soldiers' dresses, are cast in moulds, containing ten or twelve dozen, and the shanks are placed in the moulds previous to casting, so that when the buttons are cast the shanks are fixed at the same time.

Mother-o'-pearl buttons are cut out of the pearl shell by means of a small cylindrical saw, that is, a tube of steel with its edge cut into teeth. This tubular saw has a pulley on the tube, and is made to revolve rapidly after the manner of a lathe; the shell is pressed up

against it, and thus the circular disc for the button is quickly cut out of the shell. The discs are turned in a lathe; and if the shell be thick, two are produced by splitting it. As the shanks cannot be soldered in, and they would not look neat if riveted through the button, a hole is turned about half way through, the hole being wider at the bottom than at the top, or, as it is called, dovetailed. The stem of the metal shank is just the size of the smallest part of the hole, and the stem is made a little hollow by drilling a conical hole up it, so as to leave the metal very thin at the edges. The shank being now put into the dove-tailed hole, a slight blow with the hammer spreads the thin edge of the stem under the dove-tailed edge of the hole; and thus the shank is firmly fixed. Mother-o'-pearl buttons are sometimes ornamented with eccentric circles, flutes radiating from the centre, &c., all of which are executed in the lathe by means of an eccentric chuck and slide rest.

Buttons without shanks are made of mother-o'-pearl, wood, bone, metal, &c., the metal ones being stamped and the rest turned. They have four holes through which the thread is passed to fix them on the garment. These holes are stamped in metal buttons, but they are drilled in those which are made of other materials. The holes are drilled while the buttons are in the lathe; four long drills are made to converge towards the button, and thus the four holes are all drilled at once.

Buttons on wire moulds are merely wire rings covered with thread by machinery which entwines the thread over the ring from its centre.

Covered buttons. Although many beautiful specimens of metal buttons have been produced by the manufacturers, still metal buttons may be said to be in great measure superseded by covered buttons. The stimulus being thus given, a great deal of ingenuity has been shown in the manufacture of covered buttons, and a number of patents have been obtained for the inventions: the following two plans will give a general idea of the principles of their construction. In one plan a metal disc is punched out of thin iron plate, which by subsequent punches has its edges turned up and then bent a little inwards: this is done to form the body of the button. Another smaller disc, capable of lying within the edges of the above, has a round or oval hole in the centre: this is to form the back. A circular piece of the stuff called florentine is then wrapped round the larger disc, and the edges are brought over and pressed into the hollow; the smaller disc or back is pressed into its place, and the turned-up edges of the face being compressed on the back, the whole becomes firmly fixed together; and the cloth protruding through the hole in the back affords the means of fixing it to the garment. In the other plan, which produces a very neat button, the disc for the body is left flat, and the back is a small circular disk with a round hole in the centre, but the outer edge is cut into eight sharp triangular points like a little star. These points are bent to a little less than a right angle to the disc, so that the points incline a little inwards. Besides these two metal discs, three pieces of paper and two pieces of cloth are necessary, so that the button consists of no less than seven separate pieces, which are put together in the following order:—1st. On the piece of florentine which forms the outer covering is laid a piece of paper of the same size; on this the iron disc forming the body; on this another piece of paper the same size as the body; on this another piece of paper crumpled up into a little pellet to help to form the shank; on this a piece of coarse cloth; and finally the metal back. In putting on the back the florentine is gathered up over the whole of the materials, and then the points of the back are pressed into it; and as the points of the back are bent a little inwards (as was mentioned above), the consequence of the pressure is, that as they enter the cloth they bend more and more inwards, and thus form eight little *hooks* which very neatly and effectively hold the whole together. The little paper pellet makes the cloth protrude through the hole in the back, and forms the cloth shank by which it is attached to the coat. Almost the whole of these processes were originally performed by punches of various forms; but a patent was afterwards secured for a most ingenious machine to do the whole of the work. By placing two plates of iron, a roll of florentine, a roll of cloth, and three rolls of paper, and by setting the machine in motion, the whole of the seven parts of the button are cut out, put in their respective positions, and combined together into a perfect button.

A very beautiful and perfectly novel steel button was some years ago produced by Mr. Barton of the Royal Mint. It was intended for court dresses, being far too delicate and too expensive for ordinary purposes. By means of most accurate dividing machinery, a number of groups of fine lines are engraved on the button, the graving point being the splinter of a diamond: the machine is so accurate, that 10,000 lines can be drawn within the inch. The groups of lines may be disposed in triangles or hexagons, after the manner of a honeycomb, or in any other form at the option of the artist, or the lines may be made to cross each other in any direction. The pattern is comparatively of little importance, the beautiful effect being produced by the brilliant reflection of the light, which exhibits all the colours of the rainbow (on the principle of Newton's rings) in playful clouds like mother-o'-pearl, or in intense colour like the ruby or the emerald. This invention, however, never came extensively into use.

A singular method was introduced a few years ago, of imitating covered cloth buttons by a layer of flock, such as is used in paper

hangings. In the first place, thin sheets of metal are coated on one side with copal varnish thinned with turpentine, and coloured according to the colour of the flock to be employed. After being heated in an oven to 150° Fahr., and then allowed to cool, the surface is coated with a kind of paint formed of white lead, linseed oil, gold size, and colouring matter. While in this wet state, a quantity of flock is sifted over the surface, and allowed to remain on it twelve hours, by which time a film of flock will have adhered firmly to the metal. The loose flock being shaken off, the sheet is fitted to be cut up into collets or discs for the backs of buttons, to be made in the usual way.

Mr. Prosser's method of making buttons and other small articles of compressed clay was patented in 1840. Clay, clayey earth, or clay combined with a small portion of flint or felspar to give it hardness, is thoroughly dried and ground to a fine powder. The powder is passed through a sieve having about two thousand perforations in a square inch: all particles too large to pass through the perforations being rejected. For some coarser purposes a coarser sieve may be used. Buttons and other small articles are made of this powder by dies, or moulds, and a fly-press. The fly-press is firmly secured to a strong bed, or frame; and a die carrying on its under face the form in reverse (that is, hollow instead of relief), proposed to be given to the top of the button, is screwed to the follower of the press. A second tool or die of a kind of T shape, with an impress of the back of the button, fits loosely into a corresponding recess in the bolster. Below the press there is a treadle supported on a fulcrum near its centre, from one end of which a rod passes up through a small hole in the bolster to the lower die or tool. The hollow or recess in the bolster in which this tool rises and falls is of such a depth as to be an exact measure of the quantity of powder necessary for the formation of a button. The hollow in the mould being filled with powder, and the powder squared off to an exact level with the top of the mould, such power is applied to the press as will bring down the tool with a force of about 200 lb. on the square inch, upon the powder lying in the mould. The powder is by this means compressed into a very dense, hard, and durable substance, having on its surface the device imparted to it by the die. If the button is to have a metallic shank attached to it, a recess is formed at the back of the button for its reception, by a corresponding projection on the face of the lower die. If the button is to have holes similar to a brace-button, the dies must have such projections as will form these holes while the powder is being pressed into the mould. In the course of a year or two after this patent was obtained, no less than 5000 gross of these buttons were made weekly, at Minton's porcelain works in Staffordshire.

The Vicomte de Serionne took out a patent in 1850, for a somewhat complicated mode of making buttons, which should have a sort of crystalline appearance. They are made of felspar, basalt, lava pumice, granite, or flint. These minerals, or the one to be adopted, is reduced to powder, and made into a paste with salt and flour; the paste is pressed into a mould, of which the upper and under parts give the device to the button; and by subsequent modes of treating the surface, the button assumes either a transparency, or an agate-like opacity.

It would be quite useless to endeavour to describe the numerous patents for button-making introduced every year in England; they differ in points which, though important to manufacturers, are of little interest to general readers. One curious invention, patented a few years ago, was for ornamenting metal-buttons by printing a design from blocks or rollers, with an ink of sulphate of copper and tin, and then varnishing.

Birmingham is the great seat of the button manufacture in this country. By the census of 1851, there were 770 males under twenty years of age, 1350 above that age, 1265 females under twenty years of age, and 1595 of twenty years of age and upwards, a total of 4980 persons employed in that town; while the total number employed in the trade in England and Wales was but 2988 males and 3950 females of all ages; and in Scotland there were but 11 males and 4 females of all ages engaged in the manufacture.

BUTTRESS, a projecting support to the exterior of a wall, most commonly applied to churches in the Gothic style, but also to other buildings, and sometimes to mere walls. Buttresses, in the sense in which the term is commonly used, were not employed in Greek and Roman buildings, the external support being obtained by pilasters, or some other structural feature, to the presence of which, as an additional support, was given as little prominence as possible. Norman or Romanesque buttresses, which came into use probably from the time of the decay of Roman architecture, are plain broad faces, slightly projecting from the wall of the building to which they belong. In appearance they are very similar to the shaft of a pilaster, from which they most probably derive their origin. The top of these buttresses is terminated by an inclined plane or water-table, moulded underneath on the front face only. The bands which often occur in Norman buildings as a sort of capping to the basement of the wall are often continued round the sides of the buttress, thus making the lower part of the buttress as it were a pedestal to the upper part, or more properly to the pilaster. Unlike the buttresses of pointed architecture, those of the Norman period are not divided into stages diminishing in width as

they ascend, but continue of the same width to the top; and they are carried no higher than the cornice, under which they usually finish with a slope. In later Norman and transition buildings, buttresses are sometimes ornamented at the angles with columns, as at Castle Rising castle, Norfolk, Glastonbury Abbey, &c. But these decorations are sometimes of a later date. An additional resemblance to the Roman pilaster appears in these buttresses when they are found with a narrower face projected on the broader buttress. Castle Rising and Norwich castles contain good examples of Norman buttresses.

Of First Pointed or Early English buttresses, which immediately succeeded the former, Mr. Rickman distinguishes four kinds. The *first* is a flat buttress, narrower than the Norman, with mouldings more delicate, but very similar to, and hardly to be distinguished from the Norman. The *second* is a buttress projecting at times nearly as

A, Norman Buttress. B, Early English Buttress. C, Decorated English Buttress.

much as its breadth; at others, more than the breadth of the buttress. These buttresses sometimes are without set-offs, or have only one forming a division in the whole height. There are buttresses at Salisbury which belong to this class, and are highly enriched with niches and decorated with ornaments, but they have a very weak appearance. The *third* kind consists of long slender narrow buttresses, with a considerable projection, divided into several heights; they occur in some towers. The *fourth* kind of buttress of this period, and perhaps the latest, is divided into stages or divisions, receding one behind the other; but this also is not common. Like all the former, it is finished with a triangular, or rather acute-angled top, similar to the roof and gable ends of a building. These two last kinds are very similar in character.

Towards the close of this period, flying buttresses were first constructed, being thrown from the side aisle buttresses to the buttress of the nave and choir. Salisbury and Chichester cathedrals afford excellent examples; but flying buttresses did not become common till the next period of Gothic architecture. Early English buttresses have generally pyramidal tops; the sides of these buttresses are sometimes splayed at the edges, with pedestal-like bases. The shaft also is at times divided into one or more divisions, as at Lincoln. Occasionally the buttresses are very slender and carried up to a great height, becoming in fact rather ornamental features than supports, as at Beverley Minster, and the east end of All Saint's, Stamford. Beverley Minster has columns at the angles of the buttresses, with a niche in the pyramidal head.

The Middle Pointed or Decorated English buttresses which succeeded these, present many varieties; they exhibit some of the leading features of their predecessors, but are generally highly enriched. They are almost invariably divided into stages; are enriched with panels, niches, crocketed canopies, and, in large buildings, very frequently terminate in pinnacles. The triangular heads are commonly enriched with cusps. These buttresses, when used at the angles of buildings, are often applied diagonally to the angle, as at St. Mary Magdalene, Oxford. Examples of rich buttresses of the decorated style occur in the west front of York Minster; Exeter Cathedral; Malmesbury Abbey church; at the east end of Howden church, Yorkshire; at Bottisham, Cambridge-

shire; Redgrave, Suffolk; Gadsby, Leicestershire; and at the east end of Walsingham Priory. This last is almost in the perpendicular style, which immediately followed the decorated.

Third Pointed or Perpendicular English buttresses vary chiefly from those of the style which preceded them in that they are generally higher,

Perpendicular English Buttress.
Woolpit, Suffolk.

Decorated English Buttress.
Waltham Cross.

project more in proportion to their width, are of more numerous stages, are commonly panelled, and have the edges left sharp instead of, as hitherto, being chamfered. On the whole, however, they display less freedom of design. The heads of buttresses in the earlier part of this period are triangular, but are not acute-angled, as in those of the preceding century, and have crockets of very ornate character. In later examples, buttresses have sometimes flat terminations, which serve as pedestals for figures, as at King's College chapel, Cambridge; St. George's, Windsor; Beauchamp chapel, Warwick, and the Lady Chapel at Peterborough. Flying buttresses of extraordinary dimensions and elaborateness occur in French Gothic churches, as at Amiens, Rheims, St. Ouen, &c. Octagonal turrets are sometimes used as buttresses, as in Henry VII.'s chapel at Westminster, from which spring

the flying buttresses. The most superb of this kind ever executed in this country belong to this edifice.

Flying Buttress, from Henry VII.'s Chapel, Westminster.

(Ample details respecting buttresses will be found in Brandon's 'Analysis of Gothic Architecture'; Parker's 'Glossary'; the 'Dictionary of the Architectural Publication Society'; and the works of Britton, Bloxam, Pugin, Paley, Chapuy, De Caumont, Le Duc, &c.)

BUTYL (C_4H_9), *Valyl*, *tetryl*. The radical butyl was first discovered by Kolbe, among the substances produced by the electrolysis of valerianate of potash. Its formation is hence quite analogous to that of the radical methyl (C_2H_5), from acetate of potash. [METHYL.] It has also been obtained by Wurtz, by the action of potassium upon iodide of butyl. When pure, it is a limpid oil with an agreeable etherial odour, of the sp. gr. 0.694. It boils at 226° Fahr., and distills without alteration. It is only attacked with difficulty by oxidising agents. By the action of chlorine substitution products are formed.

Butyl is contained in a numerous family of organic substances, of which the following are the most important:—

Butylic alcohol (C_4H_9O). This substance is a member of the series of homologous alcohols of which ordinary alcohol is the type, and the general formula for which is $C_nH_{2n+2}O$. It was discovered by Wurtz as a constituent in varying quantities in certain crude alcohols resulting from the fermentation of beetroot molasses. To obtain it, the crude alcohol is submitted to fractional distillation, and the distillate between 221° Fahr. and 239° Fahr. separately collected. This is then treated with potash and distilled, the distillate dehydrated over caustic lime, then re-distilled, and the product thus obtained rectified. What now passes over between 226° Fahr. and 230° Fahr. is pure butylic alcohol.

It is a colourless, highly-refracting liquid, with an odour resembling amylic alcohol, but more vinous. It has the sp. gr. 0.803, and it boils at 228° Fahr. It is more soluble in water than amylic alcohol.

Its formation from sugar may be thus expressed—

Butylic alcohol is homologous with common alcohol, and in its chemical relations and physical properties it presents, with regard to that substance, all the regular gradation of properties which characterises a true homologue, and accordingly we view it as containing the radical *butyl*, C_4H_9 , of which it is the hydrated oxide (C_4H_9O, HO). [ALCOHOLS.] Like vinic alcohol it undergoes a series of changes under the influence of various reagents, and the substances produced bear the most perfect resemblance to those formed under the same circumstances from alcohol. It will not therefore be necessary to do more than briefly mention them.

When potassium acts upon butylic alcohol, hydrogen is liberated, and a crystalline product is obtained, *butylate of potash* (C_4H_9O, KO). By the action of soda-lime at a high temperature, hydrogen is liberated, and an alkaline butyrate is formed. Pentachloride of phosphorus attacks butylic alcohol energetically, and forms *chloride of butyl* (C_4H_9Cl), a colourless liquid of an etherial odour, which boils at about 160° Fahr.

This compound is also formed when butylic alcohol is treated with

hydrochloric acid. By the action of the chloride of butyl on sulphide of potassium, *sulphide of butyl* (C_4H_9S) is produced; and by its action on hydrosulphide of potassium, *hydrosulphide of butyl* (C_4H_9S, HS), the mercaptan of butylic alcohol is formed.

The action of bromide of phosphorus (PBr_3), and of iodide of phosphorus (PI_3), on butylic alcohol is analogous to that of chloride of phosphorus, and the *bromide of butyl*, C_4H_9Br , and *iodide of butyl*, C_4H_9I , which are formed, closely resemble the chloride.

The action of iodide of butyl on ammonia, like that of iodide of ethyl on the same substance, gives rise to the formation of various compound ammonias, in which one or more equivalents of hydrogen are replaced by the radical butyl (C_4H_9). One of these, *butylamine*,

ethylamine, methylamine, and propylamine, in the basic part of Dippel's animal oil.

By acting with iodide of butyl on various silver salts, Wurtz obtained a number of compound butylic ethers. The *carbonate of butyl* (C_4H_9O, CO_2), *nitrate of butyl* (C_4H_9O, NO_3), *acetate of butyl* ($C_4H_9O, C_2H_3O_2$), were obtained in this manner. They strongly resemble the corresponding ethyl compounds.

Cyanide of butyl ($C_4H_9C_2N$). Valerianate of ammonia, by the action of anhydrous phosphoric acid, loses four equivalents of water, and is converted into this substance:—

It is also obtained, along with other products, by the oxidation of gelatine, and of caseine, by means of chromic acid. It is a colourless, highly refracting liquid, of a burning aromatic odour and bitter taste; its spec. gr. is 0.81, and it boils at 257° Fahr. In its chemical deportment it resembles the cyanides of the other alcohol radicals. By boiling with potash it is converted into valerianic acid and ammonia.

By the careful addition of sulphuric acid to butylic alcohol, so as to avoid too great an increase of temperature, *sulphobutylic acid* ($C_4H_9OSO_3, HO SO_3$) is obtained, corresponding to sulphovinic acid. It forms salts which crystallise well, and bear the most striking resemblance to the sulphovinates.

If butylic alcohol be treated with excess of chloride of zinc, gaseous and liquid products are formed; the gases contain, among others, *butylene* (C_4H_8), homologous with olefiant gas, and *hydride of butyl* (C_4H_9H), homologous with hydride of ethyl.

Butylene has also been obtained by Faraday, among the products formed when fatty acids are passed through a red-hot tube. Kolbe also obtained it by the electrolysis of valerianate of potash. At the ordinary temperature it is a gas of the sp. gr. 1.926. It combines with chlorine in equal volumes, forming a colourless, limpid, aromatic liquid, which boils at 253° Fahr. Its formula is $C_4H_8Cl_2$; it is the chloride of butylene, and is homologous with the chloride of ethylene, or Dutch liquid, $C_2H_4Cl_2$. In its chemical deportment it perfectly resembles that substance. Bromine also combines with butylene, forming *bromide of butylene* ($C_4H_8Br_2$).

If, in the preparation of sulphobutylic acid, the temperature be not kept down, a violent reaction ensues, with the disengagement of sulphurous acid, and formation of various oily hydrocarbons, which appear to be polymeric with butylene.

Butylic ether ($\begin{Bmatrix} C_4H_9 \\ C_4H_9 \end{Bmatrix} O_2$) has not yet been prepared in a pure state. It is formed by the action of iodide of butyl on a solution of butylate of potash in butylic alcohol.

BUTYLAMINE. [BUTYL.]

BUTYLIC ALCOHOL. [BUTYL.]

BUTYLIC ETHER. [BUTYL.]

BUTYLIC GROUP. *Tetrylic Group*. This group of organic compounds belongs to the VALERIANIC SERIES. The principal substances contained in this group are described under the head of BUTYL.

BUTYLUREA. [UREA.]

BUTYRAL. [BUTYRIC ACID.]

BUTYRALDEHYDE. [BUTYRIC ACID.]

BUTYRAMIDE. [AMIDES; BUTYRIC ACID.]

BUTYRATES. [BUTYRIC ACID.]

BUTYRIC ACID ($\begin{Bmatrix} C_4H_9 \\ H \end{Bmatrix} O_2$). This substance occurs in nature both in the free state and in combination with bases. In butter it exists, in combination with glycerine, in the form of butyrine. This,

which is a neutral substance, becomes decomposed on being kept for some time, more especially in a warm atmosphere, butyric acid being liberated, which then imparts to the butter its peculiar rancid odour. Butyric acid is a frequent product of the action of oxidising agents on organic substances, and it occurs not less frequently as a product of putrefaction and fermentation. Grape sugar, under certain circumstances, undergoes a peculiar fermentation, by which it is converted into a substance, lactic acid, isomeric with itself. If the fermentation, instead of being arrested at this stage, be allowed to proceed, another change takes place, and the lactic acid becomes entirely changed into butyric acid. It is on this process of fermentation that the best methods of preparing butyric acid are based. The method originally described by Pelouze and Gelis has since been essentially improved by Bensch, by whom the following process has been given.

Six pounds of cane sugar and half an ounce of tartaric acid are dissolved in 26 lb. of boiling water, and the mixture left for a few days to allow the cane sugar to become converted into grape sugar. To this mixture, about half a pound of decayed cheese diffused in a gallon of sour skim milk, together with 3 lb. of finely-powdered chalk, are added, and the whole exposed in a warm place, the temperature of which must not exceed 85° — 95° Fahr. The mass is stirred daily, and generally solidifies in eight or ten days to a mass of lactate of lime. On standing, this gradually becomes more liquid; carbonic acid and hydrogen gases escape; and when, after five or six weeks, the disengagement of gas ceases, the whole of the sugar has passed first into lactic acid, and subsequently into butyric acid, which is present as butyrate of lime.

The change may be thus expressed:—

The solution of butyrate of lime is then mixed with an equal volume of water, and a solution of 8 lb. of crystallised carbonate of soda is added. The liquid is filtered off from the precipitated carbonate of lime, evaporated to a smaller bulk, and dilute sulphuric acid added. This liberates the butyric acid, which rises to the surface as a dark oily layer, and is removed by means of a siphon. It is then dehydrated by chloride of calcium, and purified by fractional distillation.

When pure it is a colourless, mobile liquid, a little lighter than water, with an odour at once like acetic acid and rancid butter, and an acrid and burning taste. It boils at 327° Fahr., and distils without change. Its vapour is inflammable, burning with a blue flame. When exposed to the great cold produced by solid carbonic acid and ether, it crystallises in large plates. It attacks the skin and produces blisters, like the most powerful acids.

It is not attacked by sulphuric acid in the cold, and only feebly when hot. Butyric acid dissolves in nitric acid without alteration, but by prolonged boiling it is oxidised, and converted into succinic acid.

The action of chlorine on butyric acid gives rise to new acids, *Bichlorobutyric acid* ($C_4H_6Cl_2O_4$), and *Quadrichlorobutyric acid* ($C_4H_4Cl_4O_4$), which contain 2 and 4 equivalents of chlorine in the place of the same number of equivalents of hydrogen.

The formula of butyric acid is $C_4H_8O_4$, and it is isomeric with acetate of ethyl, and propionate of methyl. By its chemical composition and relations, and by its physical properties, butyric acid belongs to the series of volatile fatty acids of the general formula $C_nH_nO_2$ —it is hence homologous with formic and acetic acids, and it bears the greatest resemblance to those acids, both in its properties, and in those of its compounds; the difference being no greater than might be predicated from its higher position in the series. Analogous to acetic acid we may consider butyric acid as containing the organic radical *butyryl* ($C_4H_7O_2$), and butyric acid would thus be the hydrated oxide of butyryl ($C_4H_7O_2O, HO$).

The butyrates are monobasic, their general formula is $C_4H_7MO_4$, or $MO, C_4H_7O_3$. When dry, they are inodorous: for the most part they are soluble in water and crystallisable. *Butyrate of soda* ($NaO, C_4H_7O_3$), and *butyrate of potash* ($KO, C_4H_7O_3$) are deliquescent salts. *Butyrate of baryta* ($BaO, C_4H_7O_3 + 2aq$) crystallises in long flattened prisms, perfectly transparent; when thrown on water, it assumes curious gyratory movements. *Butyrate of lime* ($CaO, C_4H_7O_3$) forms transparent fusible needles: it presents in water the same phenomena as the baryta salt. *Butyrate of copper* ($CuO, C_4H_7O_3 + aq$) forms beautiful green crystals of the monoclinic system.

Butyrate of ethyl, or *butyric ether* ($C_4H_9O, C_4H_7O_3$) is obtained by distilling a mixture of butyric acid, alcohol, and sulphuric acid. In a state of purity it is a colourless, inflammable liquid, with a peculiar odour resembling pine-apples. A solution of this ether in alcohol is used in confectionery under the name of *pine-apple oil*. The peculiar flavour of old rum is due to the presence of a small quantity of this ether.

Alkalies decompose butyric ether into a butyrate and free alcohol.

When agitated in a flask with ammonia for some time, it decomposes into alcohol, and *butyramide*.

Butyramide crystallises in brilliant white pearly tables. It is ammonia, in which 1 eq. of hydrogen is replaced by the radical butyryl

When butyric acid is heated for some time with glycerine, combination takes place with elimination of water; according to the circumstances of the experiment, three different compounds may be formed, *monobutyryne*, *dibutyryne*, and *tributyryne*. Their formation may be thus expressed:

They are neutral oils of strong odour and pungent bitterish taste. Probably tributryne is that which is present in butter.

When butyramide is treated with anhydrous phosphoric acid, it loses 2 eq. of water, and is converted into *butyronitrile* or *cyanide of propyl*.

This is an oily liquid, boiling at 247° Fahr. It is also found among the products of oxidation of some organic substances.

Chloride of butyryl ($\text{C}_4\text{H}_7\text{O}_2\text{Cl}$), is prepared in an entirely analogous manner to the corresponding acetyl compound, by the action of oxychloride of phosphorus or butyrate of soda.

It is a colourless, highly refracting liquid, heavier than water, and fuming strongly in the air. It boils at 203° Fahr. It decomposes with water into butyric acid, and hydrochloric acid. By ammonia it is

converted into *butyramide* ($\text{N} \begin{Bmatrix} \text{C}_4\text{H}_7\text{O}_2 \\ \text{H} \\ \text{H} \end{Bmatrix}$) and by aniline in an analo-

gous manner into *butyranilide* $\text{C}_{20}\text{H}_{13}\text{NO}_2 = \text{N} \begin{Bmatrix} \text{C}_4\text{H}_7\text{O}_2 \\ \text{C}_6\text{H}_5 \\ \text{H} \end{Bmatrix}$ a substance which crystallises from alcohol in beautiful pearly laminae.

By the action of chloride of butyryl on butyrate of soda, anhydrous butyric acid ($\text{C}_4\text{H}_7\text{O}_2$) is formed. It is a colourless mobile highly refracting liquid, of a peculiar pleasant odour, lighter than water, by which it is slowly converted into hydrated butyric acid.

Two compounds are known which have the composition of the aldehyde of butyric acid. The one was obtained by Chancel among the products of the destructive distillation of butyrate of lime. These products may be separated by fractional distillation; the most volatile is *butyral*, a liquid boiling at 203° Fahr. It has the composition of butyric aldehyde ($\text{C}_4\text{H}_8\text{O}_2$), and many of the properties of an aldehyde; by oxidation it is converted into butyric acid, it reduces solutions of gold and silver, and combines with alkaline bisulphites; but it forms no definite compound with ammonia.

Butyraldehyde ($\text{C}_4\text{H}_8\text{O}_2$). The true butyric aldehyde, or hydride of butyryl occurs among the products formed by the oxidation of caseine, albumen, and gelatine. It differs, from its isomer butyral, in its boiling point, which is between 158° and 167° Fahr., and in forming a very well defined compound with ammonia $\text{C}_4\text{H}_7\text{O}_2 \cdot \text{NH}_3$

Butyrone ($\text{C}_{14}\text{H}_{14}\text{O}_2$), the keystone of the butyric series, was also obtained by Chevreul among the products of the destructive distillation of butyrate of lime. It is homologous with acetone and propione, and represents butyraldehyde in which 1 eq. of hydrogen is replaced by propyl (C_3H_7). It boils at 291° Fahr., and is oxidised by nitric acid to *nitropropionic acid* ($\text{C}_6\text{H}_5(\text{NO}_4)\text{O}_4$).

BUTYRIC ETHER. [BUTYRIC ACID.]

BUTYRIC FERMENTATION. [FERMENT.]

BUTYRIC GROUP. A family of organic compounds, belonging to

the BUTYRIC SERIES of Gerhardt's system of classification. The most important compounds belonging to this group are described under the head of BUTYRIC ACID.

BUTYRIC SERIES. This series of organic compounds contains a number of bodies more or less closely related to one of the acids contained in rancid butter, and to which the name of butyric acid has been given. The butyric series comprehends the following three groups:—

1. Propylic or Tritylic Group.
2. Butyric Group.
3. Pyrotartaric Group.

BUTYRINE, a peculiar oleaginous matter, discovered by Chevreul, in butter, in which it exists combined with oleine and stearine, and a very small quantity of butyric acid. In order to prepare it, butter must be first separated from butter-milk by melting and pouring it off, and the butter thus purified is to be allowed to cool very slowly in a deep porcelain vessel, and then it is to be exposed for some days to a temperature of 66° Fahr.; by this treatment a large quantity of stearine is separated, crystallised in small grains, and an oily compound is obtained, which is to be carefully filtered, and then put into a glass vessel with an equal weight of alcohol of specific gravity 0.796, and kept at the temperature of 66°. The mixture is to be frequently shaken during 24 hours, and then the alcohol is to be poured off, and the insoluble portion set aside. By carefully distilling the alcohol, an oil rich in butyrine is left, but as it is slightly acid it is to be treated with carbonate of magnesia: the butyrate of magnesia thus formed being very soluble in water, is rapidly separated; the remaining fatty matter is then to be treated with alcohol, and this being distilled the butyrine is left pure.

The properties of butyrine are, that at 66° it is very fluid, and it congeals at about 32°. Its smell resembles that of heated butter. It is generally yellowish, but this colour is not essential, for some kinds of butter yield it almost colourless. Its specific gravity is 0.908; it is insoluble in water; but alcohol of specific gravity 0.822, when boiling, dissolves it in all proportions. When two parts of butyrine are combined with ten parts of boiling alcohol, the mixture on cooling becomes turbid; but when twelve parts of butyrine are similarly treated with the same quantity of alcohol, the mixture remains transparent even after it has become cold. During distillation the alcoholic solution becomes very slightly acid; and the residue contains traces of butyric acid. Butyrine readily saponifies, and is then converted into glycerine, and butyric, capric, caproic, margaric, and oleic acids.

The substance thus obtained from butter is obviously a mixture, but the recent researches of Berthollet have shown that pure butyrine may be prepared by passing a current of hydrochloric acid gas into a mixture of butyric acid and glycerine; according to the conditions of the experiment, one or other of the following compounds is formed [BUTYRIC ACID]:—

Monobutyryne	$\text{C}_{14}\text{H}_{14}\text{O}_8$
Dibutyryne	$\text{C}_{22}\text{H}_{20}\text{O}_{10}$
Tributyryne	$\text{C}_{30}\text{H}_{26}\text{O}_{12}$

BUTYRONE. [BUTYRIC ACID.]

BUTYRONITRIL. [BUTYRIC ACID.]

BUTYRUREIDE. [UREA.]

BUTYRYL. [BUTYRIC ACID.]

BUTYRYL, HYDRATED OXIDE OF. [BUTYRIC ACID.]

BU'XINE, a vegetable alkaloid obtained from the box-tree (*Buxus sempervirens*). It is difficult to procure this substance colourless; and it has generally the appearance of a translucent deep brown-coloured mass. Its taste is bitter, it excites sneezing, and is insoluble in water, but is dissolved in small quantity by alcohol and ether. It acts as other alkalies on reddened litmus paper, and forms neutral salts with the acids, which are more bitter than the base itself; and the solutions give gelatinous white precipitates with potash. Sulphate of buxine crystallises confusedly. This alkaloid is contained in every part of the box-tree, and the bark gives nearly one per cent. of it.

BUXTON WATERS. The waters of Buxton belong to the northern or Derbyshire thermal springs, which have a lower temperature than those of the southern or Gloucestershire and Somersetshire group, except Bristol. They are of the calcareous class of mineral waters, and rise in a valley situated on the west edge of the great limestone range, which extends through the county of Derby from Castleton southwards, comprising what is termed the Peak Forest. The surface of this district is occupied, according to Farey, by the outcrop of four strata of limestone and three beds of amygdaloid or toadstone, interposed between the limestone strata; but it should be observed that this division of the limestone by regular beds of toadstone has been stoutly denied, and at present is not generally received. Above the upper stratum of limestone is a coarse sandstone or millstone grit, considered by many as the inferior bed of the coal formation, which occupies the whole country E. and N. of this district. Buxton is immediately to the S. of the outgoing of the lowest stratum of limestone. The limestone, which is of a whitish or yellowish colour, is full of encrinures, madrepores, and other organic remains. The direction of the strata is generally N. and S. A remarkable fault is observed in the valley of the Derwent, at Matlock; the upper bed of limestone on

the W. side of the valley is brought down below the second bed on the E., and the upper bed of toadstone on the one side is nearly on the same level with the second bed on the other. The fault is said to extend N. as far as Buxton, where it takes a N.W. direction to North Bradwell, and terminates at Litton near Tideswell; but both the direction and extent of this fault have been much disputed. It is in the course of this fault that the thermal springs of Buxton and Matlock are found. That of Buxton possesses the higher temperature, namely, 82° Fahr., which never varies at any hour of the day or season of the year. This water has been long celebrated for its medicinal virtues. It is more remarkable for the nature of its gaseous impregnations than for the quantity or nature of its saline ingredients.

"The following analysis gives the amount and nature of the solid ingredients in one imperial gallon of the water, at 60°:—

	Grains.
Silica	0.666
Oxide of iron and alumina	0.240
Carbonate of lime	7.773
Sulphate of lime	2.323
Carbonate of magnesia	4.543
Chloride of magnesium	0.114
Chloride of sodium	2.420
Chloride of potassium	2.500
Fluorine (as fluoride of calcium)	a trace
Phosphoric acid (as phosphate of lime).	a trace
	20.579

On examining the water, there were found present carbonic acid and nitrogen, in addition to the solid ingredients. One gallon of the water was found to contain altogether 13.164 grains of carbonic acid; but of this quantity, 5.762 grains were due to the carbonates of lime and magnesia, and therefore only 7.402 grains could be considered free. The carbonates of lime and magnesia are present as bicarbonates, or as carbonates dissolved in carbonic acid, and 5.762 grains of carbonic acid would require to be added for this purpose. Hence, of the 7.402 grains, or 15.66 cubic inches, of gaseous carbonic acid in the water, only 1.640 grain, or 3.47 cubic inches, can be considered free and uncombined. The nitrogen in the water could only be present in solution, and not in combination. The gas therefore consists entirely of carbonic acid and nitrogen, with a trace of oxygen accidentally present. It is assumed that at the moment of issue, the water is charged with 20.6 inches of nitrogen, and 15.66 inches of carbonic acid." (Dr. Lyon Playfair, in Dr. Wm. Henry Robertson's 'Handbook to the Peak of Derbyshire,' London, 1854, Bradbury & Evans.)

Owing to the quantity of calcareous matter, the water is hard. It sparkles a little when first received at the fount. It is exceedingly clear, and does not become turbid by long exposure to the air. Over the bath a stratum of vapour hovers, which is more or less dense according to the state of the weather and the degree of attention paid to the ventilation of the apartment. The chalybeate spring contains about half a grain of carbonate of iron in each gallon, and is a soft water.

The waters issuing from the warm spring are employed both internally and externally. A course of the water internally is generally taken at the same time as the baths are used; but in some habits of body the one mode only is admissible. Persons of the sanguineous temperament, especially if plethoric, can rarely take the waters internally, without at least previously undergoing some preparatory treatment,—either venesection, cupping, or the use of purgative medicines. During all acute inflammatory diseases they must be avoided; and though very beneficial to persons subject to gout and rheumatism, the waters must not be employed either when an attack of the disease is approaching, or while much pain of the joints remains when the disease is receding. Persons in whom the digestive organs are feeble, either naturally or from the effects of what is termed *good living*, derive, in general, much benefit from the internal use of these waters. In most cases they should be taken early in the morning, after the bath, if these two modes be employed simultaneously. The quantity to be used should not at first exceed half a pint, taken in two equal portions, a quarter of an hour (during which the invalid will walk along the terrace when practicable) being allowed to intervene between the two glasses. About noon the same quantity should be again taken, observing similar rules. Some patients are however obliged to restrict themselves to its use during the forenoon, omitting the morning dose. No one should exceed a pint and a half in the course of each day.

The chalybeate water is sometimes used at the same time, and it is said that a mixture of the two forms a purgative draught. Upon the propriety of using the chalybeate at any period during his stay, the invalid must consult his medical adviser on the spot. It ought never to be used as a common drink, more particularly by persons of a plethoric habit of body.

The warm baths may be employed even by the most delicate persons, provided bathing in any form be proper. At first the stay in the bath should not exceed one minute, as the plunge is the most beneficial part of the process. The time may be gradually extended, but should never exceed fifteen minutes. Where a general bath cannot be borne by gouty or rheumatic patients, pumping the water upon the affected joints is frequently highly efficacious in reducing the swelling and

restoring flexibility. During the use of the baths no mercurial medicines of any kind should be taken, unless under the direction of a competent medical adviser on the spot.

(Farey's *Derbyshire*; Gairdner on *Mineral Springs*; Denman, Saunders, Scudamore.)

BYLAW. Bylaws are the private regulations of a society or corporation, agreed upon by the major part of its members, for purposes of self-government, or for more conveniently carrying into effect the object of its institution.

It is not every voluntary association to which the law of England gives the power of binding dissentient members by the enactments of the majority. Immemorial custom or prescription, or legal incorporation by the crown, or by or under the provisions of a statute, is necessary to confer this power of local or private legislation; and even in those cases the Courts of law exercise the right of discussing the validity or policy of the bylaw, and of establishing its legality or declaring it to be void. In order to stand this test it must be reasonable and agreeable to the general policy of the law of England, and must not attempt to bind strangers unconnected with the society, or to impose a pecuniary charge without a fair equivalent, or to create a monopoly, or to subject the freedom of trade to undue restraint. The general object of a bylaw is thus rather to regulate existing rights than to introduce new ones or to extinguish or restrain the old. And where authority to make such regulations is conferred by charter or statute, the powers to do so must be strictly followed in making it, or the bylaw itself will be void.

The power of making bylaws is not absolutely confined to corporate bodies. It is in some instances lawfully exercised by a class of persons having no strict corporate character. Thus the tenants of a manor, the jury of a court-leet, the inns of court, the inhabitants of a town, or other district, sometimes enjoy a limited legislative power of this kind, by special custom or common usage. But in general the power is exercised only by incorporated bodies, and in such bodies the power is inherent of common right without any specific provision for that purpose in the charter of their incorporation. The expediency of this power is so obvious that we cannot be surprised at meeting with proofs of its existence in all countries and at a very early date. The Roman code recognised a right among the confraternity of its corporations to bind one another by similar engagements, as long as they were not at variance with the public law ('Dig.' lib. xlvii. tit. 22), and professes to borrow this provision from the still more ancient code of Solon.

Our own term *bylaw* is of Saxon origin, and is formed by prefixing to the word *law* another word *by* or *bye*, which means *house* or *town*. Hence its primary import is *town-law*, and in this form and with this meaning it is said to be found among the ancient Goths, the Swedes, the Danes, and other nations of Teutonic descent. (Cowel, voc. 'Bilaws'; Spelman on 'Feuds,' chap. ii., and the Glossaries under the head 'Bilago,' or 'Bellago'.)

The *birlaws* and *birlaw courts* of Scotland, mentioned by some of the jurists of that country, are said to present some analogies to our bylaws, and may perhaps be referred to the same origin.

The statutes regulating municipal corporations give to the town councils a power of making bylaws for the good rule and government of the boroughs, and for the suppression of various nuisances; and of enforcing the observance of them by fines limited to 5*l*. The local boards of health, the trustees of turnpike-roads in public matters, railway, canal, and dock companies within their own limits, have also limited powers of making bylaws enforceable by penalties. Some joint-stock companies possess analogous authority for the proper carrying on their own business, and the regulation of their own affairs.

BYSSUS (βύσσος). It has been a subject of some dispute whether the byssus of the ancients was cotton or linen: but recent investigations have determined that it is linen, and not cotton; at least so far as the term has been applied by Greek and Roman writers to mummy-cloth. Herodotus states, that the Egyptians wrapped their dead in the cloth of the byssus; and it has been shown by microscopic observations, that every specimen of mummy-cloth yet examined is made of linen fibre. The name byssus came probably from the Phœnicians, and may be derived from בִּיץ butz. (Buxtorf's 'Lexicon'.) It is possible that writers later than the time of Herodotus may sometimes have applied the term indifferently either to cotton or linen cloth. Cotton was known in the time of Herodotus (B.C. 484—408), who calls it tree-wool (ἐπιγονάριον ἀπὸ ξύλου): but there is no evidence to prove that it was then cultivated in Egypt, or in any other country except India; or that it was in common use in Egypt. His remarks, so far as they go, seem to imply that the commodity was a rarity. ('Library of Entertaining Knowledge'; 'Egyptian Antiquities,' cap. v., vol. ii., part. i.)

BYZANTINE ARCHITECTURE is that style of ecclesiastical architecture which originated in Byzantium (Constantinople), and was employed throughout the middle ages by the architects of the Greek church. Before the separation of the Eastern from the Western empire, architecture had fallen into a very debased condition. But in Roman architecture, even in its lowest state of declension, there existed the germs of new and noble forms. As was said under **ARCHITECTURE**, all true architecture has been the result of a modification or adaptation of some previous system to present circumstances and requirements. When, therefore, the growth of the Christian Church called for build-

ings adapted to its ritual, and corresponding to the dignity and wealth of the worshippers, the early ecclesiastical architects turned to the architecture of Rome, the only architecture with which they were acquainted, and found the guidance they sought. Their earlier works were of necessity to a great extent imitative; but as they acquired mastery over their art, and came to understand more exactly what was required, they applied their examples with more and more freedom, until they had, probably almost unconsciously, invented or rather developed a new style of architecture. In the Western empire, Roman architecture became in the hands of the ecclesiastical architects what is now known as the Romanesque. This, as it spread through Italy, Germany, France, and England, was variously modified into what we are sometimes apt to speak of as distinct styles under the names of the Lombardic, Norman, &c.; its ultimate development being into the Gothic. In the Eastern empire, on the other hand, Roman architecture became what we have now to notice as the Byzantine type, which in its turn influenced, more or less, all subsequent Oriental architecture, as well as that of the Slavonic races, and, by way of Venice and Marseille, extended its branches into Italy, the South of France, and even Germany.

The origin of Byzantine architecture dates from the foundation of Constantinople by Constantine in A.D. 328. Nothing was omitted which the imperial power as well as the imperial wealth could accomplish, in order to impart magnificence to the city which was not only to serve as the metropolis of the East, but to bear the emperor's own name, and to convey to posterity a due impression of his genius and his power. The ablest architects and the most skilful artificers were summoned from the capital of the West to raise the capital of the East; and the cities of Greece and Asia were despoiled of their most valuable ornaments to contribute to its splendour. Gibbon has collected from a wide range of authorities a striking account of the enthusiasm and the rapacity of the emperor, and the splendour of the new city. ('Decline and Fall,' chap. xvii.) It is not necessary to follow him in the enumeration of the public halls, theatres, baths, porticoes, aqueducts, palaces, temples, and churches which were erected. Probably constructed hastily, and with a view to gorgeousness of effect, they possessed little originality of character, or even correctness of imitation. We are told, indeed, that "the impatience of Constantine soon discovered that, in the decline of the arts, the skill as well as number of his architects bore a very unequal proportion to the greatness of his designs." And that in consequence, "the magistrates of the most distant provinces were directed to institute schools, to appoint professors, and by the hopes of rewards and privileges, to engage in the study and practice of architecture a sufficient number of ingenious youths, who had received a liberal education." (Gibbon.) In this step we perhaps may discover the true foundation of the new style. Young men thus impressed, as it were, from all parts, and trained with a view to meet an urgent requirement, would be far more likely to regard their art with a practical eye, to consider how they could best adapt the edifices they had to construct, so as to fulfil the purposes for which they were to be erected, and employ the materials at hand, rather than to encumber their minds with questions of precedence and academic propriety. And hence, in the churches the character and requirements of the ritual, and the arrangements called for by climate and the habits of the worshippers, would be studiously considered; and thus a style would be gradually formed like that actually found to exist—traceable back to the debased Roman of the 3rd century, but impregnated with a decided Orientalism of thought and well adapted, as it is generally admitted to be, to the locality in which it originated, and to the service of the Greek Church.

Of this First Period of Byzantine architecture which is considered to extend over a couple of centuries, from about 330 to 500, there are, however, few, if any, examples remaining which enable us to trace the actual progress of the style. The church of St. Johannes, constructed in the middle of the 5th century, is perhaps the oldest remaining in Constantinople. It shows that the Roman influence was still dominant. It is basilican in form [BASILICA], unlike the true Byzantine church, which always is, or approximates to, that of the Greek cross. The columns are imitations of a classic type, the order being Corinthian. Ample illustrations of this church will be found in the magnificent work of Herr Salzenberg, cited below. Other examples of this period are the church of St. John at Salonica, that of the Holy Sepulchre at Jerusalem, &c. As far as present investigations have shown, it may however be said that during this, its First Period, Byzantine architecture, with some local peculiarities, is essentially the same as the contemporary Romanesque.

The Second Period is, however, that of Byzantine architecture proper. It dates from the time of Justinian, who may indeed be regarded as its founder. The grand characteristic of the true Byzantine style is its use of domes and cupolas. A Byzantine or Greek church, in plan a Greek cross, consists of a great central square covered by a dome, other parts being covered by semi-domes or cupolas; west of the dome is a spacious extension called the narthex, while the east end terminates in a triple apsis. The interior consists of five divisions: 1, the *narthex* (western porch or vestibule), which is set apart for catechumens—the ground-floor being devoted to males, the gallery to females; 2, the *nave*, separated from the narthex by a screen, and from (3) the *choir*, usually by a low wooden barrier; 4, the *bema*, or

sanctuary; and 5, the *apsis* (usually tripartite), which forms the holiest place, and is shut off from the bema by a wooden screen which reaches to the roof or ceiling: this screen is called the *Iconostasis* (Εἰκόναστας) from the sacred pictures which are on its panels. Three doors in this screen lead from the bema to the apsis.

Externally Byzantine churches of this period exhibit little splendour. Columns are beginning to be a subservient and merely decorative feature. The capitals are little more than square blocks, tapering downwards, the ornament being either basket-work or foliage, and like the ornament generally in very low relief—the ground of the ornament being sunk below the general surface: sometimes disconnected volutes occur in their proper places, but occasionally at the bottom of the capitals. The arches are semi-circular. The domes and semi-domes, or cupolas, rise from nearly flat roofs. The great pillars which bear the central dome, are square; and pendentives [DOME], first adopted in the church of Sta. Sophia, are employed with great skill. The domes are for the most part pierced at their bases with numerous windows; the great dome of Sta. Sophia has 40. Coloured marbles are used for the shafts and other internal features, and rich mosaics are freely employed: the architects evidently trusting largely to polychromatic decoration for their general effect.

The most important example of this period, the typical example indeed of pure Byzantine architecture, is the church of Sta. Sophia at Constantinople (now, as is well-known, a Mohammedan mosque, the Aya Sofia), built in 532, by the emperor Justinian. Gibbon's account of its erection and of the building itself is so admirable that, though the passage be long, it will be more satisfactory to quote it than to give a dry technical description. He says:—

"The principal church, which was dedicated by the founder of Constantinople to Saint Sophia, or the Eternal Wisdom, had been twice destroyed by fire; after the exile of John Chrysostom, and during the *nika* of the blue and green factions. (January, 532.) But at the end of forty days a new temple was strenuously undertaken by the piety of Justinian. . . . Anthemius formed the design, and his genius directed the hands of ten thousand workmen, whose payment in pieces of fine silver was never delayed beyond the evening. The emperor himself, clad in a linen tunic, surveyed each day their rapid progress, and encouraged their diligence by his familiarity, his zeal, and his rewards. The new cathedral of St. Sophia was consecrated by the patriarch, five years eleven months and ten days from the first foundation; and in the midst of the solemn festival, Justinian exclaimed with devout vanity, 'Glory be to God, who hath thought me worthy to accomplish so great a work; I have vanquished thee, O Solomon!' But the pride of the Roman Solomon, before twenty years had elapsed, was humbled by an earthquake, which overthrew the eastern part of the dome. Its splendour was again restored by the perseverance of the same prince; and in the thirty-sixth year of his reign, Justinian celebrated the second dedication of a temple, which remains, after twelve centuries, a stately monument of his fame. . . . The dome of St. Sophia, illuminated by four-and-twenty [40] windows, is formed with so small a curve that the depth is equal only to one-sixth of its diameter; the measure of that diameter is 115 feet, and the lofty centre, where a crescent has supplanted the cross, rises to the perpendicular height of 180 feet above the pavement. The circle which encompasses the dome, lightly reposes on four strong arches, and their weight is firmly supported by four massy piles [piers], whose strength is assisted on the northern and southern sides by four columns of Egyptian granite. A Greek cross, inscribed in a quadrangle, represents the form of the edifice; the exact breadth is 243 feet, and 269 may be assigned for the extreme length from the sanctuary in the east to the nine western doors which open into the vestibule, and thence into the *narthex*, or exterior portico. . . . Beyond the northern and southern piles, a balustrade, terminated on either side by the thrones of the emperor and the patriarch, divided the nave from the choir; and the space [bema] as far as the steps of the altar, was occupied by the clergy and singers. The altar itself, a name which insensibly became familiar to Christian ears, was placed in the eastern recess [the apsis] artificially built in the form of a demicylinder; and this sanctuary communicated by several doors with the sacristy, the vestry, the baptistery, and the contiguous buildings, subservient either to the pomp of worship or the private use of the ecclesiastical ministers. The memory of past calamities inspired Justinian with a wise resolution, that no wood, except for the doors, should be admitted into the new edifice; and the choice of the materials was applied to the strength, the lightness, or the splendour of the respective parts. The solid piles [piers] which sustained the cupola were composed of huge blocks of freestone, hewn into squares and triangles, fortified by circles of iron, and firmly cemented by the infusion of lead and quicklime; but the weight of the cupola was diminished by the levity of its substance, which consists either of pumice-stone that floats in the water, or of bricks from the Isle of Rhodes five times less ponderous than the ordinary sort. The whole frame of the edifice was constructed of brick; but those base materials were concealed by a crust of marble; and the inside of St. Sophia, the cupola, the two larger and the six smaller semi-domes, the walls, the hundred columns, and the pavement delight even the eyes of barbarians with a rich and variegated picture. A poet, who beheld the primitive lustre of St. Sophia, enumerates the colours, the shades, and the spots of ten or

twelve marbles, jaspers, and porphyries, which nature had profusely diversified, and which were blended and contrasted, as it were, by a skilful painter. The triumph of Christ was adorned with the last spoils of paganism; but the greater part of these costly stones was extracted from the quarries of Asia Minor, the isles and continent of Greece, Egypt, Africa, and Gaul. Eight columns of porphyry, which Aurelian had placed in the temple of the Sun, were offered by the piety of a Roman matron; eight others of green marble were presented by the ambitious zeal of the magistrates of Ephesus: both are admirable by their size and beauty, but every order of architecture disclaims their fantastic capitals. A variety of ornaments and figures was curiously expressed in Mosaic; and the images of Christ, of the Virgin, of saints, and of angels, which have been defaced by Turkish fanaticism, were dangerously exposed to the superstition of the Greeks. According to the sanctity of each object, the precious metals were distributed in thin leaves or in solid masses. The balustrade of the choir, the capitals of the pillars, the ornaments of the doors and galleries, were of gilt bronze; the spectator was dazzled by the glittering aspect of the cupola; the sanctuary contained 40,000 pound weight of silver; and the holy vases and vestments of the altar were of the purest gold, enriched with inestimable gems. Before the structure of the church had risen two cubits above the ground, 45,200 pounds were already consumed, and the whole expense amounted to 320,000 pounds: each reader, according to the measure of his belief, may estimate their value either in gold or silver, but the sum of one million pounds sterling is the result of the lowest computation." ('Decline and Fall,' ch. xi.)

More strictly architectural descriptions of this remarkable building, in its present as well as in its ancient state, will be found in the works referred to below, especially those of Fossati and Salzenberg: the former had the rare advantage of studying it quite unrestrained, he having been employed by the Sultan (or rather the minister Reschid Pacha) to repair and in part restore the building. Salzenberg's work is one of the most beautiful architectural monographs yet published. As will have been noticed, Gibbon, with all his warmth of description, speaks disparagingly of Sta. Sophia as a work of art. Of late years a different opinion has been gaining ground; M. Fossati, who has spent so much time in its study, may easily be regarded as enthusiastic when he expatiates on the "majesty of the *ensemble* and the perfection of the details" of "this grand architectural master-piece," and asserts that he "knows not any other monument in the world the proportions of which are so vast and so majestic;" but it is otherwise when we find the interior of Sta. Sophia held forth by a high authority in our own country as the finest domical interior of ancient or modern times, both for appropriateness and beauty; while, it is added, "if we regard it with a view to the purposes of Protestant worship, it affords an infinitely better model for imitation than anything our own mediæval architects ever produced." (Fergusson, 'Handbook of Arch.,' ii. 951.) Without going as far as this, there can be no doubt that a careful study of Byzantine interiors, with those of our own Wren, would have been far more beneficial to Protestant church architecture than the unreasoning imitation of Gothic forms which has so generally prevailed of late years, even whilst retaining Gothic as the basis of our ecclesiastical style.

The church of SS. Sergios and Bacchos, or as it is commonly called the lesser Sta. Sophia, is another very admirable, but smaller and less gorgeous, example of this period yet remaining at Constantinople; its central dome is 47 feet in diameter. St. Irene (now used as a museum for antique arms) is still smaller, but has some interesting features. Salzenberg gives illustrations of both these churches.

The Third Period extends from about 800 to 1200, when Byzantine architecture proper may be considered to have expired: in the period between the taking of Constantinople by the Venetians (1204) and its final conquest by the Turks (1453), such art as existed having become corrupted by the admixture of various foreign and incongruous elements.

In this Third Period, while the interiors are still adorned in as costly and splendid a manner as possible, more ornament is expended upon the exterior of the building than in the preceding, and more Orientalism

of character is imparted to the general design. The domes and semi-domes are much smaller, and are raised on cylinders which reach to the height of the windows, so that the curved part is less than a hemisphere. Coloured shafts and flat surface decorations are much employed on the outside of the buildings. All the churches of this period in Constantinople are much inferior in size, as well as in richness, to Sta. Sophia. The finest remaining is that of Sta. Theotokos (9th century), which is, however, only 45 feet by 37 in the interior (exclusive of the narthex), with a central dome only 14 feet in diameter, but having three other domes over the narthex of scarcely inferior dimensions. The church of S. Pantokrator, founded in the beginning of the 12th century, is a kind of triple church, the central one having, as is believed, been intended as the sepulchre of the founder.

But the noblest example of the Byzantine architecture of this period is the church of St. Mark at Venice, which, begun in 977, was not finally completed till the latter part of the 12th century. Venice at this time belonged rather to the Eastern than to the Western empire, and the architects of the new church were brought from Greece, as were later the workers in mosaic; but whether the design was from Constantinople or Alexandria, is by no means certain. The plan of the church is a Greek cross, which is crowned with a central and four other domes, of equal diameters. The interior is 205 feet long; the transepts are 164 feet; but the external dimensions are 264 feet by 215. It is built of brick, but veneered on the exterior with marble. Much has been added to the church since its erection, and many of the original features have been concealed by subsequent alterations. Much of the ornamentation of the western front, and the peculiar cupola-like terminations which now surmount the domes, are of considerably later date, and belong to quite a different architectural style. Still the work retains the true Byzantine character, especially in the interior, which is unique in the "truly Byzantine profusion of gold mosaics which cover every part of the walls above the height of the capitals of the columns, and are spread over every part of the vaults and domes; being, in fact, the real and essential decoration of the church, to which the architecture is entirely subordinate. Externally, its great beauty consists in the profusion of marble columns, which surround and fill all the front and lateral porches. Like those in the interior, they have no constructive office to fulfil, but they are in themselves rich and beautiful, and are most picturesquely disposed." (Fergusson.)

The church of St. Antony at Padua bears a considerable resemblance to St. Mark's, but has a central dome, and five other domes over the nave, transepts, and choir, and two slender towers; it is, however, not so purely Byzantine in character, and much less graceful in form. A much closer imitation, though wanting the splendour of St. Mark's, is the church of St. Front at Périgueux, which M. de Verneilh assigns to the beginning of the 11th century. Another very important church of this period, usually termed Byzantine, is the cathedral of Pisa, which, with its connected baptistery, campanile, and campo santo, forms one of the most striking architectural groups in Europe. But though it has much that is Byzantine in character, it has so much that is Romanesque, that it cannot perhaps be fairly classed as Byzantine. Its architect was, however, a Greek, Buschetto of Dulichio, who erected it in the beginning of the 11th century.

For other true Byzantine churches in Greece, Asia Minor, Italy, France, &c., and for fuller particulars respecting the style itself, we must refer the reader to the works cited below, only remarking that, as in the instance of Pisa, it is now generally felt that some of the authors who have specially written on the subject have been led by their enthusiasm to extend Byzantine influence much farther than a cooler and more searching investigation warrants.

(A. Couchaud, *Choix d'Eglises Byzantines en Grèce*, fol. Paris, 1842; G. Fossati, *Aya Sofia Constantinople, as recently restored by order of H. M. the Sultan Abdul Medjid*, fol. London, 1852; W. Salzenberg, *Alt-Christliche Baudenkmale von Constantinopel*, fol. Berlin, 1854; Neale, *History of the Holy Eastern Church*, London, 1850; F. de Verneilh, *L'Architecture Byzantine en France*, Paris, 1851; De Caumont, *Cours*, vol. iv.; Hope, *Hist. of Architecture*; Fergusson, *Handbook of Architecture*; &c.)

C

C. This letter is derived from the Latin alphabet, in which it first appears. But even in that alphabet it originally possessed the power of *g*, as pronounced in *goose*. Thus the Roman proper names *Caius* and *Cneius*, which retained this sound, are correctly represented in the Greek character by *Gaios* and *Gnaios*; and the Duilian inscription presents *macestratus*, *leciones*, *pucnandod*, *ecfociont*, in the place of the modern forms, *magistratus*, *legiones*, *pugnando*, *ecfugiunt*. Indeed the poet Ausonius expressly states that *C* once performed the duty of *G*: *Gammæ vice functa prius C*. (See also Festus, *vv. Prodigia, Orcum*.) This medial pronunciation corresponds with the power of the letters which occupy the third place in the Greek and Hebrew alphabets, *gamma* and *gimel*; and the identity of the letters is confirmed by the similarity of the forms. [ALPHABET.]

The letter *c* in English is pronounced as *s* before *i*, *e*, and as *k* before *a*, *o*, *u*. This variety in the power of the letter seems difficult to account for; but it may be observed that *i*, *e*, belong to one end of the vowel series, *a*, *o*, *u*, to the other [ALPHABET]; and it is further to be noticed that the vowels *i* and *e*, when they precede vowels, have a power approaching to that of *y* in *youth*, and that if in addition to this, *c* or *g* precede, there often results a sound like that at the beginning of the words *church* and *John*, and this sound of *ch* is not very different from a sibilant. The vowels *i* and *e* produce a similar sound when preceded by *d* or *t*, and followed as before by a vowel. Thus from *ratio* the Italians have obtained *ragione*; and from *radio*, *raggio*; from *Diana* the rustics of Italy made *Jana*. These considerations are perhaps supported by the employment of the little mark called *cedilla* in the French language, which is used to denote that *c* is to be pronounced as *s* even before the other vowels, as *ça*; for the mark appears to have been originally an *i*. The connexion of the sounds *k* and *s* will be again spoken of.

The letter *c*, when pronounced as in *cat*, belongs to the order of guttural or throat letters, and among these it is distinguished by that character which grammarians have denoted by the Latin word *tenuis*, "thin." The correct distinction of the letters called *tenuis*, as opposed to those which bear the name of *medialis*, is perhaps this, that in the pronunciation of the *tenuis* *p*, *k*, *t*, the organs employed in articulation have only a small portion of their surfaces brought into contact, and that but for a short time; while in the articulation of *b*, *g*, *d*, the surface in contact is more extensive and the effort less rapid.

The letter *c* is liable to the following interchanges: 1. In the derivation of French words from the Latin, *c* before *a* is changed into *cha* or *che*; ex., the Lat. *camera*, a vaulted chamber, *castus*, chaste, &c., *carus*, dear, *cadere*, to fall, *casa*, cottage, appear in French under the forms, *chambre*, *chaste*, &c., *cher*, *cheoir*, *chez*, &c. In this way the English language has derived *channel*, *chivalry*, *charnel*, *chattels*, through the French from the Latin *canalis*, *caballus*, *caro* (*carnis*), *capitalia*; and at the same time possesses the words *canal*, *cavalry*, or *cavalcade*, *carnival*, *cattle*, derived from the same roots, but by a different route. In the *patois* prevailing in the N.E. of France, the sound of the *k* still remains in these words, *chemin* being pronounced *kemin*, *chat* as *cat*.

2. The change of *c* into *ch* prepares us in some measure for that of *c* into *s*, as Lat. *facimus*, we do, Fr. *faisons*; Lat. *placere*, *licere*, Fr. *plaisir*, *loisir*, Eng. *pleasure*, *leisure*. This interchange of *c* and *s* is strongly exemplified in the comparison of the Western languages of Europe with those lying towards the East. Thus we have in Latin, *canis*, dog; *conca*, shell; *centum*, hundred; *decem*, ten; *cannabis*, hemp; in Greek, *kuon* (κυν), *konche* (κογχη), *hekaton* (ἑκατον), *deka* (δεκα), *kannabis* (κανναβις); in Sanskrit, *savan*, *sanca*, *sata*, *dasan*, *sana*; and in Russian, the forms for *calamus*, *cor*, *centum*, *canis*, are *soloma*, *verdise*, *sott*, *sobaka*. It should be stated, however, that the *s* in the Sanskrit alphabet, which is thus convertible with the *k* of the West, is a letter of a peculiar character, and is marked by a distinct symbol. Even Herodotus has observed (ix. 20) that the commander of the Persian cavalry, Masistios, was called by the Greeks Makistios, and the same interchange may occasionally be seen in the Teutonic languages, as in the German *faust* and *fechten*, Eng. *fist* and *fight*, words as certainly related as the Latin *pugnare* and *pugnis*. The pronunciation of the Latin *c* as an *s* in such words as Cicero, Caesar, is proved to be incorrect by the Greek equivalents *Kikeron* (Κικερων), *Kaisar* (Καισαρ), and no less so by the co-existence of such forms as *acer*, *acris*; and it would be trifling to defend the pronunciation by the accidental identity in form of the Roman *c* and one of the many symbols for the Greek sigma. [ALPHABET.]

3. *C* initial of the Latin language corresponds to *h* in the German. Compare *collum*, *hals*, neck; *celare*, *hehlen*, hide; *cutis*, *haut*, hide; *cannabis*, *hanf*, hemp; *canis*, *hund*, hound; *cornu*, *horn*, horn; *calamus*, *halm*, stalk; *caput*, *haupt*, head; *cor* (*cord*) *herz*, heart; *crates*, *horte*, hurdle. Traces of the same change are visible within the Latin itself, as *traho*, *traxi* (*trac-si*); *veho*, *vexi* (*vec-si*); and the town of Apulia,

called by Strabo Kerdonia, is called by Roman writers Herdonia. So the Greeks had *ossos* (οσσος), an eye, while the Romans preferred *oculus*.

4. *C* is convertible with *v* and *w*. This may be seen in the related forms *Dacus*, *Darus*; *focus*, *foveo*; *nix*, *nivis*; *conniveo*, *connixi*; *lacus*, *lavo*; *vivo*, *vixi*; *struo*, *struxi*. Thus too the English * *quick* (the original meaning of which is seen in the phrases "the quick and the dead," "the quick of the nail,") is identical with the Latin *vivus*; and we have another remarkable example in the derivation of our words *eleven* and *twelve* from the Latin *undecim*, *duodecim*. [See L.]

5. *C* into *g*. The change already mentioned of the power of the Roman symbol *c* is a sufficient proof of this. We may add *eager*, *meagre*, derived through the French *aigre*, *maigre*, from the Latin *acer*, *macer*. The old meaning of *eager* in Shakspeare is sharp, sour, as *eager milk*; and indeed the word appears again in *vinegar*, *vinaigre*. So too *aveugle*, blind, must have come from a Latin word, *aboculus*. The same change appears in the Teutonic. To the Latin *oculus* corresponds the German *auge*; to *duc-o*, *zog* and *zug*; while the Latin *lacr-uma*, or Greek *dakr-yon*, has in Gothic the form *tagr*, a tear.

6. The interchange of *c* with *p* is most remarkable in the Greek and Latin languages, the former commonly preferring the labial. Gr. *pepo*, Lat. *coquo*, cook; Gr. *leipo*, Lat. *linquo*, leave; Gr. *pipto* (or rather *pi-pet-o*), Lat. *cad-o*, fall, &c. The same interchange appears within Italy itself; the pigeon in Rome was called *columba*, the pigeon out of Rome, that is the wild pigeon, was called *palumba*; so *proximus*, nearest, has supplanted *prosimus*, from *prope*, near. The Latin word *quicquid* was pronounced by an Oscan as *pitpit*, and Augustus, we are told by Suetonius (Octav. 88), cashiered an officer for his ignorance in spelling *ipse* with an *a*.† This convertibility of the *tenuis* extends to the letter *t*. Thus we find *scapula* and *spatula* both conveying the notion of a blade. The Greek *tetartos*, fourth, *tis*, who, *te*, and, appear in Latin as *quartus*, *quis*, *que*. The old name of the rock of Gibraltar assumes the various forms, *Calpe*, *Carpe*, *Carte*, *Tarte*. And in English we have *nut*, from Lat. *nux* (*cs*); and, on the other hand, *cork* from *cort-ex*.

7. Latin words beginning with *cu* have often lost the guttural. Thus *ubi* occupies the place of *cubi*, an old dative of the relative (compare *sicubi*, *alicubi*, &c.); *uter* of *cuter* (compare the Greek *koteros*), *umquam* of *cumquam* (compare together *quis*, *cum*, *quisquam*). This variety appears in our own tongue, where *which*, formerly *whilk*, was once written *quwhilk*.

8. *C* often disappears before *l* and *n*. This naturally arises from the difficulty of pronunciation, as in *knee*, Lat. *genu*; *know*, Lat. *gno-sco*; thus from the old Frank name Clodovick are derived Clovis, Louis, Ludovicus, Ludwig, Lovick.

9. In the derivation of Italian and French words from the Latin, *c* disappears before a *t*, the preceding vowel being commonly strengthened, as Lat. *dictus*, said, It. *ditto*, Fr. *dit*; Lat. *coctus*, cooked, It. *cotto* (whence *terra cotta*), Fr. *cuit* (whence *bis-cuit*, twice baked). It also disappears at times before an *r*, as in Lat. *sacramentum*, oath, Fr. *serment*; Lat. *lacrima*, a tear, Fr. *larme*. Lastly, the same fate awaits it when flanked on either side by vowels; compare the Latin *locus*, *jocus*, *focus*, *paucum*, *vices*, *apicula*, *corbicula*, *oculus*, *nocere*, &c., with the French *lieu*, *jeu*, *feu*, *peu*, *fois*, *abeille*, *corbeille*, *œil*, *nuire*, &c.

C is the Latin symbol for a hundred. Whether it is so used as being the first letter of *centum*, a hundred, may be doubted. [NUMERALS.]

CABAL is often applied to a set of persons, too insignificant in point of number to form a party, who endeavour to effect their purposes by underhand means. The ministers of Charles II., Clifford, Ashley, Buckingham, Arlington, and Lauderdale, the initials of whose names happen to form the word cabal, were appropriately called the "Cabal Ministry." The word "cabal" appears to 'come from the French *cabale*, a term employed to express a number of persons acting in concert; and it is generally understood in a bad sense. (Richelet.) It was, however, used in our language a considerable time before the formation of the Cabal Ministry mentioned above.

CABBAGE. There are several species of the genus *Brassica*, or cabbage, which comprehends the turnip, the rape, the cole, and the common culinary cabbage, or *Brassica oleracea*. The innumerable varieties arise from difference of soil and cultivation; and as all the cabbage tribe form hybrids, new varieties are continually produced. This is effected by the bees, when different sorts are in flower at the same time. The pollen adheres to their body as they seek honey in the flowers, and being deposited on the pistils of other sorts, impregnates the germen. Hence only one variety of cabbage should be

* In some of the provinces of England 'wick' is used in the sense of quick. A thing that is alive is said to be 'wick.'

† In our own language we have *rock* (Fr. *roche*), from the Latin *rupes*, *scum* (Fr. *écume*) from *spuma*.

in flower at the same time in any garden or field, when we wish to keep the sort unadulterated; particularly if some sorts have expanded leaves, and others close heads. It is thus only that the excellent small miniature cabbage which grows on the stem of the Brussels' sprout, can be kept in perfection. The different sorts of cabbages most prized for the garden are chiefly divided into the close-hearting and the spreading. Of the first, the York and the Savoys are the most common; of the latter, the cole-worts and Scotch kale.

In order to have a regular succession of cabbages the seed should be sown at different times, from the beginning of spring to the autumn. The early sown will run to seed the same year; the later sown will increase more, produce larger and firmer heads, and will not go to seed till the next season. Some sorts, it is said, will continue to produce leaves for several years, if they are regularly taken off, and if the seed-stem is prevented from shooting by cutting it down as soon as it begins to appear. Thus a perennial cabbage-tree is produced, which yields abundance of food for sheep and cattle.

Cabbage plants are generally raised first in a seed-bed; when they are intended for early produce they are sown before winter, and protected by shelter or under glass frames. In this manner strong plants may be had early in spring, which planted out in April will produce fine cabbages by July or August. Those which are raised on a large scale are generally sown in March, and planted where they are to remain in June or July. When they have been pricked out from the seed-bed very young, and allowed to get to a good size in a piece of ground prepared for the purpose before being finally transplanted in the field, the success is more certain, and it will well repay the additional trouble. These come to perfection in autumn, and may be taken off the ground as they are wanted. Some kinds are so hardy that they will bear the severest frosts, and remain covered with snow for a considerable time without damage. Such are the green curly-leaved cabbages, or Scotch kale, which form no close head, but consist of spreading leaves. The great portion of nutritive matter in the leaves and stems of cabbages has made them an important object of cultivation wherever much cattle is kept, and where the land is favourable to their growth.

The cultivation of cabbages is the same in the field as in the garden, except that on a large scale less attention is paid to each plant, and the spade is superseded by the plough, and other instruments. A good and rather stiff loam is best adapted to cabbages. They require a considerable portion of manure if the land is not naturally rich, or if they are cultivated as a part of a regular rotation. There is no vegetable which produces so large a portion of food for cattle on the same space as the cabbage, provided the soil suits its growth. Though it impoverishes the ground, this should not prevent its being extensively cultivated, provided the nourishment it produces compensates for the additional manure required. The great advantage in the cultivation of the cabbage is, that a great portion of its substance is restored to the ground in all well-regulated farming establishments, in the shape of the dung and urine of the cattle fed upon them. It is asserted by experienced agriculturists that in this respect it is superior to the common turnip. The cultivation of the cabbage on a large scale is by no means so general on the soils well adapted to them as might be wished. This is probably owing to the trouble of transplanting, and the occasional failure of the plants in very dry weather. But the trouble and expense may be greatly diminished by attention and method. The plants may be raised in such abundance, by having a regular garden for the purpose, that they may be transplanted at various times, and the plants placed so thick as to allow for failures, whilst those which are superfluous may be hoed out. The cause of failure is generally in the careless manner of planting. Holes are usually made in the ground with some blunt instrument, the plants are put in without its being noticed whether the roots are doubled up or straight, whether the earth is pressed close to the roots, or vacancies are left between them and the soil, in which case they cannot take root properly.

If seed be sown in the garden in March, the plants will be ready to be dibbled in the field in May and June, and fit for consumption in autumn. It is well to prick out the young plants in lines before finally transplanting them in the field. In this last process the plough may be used. The ground having been well prepared, and being in good heart and tilth, a deep and narrow furrow should be opened. The plants having been carefully taken up without breaking the fibres of the root, the tops should be cut off to about six inches from the crown, women and children should then go along the furrow with baskets in which the plants are carefully laid, and place them, at the distance of eighteen inches or two feet from each other, against the earth which has been just turned over by the plough, so that the bottom of the roots shall lie along the newly made ridge, and the crown of the plant be on a level with the surface of the ground; a slight push will make it adhere to the fresh soil. If some rich mould is mixed with drainings of the dung-hill or ditch water to the consistency of soft mud, and the root of each plant is dipped in a pail of this mixture immediately before planting, the plants will seldom fail. The plough in returning covers all these roots with the earth of the next furrow; and a man follows and presses his foot obliquely against the furrow slice at the place where the head of the plant appears. The plough then takes two shallower and broader furrows, or leaves a

space of two feet between the last-made furrow, and forms another in which plants are again placed and covered up as before. The rows will thus be three feet wide. If the cabbages are of a large sort every alternate plant may afterwards be cut out, either as soon as they are fairly rooted, or when they have acquired a moderate size; in which case they will afford excellent food for cows and pigs, although not sufficient to stall cattle upon. The repeated use of the plough and horse-hoe between the rows is necessary for the growth of the cabbages, as well as highly useful to clean the land. By this mode of cultivation much labour is saved, the risk of the failure of the plants is greatly diminished, and if the ground has been well prepared and sufficiently manured, an astonishing weight of solid food for cattle is obtained. The best sort to plant in the field is the large drum-head cabbage. Should the ground be of great fertility, and at the same time compact, the large Strasburg cabbage, which grows to the weight of 60 lbs. and even 80 lbs., will produce an enormous weight of food. This cabbage is common in Germany.

When given to cattle or sheep, cabbages should be sliced in the same manner as turnips or beet-root. When milch cows are fed with them, all the decayed leaves should be carefully taken off and given to store cattle or pigs; for these are the chief cause of the bad taste which the milk and butter acquire from this food. [BUTTER.] For bullocks cabbages and oil-cake are excellent food, and increase their flesh rapidly. For sheep they should be sliced and given to them in troughs in the field where the cabbages grow, or on grass-land which requires to be manured. In England the sorts which have a close head are preferred; but where labour is abundant and forage scarce, as in France, the branching sorts are thought more profitable, because the leaves may be taken off repeatedly and will grow again. The thousand-headed cabbage, and the large cabbage of Poitou, as well as the tall cabbage, called *chou cavalier*, which grows with a stem six feet high, and gives large broad leaves without any close head, are greatly preferred in France to the sorts which bear close heads.

Cabbages are subject to a peculiar disease when repeatedly planted in the same ground: the bottom of the stem enlarges, and the plant becomes sickly. This disease is called *clubbing*, and is occasioned by an insect, which deposits its eggs in the substance of the stem where it joins the root: the organisation of the plant is deranged, and the cabbages never come to perfection. The only remedy for this disease is to change the cultivation, and for a time to plant no cabbages on the ground which produces clubbed plants, but to trench it up well, and expose it to the winter's frost in ridges: quick-lime should be put on it, but no manure; and other vegetables of a different class should be sown for two or three years. After this it may be considered as purified, and cabbages may safely be planted there again. In the fields, where cabbages do not return so frequently on the same ground, this disease is seldom found. The depredations of caterpillars and slugs are sometimes very great; the only means of prevention is to pick them off as soon as they appear: ducks and fowls in this case are excellent helps, the former especially, for clearing the ground of slugs.

In Germany there is an immense consumption of the large white cabbage in the form of the national mess, called *saur kraut*. This is prepared in the following manner: The cabbages are sliced thin by hand, or by a machine like a turnip-slicer, of the same kind as that by which French beans are sliced in Holland. [BEAN.] The bottom of a cask, of which the head has been taken out, is covered with salt, and a layer of thin-sliced cabbage six inches thick is laid over it; on this a quantity of salt is spread, and another layer of cabbage mixed with some juniper-berries and whole pepper; and thus salt and cabbage alternately until the cask is filled. A round board is then put into the cask so as nearly to fit it, and on this a heavy weight of stone or metal is laid. As the cabbage ferments and sinks, the cask is filled up with fresh salt and cabbage. After some time the expressed juice is poured off, some water with salt dissolved in it is poured over, and changed until it ceases to rise with a scum and fetid smell; the cabbage is then in a fit state to be kept. A cloth is laid over it, and over this the round board and weights. When any portion is taken out for use, a sufficient portion of brine is allowed to remain over the mass to exclude the air; and the cloth, board, and weights, are replaced as long as any cabbage remains. This *saur kraut*, when washed with soft water and stewed with bacon or salted meat, is a very wholesome dish, and much relished by those who have been early accustomed to it. In long voyages it has been found to be an admirable preservative against the sea-scurvy.

CA'BBALA. "The Jewish Cabbala," says Dr. Henry More, in the preface to his 'Conjectura Cabbalistica,' "is conceived to be a traditional doctrine or exposition of the Pentateuch, which Moses received from the mouth of God while he was on the mount with him. And this sense, or interpretation, of the law or Pentateuch, as it is a doctrine received by Moses first, and then from him by Joshua, and from Joshua by the seventy elders, and so on, was called *Cabbala* from קַבַּל, *kibbel*, to receive. But, as it was delivered as well as received, it was called *Masora*, which signifies a *Tradition*; though this latter more properly respects that critical and grammatical skill of the learned among the Jews, and therefore was profitable for the explaining the literal sense, as well as that more mysterious meaning of the text where it was

intended." In a wider sense, however, the Cabbala is used for the whole secret or esoteric philosophy of the Jewish doctors—a subject of great extent and intricacy, upon which voluminous works have been produced, both by Rabbinical and Christian writers. The most celebrated collection of the Rabbinical writings on the Cabbala is the work entitled 'Kabbala Denudata, seu Doctrina Hebræorum Transcendentalis,' &c., 3 vols. 4to. Sulzbach, 1676, and Frankfort, 1684. The editor of this work, which is a very rare book, the third volume in particular, is believed to be Christianus Knorrius à Rosenroth. Lists of the Rabbinical treatises on the Cabbala may be found in Wolf's 'Bibliotheca Hebræa,' and in the 'Bibliotheca Magna Rabbinica' of Bartoloccius and Imbonatus. Of the Christian writers on the Cabbala, the most famous are Picus of Mirandola, the younger Van Helmont, and his friend Dr. Henry More, the learned and eloquent English Platonist who, in his 'Conjectura Cabbalistica,' is earnest in its defence. Mosheim, on the contrary, says it was the doctrines of Greek paganism accommodated to the Jewish religion; that it was fruitful of errors, destructive of the very foundation of Judaism, that it produced many of the Gnostic heresies, and that it taught that the dominion of the supreme God was to be destroyed by the expected Messiah. There is a valuable article on the Cabbala by the Abbé Mallet, in the great French 'Encyclopédie.' A short popular account of this philosophy is given by the Marquis le Gendre in the 7th chapter of the third book of his 'Traité de l'Opinion.' The celebrated work of the Abbé de Villars, entitled 'Le Comte de Gabalis,' from which Pope avows that he took the machinery of sylphs and gnomes in his 'Rape of the Lock,' is a satire upon the mystical absurdities of the Jewish Cabbala. Bayle has noticed that the substance of this work is contained in the first two of ten letters attributed to the charlatan Joseph Francis Borri, and published at Geneva in 1681, under the title of his 'Chiave del Gabinetto' (Key of the Cabinet). [Art. 'Borri' note G.] Although the letters in question are dated at Copenhagen in 1666, there can be little doubt that they were stolen from the work of the Abbé de Villars, which was first printed in 1670.

CABIN, a term applied to the inclosed portions of a ship, in which her officers or passengers reside. A careful arrangement of cabins in Her Majesty's navy contributes much to the comfort and health of the occupants; while in the merchant service a judicious division of space in passenger ships finds special favour with the public. In large vessels of war the admiral's and captain's cabins extend across the ship near her stern, and they are usually divided into two, termed the *fore* and *after* cabins; the latter are considered more strictly private, while the former are used for dinner, for the reception of strangers, and other purposes. The cabins of the senior commissioned officers are generally upon the main deck; and each receives light and ventilation from a port, commonly having a heavy gun thereat; such cabins being at each side of the great "mess-cabin" or "ward-room," while the cabins of the others and "gun-room" officers are placed along each side of the lower or orlop-deck, near the water level, and are only partially lighted from a scuttle or stout glass bull's-eye in the ship's side. It is to the space between these cabins (called the "cockpit") that in battle the wounded are conveyed for medical help. The mess-cabin called the "gun-room" is usually on the deck below the ward-room.

In frigates the captain's cabin is on the main-deck, and the gun-room, or after part of the lower deck, is given to the officers; but in two-decked line-of-battle ships, the captain takes the cabin under the poop, and the officers the great cabin on the upper gun-deck. In three-deckers the ward-room is appropriated to the admiral, and the officers take the corresponding one on the middle gun-deck. The partitions by which all these cabins are enclosed are called *bulk-heads*, and are composed of light panelled frames, which are instantly removable when the decks are ordered to be cleared for action. In the merchant service totally different and greatly diversified arrangements exist. In large passenger-ships, a spacious and often grand saloon, fitted with taste and expense, offers to the voyager, in its luxurious couches, sofas, &c., the personal comforts of a drawing-room; while the gorgeous gildings and mouldings, and the various artifices and devices of the "decorator," are calculated to remind the traveller of the elegance of his home, even be that home a palace.

CABIRI (Καβίροι), ancient Pelasgian divinities, belonging to a system of elementary religion, which, in the later ages of Greece, was connected with the celebration of mysterious rites in the island of Samothrace. According to Strabo (p. 472), who quotes Stesimbrotus, they derived their name from Mount Cabeirus in Bercynthia. They were apparently the same as the Corybantes, &c. (Strabo, pp. 466, 472; Schol. on Aristoph. 'Pac.' 277), and their worship was most cultivated in Samothrace, Lemnos, Imbros, and certain towns of Troas. (Strabo, p. 473.) Their names were mystical, and are given by Mnaseas. (Schol. Apoll. Rh. i. 917.) Camilus, Cumilus or Cadmilus, was the son of Hephæstus and Cabeira, and his children were the three Cabeiri, from whom came the nymphs Cabeirades (Acusilaus, *ap.* Strab. p. 472). Camilus is stated to have been the same as Hermes, and the three Cabeiri mentioned by Mnaseas, Axieres, Axiocersa, and Axiocersus, are said to correspond to Ceres, Proserpine, and Pluto, respectively. It seems more probable, however, that Camilus represented the generative principle (Herod. ii. 51), and that the three Cabeiri were personifications of Love, the male and the female, the first part of each name being the epithet *ἄξιος* (worthy), which is very frequently applied to gods, and

the remaining parts, Eros, Kersos, and Kersa, having the significations which we have assigned to them. (κέρως, γάμος, Hesych.) Of the rites themselves very little is known. They appear to have been solemnised annually, and to have lasted nine days. Samothrace was the principal seat of the worship; but caberia, as the rites were called, appear to have been held at Samnos and Imbros, though some ancient writers assert that the rites in these places differed from those at Samothrace. All who took part in these underwent purification prior to admission, and they were strictly prohibited from divulging what they witnessed. The reader who is desirous of investigating this ancient religion may consult Creuzer's 'Symbolik' (ii. p. 318); Müller's 'Orchom.' (p. 450); Welcker's 'Trilogie'; Lobeck's 'Aglaoph.' (lib. iii. c. 6); Haupt's 'Religione Cabiriaca'; and Schelling's 'Treatise on the Samothracian Mysteries.' The images of the Cabiri were pigmy statues, of which there are specimens among the terra-cottas of the British Museum (Combe, no. 42). As the son of Vulcan, Cabeirus or Cadmilus is represented with a hammer in his hand. (Winckelmann, ii. p. 507.)

CABLE. [GROUND TACKLE.]

CABLE, CHAIN. [GROUND TACKLE.]

CABRIOLETS, PUBLIC. [STAGE CARRIAGES.]

CACAO, or, as it is commonly called, Cocoa, is the bruised seeds of the *Theobroma cacao*, a tree belonging to the natural order *Sterculiaceæ*. The seeds are oval, about as large as an olive, obtuse at each end, compressed, and covered with a violet or ash-gray skin, which encloses two irregularly-cut and plaited cotyledons, of a fatty nature, and of a brownish-black or violet colour. The properties of these seeds are owing to the presence of a fixed concrete oil and an agreeable aromatic principle. Simply bruised they constitute the cocoa of the shops; reduced to a paste, mixed with sugar, and flavoured with vanilla, they become chocolate. [CHOCOLATE.] They are imported from several of the West India islands, from Caracas, from Guayaquil, from Brazil, in all which places the tree grows wild, or is cultivated for the sake of its seeds. For a description of the tree and its mode of culture see THEOBROMA, in NAT. HIST. DIV.

The quantities of cacao imported into and consumed in this country in the years 1857 and 1858, were —

	Imported.	Consumed.*
1857	7,343,458 lbs.	3,762,594 lbs.
1858	7,256,520	2,777,194

CACHET, LETTRES DE, were letters proceeding from and signed by the kings of France, and countersigned by a secretary of state. They were called also "lettres closes, or "sealed letters," to distinguish them from the "lettres patentes" sealed by the great seal. Lettres de cachet were rarely employed to deprive men of their personal liberty before the 17th century. They were previously made use of occasionally as a means of delaying the course of justice; but during the reign of Louis XIV. they were obtained by any person who had sufficient influence with the king or his ministers, and persons were imprisoned for life, or for a long period, on the most frivolous pretexts, for the gratification of private pique or revenge. The terms of a lettre de cachet were as follows:—"M. le Marquis de Launay, je vous fais cette lettre pour vous dire de recevoir dans mon château de la Bastille le Sieur —, et de l'y retenir jusqu'à nouvel ordre de ma part. Sur ce, je prie Dieu qu'il vous ait, M. le Marquis de Launay, en sa sainte garde." These letters, giving power over personal liberty, were openly sold in the reign of Louis XV. by the mistress of one of the ministers. The lettres de cachet were also granted by the king for the purpose of shielding his favourites or their friends from the consequences of their crimes; and were thus as pernicious in their operation as the protection afforded by the Church to criminals in a former age. Their necessity was strongly maintained by the great families, as they were by them enabled to remove such of their connexions as had acted in a manner which was thought to bring discredit on the family. During the contentions of the Mirabeau family, fifty-nine lettres de cachet were issued on the demand of one or other of its members. The independent members of the parliaments and of the magistracy were proscribed and punished by means of these warrants. This monstrous evil was swept away at the Revolution, after Louis XVI. had in vain endeavoured to remedy it.

CACHOUTANNIC ACID. [TANNIC ACIDS.]

CACIQUE, a Mexican word which signifies "lord" or "master." It was generally adopted by Spanish writers to signify the chiefs, governors, or principal personages of those American tribes with whom the Spaniards became acquainted by their conquests in the New World. (Prescott, 'Conquest of Mexico;' and 'Conquest of Peru.')

CACODYL (C₂H₃As = Kd), an excessively poisonous organo-metallic body, containing arsenic. It is best prepared from its chloride in the following manner: Digest slips of zinc in chloride of cacodyl for three hours, in a glass bulb blown upon a glass tube previously filled with carbonic acid gas. The zinc dissolves without the evolution of any gas; when the residual white saline mass is treated with water, the chloride of zinc dissolves, and a heavy oily liquid separates, which is cacodyl, and is rendered pure by cautious distillation from a fresh portion of zinc.

Its properties are: It is a thin, transparent, colourless liquid, much resembling arseniuretted hydrogen in odour, and is so very

inflammable, that when poured into oxygen, chlorine, or the air, it takes fire; it boils at 338° ; when cooled to 21° it crystallises in large transparent square prisms. It is heavier than water, and being nearly insoluble in it, sinks when added to it. Alcohol and ether dissolve it. Its formula is $C_4H_6As = Kd$.

Oxide of Cacodyl.—Equal parts of arsenious acid and acetate of potash are to be accurately mixed and put into a glass or iron retort, to which a cooled receiver is adapted, with an apparatus to carry off the incondensable gaseous product, which is chiefly carbonic acid and hydride of methyl. When the heat has been long continued, some metallic arsenic and two liquids are found in the receiver: the lighter consists mostly of water, with acetic acid and acetone; and the heavier is impure oxide of cacodyl, or alcarsin, formerly called the *liquor of Cadet*.

The product is obtained in a pure state by repeated washing with water free from air, and redistillation from hydrate of potash in a retort containing hydrogen gas; this operation, on account of the poisonous nature of alcarsin, must be conducted with great care and special arrangements made for conveying away the fumes from the neighbourhood of the experimenter.

The properties of this substance are: It is a colourless liquid; its density is 1.462; its smell is extremely disagreeable, and the vapour affects the eyes and nose. Water dissolves little of it, but alcohol takes it up readily; it boils at about 248° , and solidifies, becoming a white crystalline mass, at 9° . By exposure to the air a dense white smoke is emitted, the alcarsin becomes hot, and afterwards burns spontaneously with a pale flame, producing arsenious acid, carbonic acid, and water. It is composed of 4 equivalents of carbon = 24, 6 equivalents of hydrogen = 6, 1 equivalent of arsenic = 75, 1 equivalent of oxygen = 8. Its formula is $C_4H_6AsO = KdO$.

Chloride of Cacodyl.—Mix a dilute alcoholic solution of oxide of cacodyl with one of corrosive sublimate, avoiding an excess of the latter; by their mutual action a colourless inodorous crystalline precipitate is obtained ($C_4H_6AsO, HgCl$); and when this is distilled with hydrochloric acid, there are formed water, chloride of mercury, and chloride of cacodyl, the latter coming over; this is subjected to the action of lime and chloride of calcium, and then distilled in a retort containing carbonic acid gas. The chloride of cacodyl thus produced is a colourless liquid; its odour is more disagreeable and its vapour more poisonous than that of the oxide of cacodyl; it does not fume when exposed to the air, but its vapour, which is colourless, is spontaneously inflammable in it. It is heavier than and insoluble in water; alcohol combines with it readily, but ether does not; its boiling-point is a little above 212° . Its formula is $KdCl$.

Iodide of Cacodyl (C_4H_6AsBr), and **Bromide of Cacodyl** (C_4H_6AsI), may be formed by treating the above hydrargyro-oxychloride of cacodyl with hydriodic, or with hydrobromic acid.

Cyanide of Cacodyl ($C_4H_6As, NC_2 = KdCy$) may be obtained by distilling oxide of cacodyl with hydrocyanic acid, or a strong solution of cyanide of mercury. The product crystallises in brilliant prisms. Fusing point 91° , boiling point 284° . Vapour density 4.63. This compound is even more deadly poisonous than the other compounds of cacodyl. A single grain diffused in vapour through the atmosphere of an ordinary apartment causes numbness of the hands and feet, giddiness, a buzzing noise in the ears and sometimes fainting; but usually these symptoms are of short duration after the poisoned air has been removed.

Sulphide of Cacodyl ($C_4H_6As, S = KdS$) is best obtained by distilling a mixture of sulphide of barium and chloride of cacodyl. It is a colourless transparent liquid, of an exceeding penetrating fetid odour. Its boiling point is 212° . It does not solidify at a temperature of -40° . Vapour density 7.72. It is insoluble in water, but miscible in all proportions with alcohol and ether.

Sulphocacodylic Acid ($C_4H_6AsS_3$), or tersulphide of cacodyl, is obtained in combination by precipitating metallic salts with sulphocacodylate of cacodyl, or bisulphide of cacodyl, a compound obtained by acting upon cacodylic acid with sulphuretted hydrogen.

Cacodylic Acid ($C_4H_6AsO_3 = KdO_3$). **Alcargen.**—When cacodyl or its oxide is left under water to the slow action of the air, they oxidise and become cacodylic acid; or it may be prepared by adding oxide of mercury to oxide of cacodyl, covered with a layer of water, and artificially cooled until the mixture loses all odour; any cacodylate of mercury which may have been formed is to be decomposed by the cautious addition of more oxide of cacodyl; by evaporation to dryness and solution in alcohol crystals of cacodylic acid are obtained, which have the following properties: They are colourless, brittle, brilliant, prismatic crystals; permanent in a dry atmosphere, but deliquescent in a moist one. Cacodylic acid is insoluble in ether, but dissolved by alcohol, and the solution has an acid reaction; it yields by combination with the alkalis and evaporation, a gummy mass; it forms crystalline compounds with the oxides of silver, mercury, &c.

From experiments tried on animals, it would seem, that cacodylic acid possesses little or no poisonous quality. This is somewhat remarkable, especially when we bear in mind that it contains more than half its weight of arsenic.

Cacodyl combines with various other bodies, yielding compounds which have been particularly described by Bunsen, and of which an account may be seen in a series of papers published by that eminent

chemist in Liebig's 'Annalen,' vols. xxxvii. xlii. xlv. [ORGANO-METALLIC BODIES.]

CACODYLATES. [CACODYL.]

CACODYLIC ACID. [CACODYL.]

CACOPLATYL (C_4H_6PtAs). This body may be represented as cacodyl in which two equivalents of hydrogen are replaced by one of diatomic platinum. When a mixture of solutions of chloride of cacodyl and bichloride of platinum are heated and allowed to cool, crystals of chloride of cacoplatyl separate out, the reaction is expressed in the following equation:—

Chloride of Cacoplatyl crystallises in beautiful needles. It is inodorous, and has a nauseous arsenical taste, is soluble in hot water and hot alcohol, and when heated darkens in colour, takes fire, and smoulders away, giving off arsenical fumes and leaving a fusible residue of arsenide of platinum. Sulphuric acid colours it yellow. It is very soluble in ammonia, and the solution yields on evaporation a crystalline body insoluble in alcohol.

The **Bromide of Cacoplatyl** (C_4H_6PtAs, Br) and the **iodide of cacoplatyl** (C_4H_6PtAs, I) are obtained by decomposing chloride of cacoplatyl with bromide or iodide of potassium. They are both beautifully crystalline, soluble in hot water, and have a disagreeable arsenical taste. They each contain two equivalents of water of crystallisation.

The **Sulphate of Cacoplatyl** is obtained by boiling chloride of cacoplatyl with a solution of sulphate of silver. It has the form of white crystalline grains, is very stable, without odour, and of a bitter and astringent taste. [ORGANO-METALLIC BODIES.]

CACOTHELINE. [NUX VOMICA, ALKALOIDS OF.]

CACTIN. When the flowers of the *Cactus speciosus* are extracted with alcohol they yield a carmine red colour, to which the name of cactin has been given. Its composition and properties are not known.

CADENCE, in Music (*cadenza*, Ital., *cadence*, Fr., from *cado*, Lat., *to fall*), the close of a musical passage or phrase, or the resolution of a dissonant chord into a consonant one.

Cadences, which are in some degree analogous to punctuation in grammar, are resting places for the mind, serving to divide a composition into several parts, or to separate the different members of a musical sentence. They are either perfect or imperfect. The perfect cadence is composed of the chord of the dominant, followed by that of the tonic; likewise of the chord of the dominant seventh, succeeded by that of the tonic.

EXAMPLES.

The first and second inversions of the dominant seventh, followed by the chord of the tonic, also form perfect cadences, but are rarely used as final cadences.

EXAMPLES.

The imperfect cadence consists of the chord of the tonic, followed by that of the dominant, but is never met with as a final close, except in some very few old ecclesiastical compositions.

Albrechtsberger gives the subjoined formulæ of this cadence.

No. 1.

No. 2.

But in No. 2, the introduction of the F sharp changes the key

G therefore is no longer the dominant, but becomes the tonic; consequently a composition thus ending terminates irregularly, and not with an imperfect cadence, if the accepted definition of the latter be correct.

Besides the perfect and imperfect cadences, many writers speak of the *interrupted* or *deceptive* cadence. It is formed by a chord quite foreign to that which was expected, thus evading the close, and deceiving expectation.

EXAMPLE.

There is also another kind of cadence, to which the name of *plagal* is given; and this is sometimes classed as an imperfect cadence. It consists of the chord of the subdominant, followed by that of the tonic, and is occasionally used in church and other sacred music.

EXAMPLE.

Sometimes in this cadence the chord of the subdominant is suspended on part of the final tonic.

EXAMPLE.

The term *cadence* is also used to signify the addition made by the performer at the close of an air or concerto, and supposed to be an extemporaneous effusion, for the purpose of displaying such taste, skill, and power as the composition itself affords no means of exhibiting. The *cadenza*, however, if introduced at all, should always be in good keeping with the air, &c., to which it is appended; it ought to preserve the same general character, and should invariably be brief, in the instance of vocal music especially. Formerly the *cadenza* was, by Italian as well as English singers, considered indispensable, and many were the incongruous flights of ill-regulated fancy that audiences had to endure. The French never admitted it; the Italians have now wisely discarded it; and the English have also begun to abandon it.

The *cadenza* is so called, says Rousseau, because introduced generally on the first note of the final cadence.

CADET, LIQUOR OF. [CACODYL.]

CADI, according to Mr. Lane ('Arabian Nights,' vol. i.), *Kádee*, is a judge or minister of justice, who passes sentence in all cases of law: religious, moral, civil, and criminal. This he generally does, in the present day, in accordance with the decision of a Mufti, or doctor of the law. In small towns and villages he is often employed to draw up written contracts of various kinds. The Persian pronunciation of the word is *Cázi*, sometimes written *Kazee* or *Kauzee*. In the Mohammedan states in India the *cádi* continues to be the chief judge; but in Turkey he is subject to the Mufti, and in Persia he stands under the Sheikh-ul-Islám or supreme judge (literally "the elder or chief of the faith"), in all the principal cities where an officer of that rank resides; and the latter functionary has in general the further gratuitous aid of the council of Mullás (Moollahs) or learned men.

The law of all Mohammedan nations, which is administered by the *cádis*, is founded partly on the Koran, and partly on the Sunnah or tradition; but in Persia, since the establishment of the faith of the Shiites as the national religion of the country, jurists have rejected all traditions coming from the three first caliphs, Abu Bekr, Omar, and Osman, or from other persons who opposed the right of Ali to the succession of Mohammed.

CADMIUM (Cd), *Klaprothium*, *Melinum*, a peculiar metal, discovered in 1818; it was found in some ores of zinc, and especially in the Silesian. On account of the effect which was produced by the action of sulphuretted hydrogen upon some preparations of zinc, the presence of arsenic was suspected, but the appearance was found to be owing to this new metal. The first notice of its existence was by Hermann, but Stromeyer more particularly examined and detailed its properties, and gave it the name of *cadmium*, from *cadmia*, *fossilis*, *calamine*, or *καδμεια*, a name by which the common ore of zinc was formerly known.

In order to separate cadmium from the mineral containing it, it is

to be dissolved in sulphuric acid, and the solution, which should have excess of acid, is to be diluted with water, and to have a current of sulphuretted hydrogen gas passed into it, until a yellow precipitate ceases to be formed. This precipitate is sulphuret of cadmium, which is to be dissolved in concentrated hydrochloric acid, and the excess of acid being expelled by evaporation, the residual salt is to be dissolved in water, and precipitated by carbonate of ammonia, an excess of which dissolves any oxide of zinc or copper that may have been thrown down by the sulphuretted hydrogen with the sulphuret of cadmium. The carbonate of cadmium thus obtained is to be heated to redness, to expel carbonic acid, then mixed with lamp black, and heated to dull redness in a glass or porcelain retort: it is thus reduced, and the metal distilled. The impure Silesian oxide of zinc is stated to contain from 1½ to 11 per cent. of this metal.

Cadmium has the colour of tin, is brilliant, and susceptible of a fine polish. Its fracture is fibrous, and it crystallises readily in regular octohedrons; while solidifying, its surface is covered with arborations like fern leaves. It is soft, easily bent, filed, and cut; it stains substances upon which it is rubbed, like lead. When bent it gives a peculiar crackling noise, like tin. It is very ductile, easily drawn into wire and beaten into thin leaves. Its specific gravity after fusion is 8.604, but when beaten 8.694. Cadmium melts below a red heat; and at a temperature a little below that of boiling mercury, it boils and distils in drops. The vapour of cadmium has no particular odour. Like tin it is slowly acted upon by the air, but is eventually tarnished by it.

Oxygen and Cadmium readily unite to form an oxide. It may be procured either by burning the metal, by decomposing a solution of the metal with an alkali and washing and calcining the precipitate, or by igniting the carbonate or nitrate. The colour of oxide of cadmium depends upon its state of aggregation; it is either deep reddish yellow, bright brown, deep brown, or even black. It is neither fusible nor volatile, even at a very high temperature. Oxide of cadmium is insoluble in water, but is precipitated in the state of hydrate by solution of potash; this hydrate is white, insoluble in the fixed alkalies, but soluble in ammonia. Carbonate of ammonia, however, does not dissolve it, and this difference between it and oxide of zinc serves as a process for separating them. Oxide of cadmium is composed of—

$$\begin{array}{rcl} 1 \text{ Equivalent of oxygen} & = & 8 \\ 1 \text{ " " cadmium} & = & 56.74 \end{array}$$

$$\text{Equivalent of oxide } 64.74$$

Suboxide of Cadmium (Cd_2O), containing two equivalents of metal to one of oxygen, is obtained when oxalate of cadmium is heated in a retort to the melting-point of lead. It is a green powder.

Nitrogen and cadmium form, according to Mr. Grove, a spongy, dark, lead-gray substance. Its specific gravity is 4.8.

No compound of hydrogen and cadmium is known.

Chlorine and Cadmium combine to form only one chloride; this compound may be obtained by dissolving either the metal or its oxide in hydrochloric acid. The solution, by spontaneous evaporation, is gradually converted into a mass of short satiny crystals, composed of—

$$\begin{array}{rcl} 1 \text{ Equivalent of chlorine} & = & 35.5 \\ 1 \text{ " " cadmium} & = & 56.74 \\ 2 \text{ " " water} & = & 18 \end{array}$$

$$110.24$$

These crystals are readily soluble in water, and effloresce in warm dry air. The effloresced salt fuses below a red heat, and on cooling it assumes the appearance of a transparent, lamellated, crystalline mass, which has a faint, pearly, metallic lustre. By exposure to the air it acquires water, and falls to powder.

No compound of carbon and cadmium is known.

Sulphur and Cadmium unite to form only one sulphide, which consists of—

$$\begin{array}{rcl} 1 \text{ Equivalent of sulphur} & = & 16.00 \\ 1 \text{ " " cadmium} & = & 56.74 \end{array}$$

$$\text{Equivalent of sulphide } 72.74$$

This metal does not readily unite with sulphur when they are heated together. The compound is more easily formed when the oxide is heated with it, but the best method is to precipitate a salt of cadmium with sulphuretted hydrogen. In this state it forms a pigment known as *jaune brilliant*. It has a yellow colour, inclining to orange. It was this colour which first led to the suspicion that zinc contained arsenic. When heated to redness it becomes brown, and afterwards carmine red, but on cooling it resumes its original colour. It is not decomposed at a high temperature; but a strong white heat melts it, and causes it to crystallise on cooling in transparent plates of a fine yellow colour. Concentrated hydrochloric acid decomposes it with the evolution of sulphuretted hydrogen, and without any deposit of sulphur. Nitric acid converts it into sulphate of cadmium. Sulphide of cadmium is insoluble in sulphide of ammonium; this serves to distinguish it from sulphide of arsenic, which is soluble in that reagent.

Sulphide of cadmium is also found native in the form of *Greenockite*.

Phosphorus and Cadmium combine readily; the resulting phosphide

is gray, has a weak metallic lustre, is brittle, and but slightly fusible. When heated in open vessels it burns with a very bright phosphoric flame, and is converted into phosphate of cadmium. It dissolves in hydrochloric acid with the evolution of phosphuretted hydrogen gas.

Iodine and Cadmium may be made to combine by treating the metal with iodine, either in the moist or dry way. Iodide of cadmium forms large hexagonal tubular crystals, which are colourless and transparent, have a shining pearly lustre, and do not alter by exposure to the air. This salt is readily soluble both in water and in alcohol. The crystals fuse readily, losing their water of crystallisation, and again crystallising. At a higher temperature this salt is decomposed, iodine vapourising, and metallic cadmium being left. It is composed of—

1 Equivalent of iodine	= 126.80
1 " " cadmium	= 56.74
Equivalent = 183.54	

Iodide of cadmium as an external remedial agent is said to be superior to all other iodides used for that purpose. It is not decomposed by air or light, and hence preference is given to it in the preparation of iodised collodion for photographic experiments.

Bromine and Cadmium combine at a red heat, forming bromide of cadmium. It readily fuses, and at a high temperature sublimes in white pearly laminae. It is soluble in water, and on evaporation is obtained in white needles containing—

1 Equivalent of cadmium	= 56.74
1 " " bromine	= 80.00
1 " " water	= 36.00
Equivalent 172.74	

Fluorine and Cadmium form a fluoride which is but little soluble in water, but more so when acid is in excess. On evaporating the solution an irregular crust is deposited, which adheres to the vessel. It is composed of—

1 Equivalent of fluorine	= 19.00
1 " " cadmium	= 56.74
Equivalent = 75.74	

The various oxy-acids combine with oxide of cadmium to form salts, the general properties of which are, that a considerable number of them are soluble in water, and the solutions are in general nearly or quite colourless: the insoluble salts are also commonly devoid of colour. The soluble salts are decomposed by ammonia and the fixed alkalies, they throwing down white hydrate of cadmium, which an excess of ammonia re-dissolves. The alkaline carbonates precipitate white carbonate of cadmium; sulphuretted hydrogen occasions a yellow deposit; ferrocyanide of potassium, a white one; and infusion of galls produces no effect. A plate of zinc throws down metallic cadmium.

The cadmium salts have a disagreeable metallic taste, and are powerfully emetic.

Nitrate of Cadmium crystallises in radiating needles, which attract moisture from the air, and are very soluble in water and alcohol. This salt consists of—

1 Equivalent of nitric acid	= 54.00
1 " " oxide of cadmium	= 64.74
4 " " water	= 36.00
Equivalent = 154.74	

Carbonate of Cadmium is readily obtained by adding a solution of carbonate of soda to one of nitrate of cadmium. It is a white insipid powder which is insoluble in water. When heated it is decomposed, owing to the expulsion of the carbonic acid. It is constituted of—

1 Equivalent of carbonic acid	= 22.00
1 " " oxide of cadmium	= 64.74
Equivalent = 86.74	

Sulphate of Cadmium crystallises in large transparent prisms, much resembling sulphate of zinc in appearance. This salt readily dissolves in water. It effloresces when exposed to the air, and at a low heat loses its water of crystallisation without fusing. The dry salt is not easily decomposed, a low red heat not being sufficient to expel the sulphuric acid; but at a higher temperature it loses part of its sulphuric acid, and becomes a subsulphate. Its constituents are—

1 Equivalent of sulphuric acid	= 40.00
1 " " oxide of cadmium	= 64.74
4 " " water	= 36.00
Equivalent = 140.74	

Acetate of Cadmium crystallises in fine needles, which are readily

soluble in water, and do not alter in the air; they are composed of—

1 Equivalent of acetic acid	= 51.00
1 " " oxide of cadmium	= 64.74
2 " " water	= 18.00
Equivalent = 133.74	

These are the most important crystallisable salts of cadmium; with phosphoric, boracic, oxalic, arsenic, tartaric, and citric acids, oxide of cadmium forms salts which are nearly or quite insoluble in water. It forms also double compounds with several salts of the alkalies.

Alloys of Cadmium.—Several metals readily combine with cadmium, and form with it brittle alloys, and when they are strongly heated the cadmium is volatilised.

Copper and Cadmium form a yellowish white brittle alloy, and a small quantity of cadmium is sufficient to produce this effect; 100 parts of copper retain 82.2 of cadmium when exposed to a red heat, but when the alloy is heated to the fusing point of copper, the cadmium is volatilised entirely.

Platinum and Cadmium yield an alloy which is of a silver white colour, brittle, and not readily fusible; 100 parts of platinum retain 117.3 of cadmium at a red heat.

Mercury and Cadmium readily unite, and form a fine argentine amalgam, which crystallises in octohedrons. The crystals fall to the bottom of the mercury, and are consequently of greater specific gravity. The saturated amalgam is composed of 78.26 of mercury, and 21.74 of cadmium.

Cadmium not having been long discovered, no very great use has been made of it. If larger quantities of it should be obtained, its malleability may render it useful for several purposes. Sulphate of cadmium has been used in medicine as a substitute for that of zinc in collyria, but whether with any advantage over it has not been determined.

CADMIUM, ORES OF. Properly speaking, no ore of this metal has yet been discovered, except the sulphide mentioned; for it occurs in such small quantities in the other minerals in which it has been detected, that it may rather be considered as an accidental impurity than an essential constituent part. It is thus usually found associated with the ores of zinc, the greatest proportion being found by Stromeyer to be about five per cent. in the radiated zinc-blendes of Bohemia. It has also been found by Dr. Clarke in the oxides of zinc, both of Freiburg and Derbyshire; and its presence may also be generally detected in the common zinc of commerce, and may usually be obtained in considerable quantity mixed with the soot from the crucibles in which the oxides of zinc are reduced by being heated with coal. Portions of this substance from the zinc works of Bristol were found to contain from 12 to 20 per cent. of cadmium.

CADUCEUS, a staff of laurel or olive, with a representation of two snakes twisted about it. The caduceus was a symbol of Hermes or Mercury, to whom, according to the fable, it was given by Apollo, in return for the lyre which Mercury had presented to him. It was also the badge of the heralds of ancient Greece; and the name, which is also written Caduceum, is apparently only a corruption of the Greek κηρύκειον (kerykeion), herald's staff. In its oldest form it was merely a bough, like the Greek ἱκετήριον (hiketérion), and the Roman supplicia, twined about with white wool. Afterwards a white or gilded staff, with imitations of foliage and ribands, was substituted for the old rude symbol. These were probably not turned into snakes till a much later age, when that reptile had acquired a mystic character. Many explanations of the caduceus have been attempted by modern scholars; that of Böttiger is plausible, who supposes that it was a representation of a peculiar knot (the *nodus Herculis*, Macrob. I., Saturn. c. 19) used by the Phœnicians in cording up their packages, and thence adopted by them as a means of signifying to the inhabitants of the countries on which they landed, their wish to be upon a friendly footing with them; and as the Phœnicians were, generally speaking, the first strangers with whom any people of Greece had intercourse, their symbol of amity would probably be used for the same purpose, whenever an occasion offered. (Böttiger, 'Vasengemälde,' part ii. p. 97; 'Amalthea,' vol. i. p. 116); but the most probable, as it is the most simple, is that of Müller, who says that it was originally the olive-branch with the στέμματα, which later became developed into serpents. ('Archäologie der Kunst,' § 379.)

CÆLUM SCALPTORIS, the sculptor's tool, a constellation of Lacaille. It is situated below Columba Noachi and Canis Major, low enough not to rise in this country. The following are the principal stars in this constellation:—

Character.	No. in Catalogue of Piazz.	No. in Catalogue of British Association.	Magnitude.
δ	129	1413	4
α	175	1458	4
β	181	1464	4
γ	308	1573	4

CÆSURA, or its Greek equivalent τομή (that is, cutting, the two words being respectively derived from the stems *caed* and *tem*, cut), is

the name given by ancient grammarians to the division of a verse into two or more portions by a pause or pauses, the position of which must be consistent both with the rhythm of the metre and the meaning of the words. If in any metre the termination of every foot coincide with the termination of a word, a painful monotony arises which would soon offend the ear; as in the lines,—

Sparsis hastis longis campus splendet et horret.—*Enn.*
Disperge hostis, distrahe, diduc, divide, differ.—*Enn.*
Has res ad te scriptas Luci misimus Aeli.—*Lucil.*

This has led some grammarians to hold the opinion that the several feet of a verse should be blended together; yet this principle might lead to results no less offensive than the lines that have been just quoted, as may be seen in the following verses:—

Sole cadente juvenecus aratra reliquit in arvo.

Πολλα δ' ἀνὰ κατὰ παρὰ τε δοχμὰ τ' ἦλθον.

Much that has been written about the cæsura betrays an inaccuracy which has arisen from a neglect of the principle of accent. Those who define verses by the mere order of the long and short syllables find it necessary afterwards to lay down what appear to be arbitrary canons. Thus a word of three long syllables, such as *prorumpunt*, might, according to the usual definition of an hexameter verse, occupy any place which did not interfere with the two short syllables of the fifth foot. Yet an ear acquainted with the true rhythm of this verse would be violently offended by any line beginning with *Et prorumpunt*, or *Continuo prorumpunt*, or *Continuo nostri jam prorumpunt ululantes*. The true objection to these lines is that the accent of the word *prorumpunt*, which of course falls upon the penult, is inconsistent with the demands of the verse, which, in the positions here given to the word, would compel us to falsify the accent, and pronounce *prórumpunt*. [HEXAMETER.] A part of these difficulties they evade by adding to the previous definition of the hexameter a canon to the effect that there must always be a cæsura at the end of two feet and a-half, or three feet and a-half, with the additional proviso that the syllable immediately preceding the cæsura must not be a monosyllable. To this canon there are two serious objections besides its arbitrary character: one that it does not exclude *prorumpunt* from its position in the third example; the other that it lays down a rule which is violated in many of the finest verses of the *Æneid*. The same neglect of accents has led to precisely the same difficulties in the other metres.

The name of cæsura or *τομή* (or *κόμμα*, which has the same meaning) is sometimes given to that portion of a verse which precedes the pause. Thus when the pause occurs at the end of the fourth foot of the hexameter, that fourth foot being a dactyl, which is common in the bucolic writers, the four first feet so cut off bear the name of a bucolic cæsura.

CAFFEIC ACID. [TANNIC ACIDS.]

CAFFEINE, *Théine*, *Guaranine* ($C_{10}H_{10}N_4O_4 + 2Aq.$). A crystalline alkaloid found in coffee, tea, and two other vegetable preparations, namely, in guarana, a paste prepared from the seeds and other parts of the *Paullinia sorbilis*, and in the leaves of *Ilex Paraguayensis*, both of which are used in the production of beverages in the Brazils and a few other parts of the world. Caffeine was first discovered in coffee by Runge in 1820, and a few years afterwards in tea by Oudry, who called it *théine*: the identity of the two substances has since, however, been fully established.

It exists, according to Payen and other chemists, in combination with potash and chlorogenic, caffeic, or caffetannic acid, and is best prepared as follows: A decoction of tea or coffee is mixed with excess of solution of basic acetate of lead and filtered; through the clear liquid is passed a current of sulphuretted hydrogen, the sulphide of lead separated by filtration, and the filtrate evaporated to a small bulk. On cooling the caffeine crystallises out nearly pure, and may be rendered quite white by boiling in water or ether with a little powdered animal charcoal, filtering and recrystallising.

So obtained, it presents the appearance of long silky needles. They contain 8.4 per cent. of water, which is not thoroughly separated below a temperature of 302° . At 352° they melt, and at a higher heat sublime without decomposition. It is readily soluble in ether; also in boiling alcohol or boiling water, but from these it nearly all crystallises out on cooling. Heated with strong alkalis it is decomposed with production of methylamine. Hydrochloric acid dissolves it, but on evaporation it is deposited unchanged. Caffeine, nevertheless, does possess basic properties, and, by carefully avoiding the presence of water, several well-defined salts may be obtained. The most remarkable and beautiful of these are the double chlorides with platinum, gold, and mercury.

Caffeine is powerfully attacked by oxidising agents, giving rise to several bodies of considerable interest, inasmuch as they establish its intimate connection with the uric group of the formic series of organic compounds. These are: 1st, amalic acid, obtained by Rochleder on passing a current of chlorine through caffeine suspended in water, stopping the gas before the caffeine is all dissolved, filtering and evaporating the filtrate; 2nd, Cholestophane (the nitro-théine of Stenhouse); obtained by the prolonged action of chlorine or nitric acid; and 3rd, Murexoin, obtained by the action of ammonia on amalic acid. These bodies are homologous with alloxantine, parabanic

ARTS AND SCI. DIV. VOL. II.

acid, and murexid (compounds obtained by similar processes from uric acid), and differing only from these latter by having equivalents of the radical methyl (C_2H_5) in the place of an equal number of equivalents of hydrogen. The following diagram will show this at a glance:—

The use of caffeine as an article of diet has not yet been satisfactorily ascertained. That this is a question of no mean interest is obvious when we consider that it exists in four substances differing widely from each other in their botanical origin, and yet all instinctively used for the same purpose by the various nations of the world, namely, the production of useful and agreeable beverages. Liebig suggests that it contributes to the formation of taurine, a compound peculiar to bile. He considers bile to be one of the products of the decomposition of animal tissues, and has lately found caffeine in muscular flesh. Lehman has found that its administration is always followed by a slight augmentation of the secretion of urea.

CAFFEO-MUREXID. [CAFFEINE.]

CAFFETANNIC ACID. [TANNIC ACIDS.]

CAFFILA is the term used in Northern Africa for those companies of travelling merchants which in Asia are called caravans. The order in which they are arranged is the same, but the caffilas being generally less numerous than the caravans, this order is not so strictly observed.

CAIMACA'N, more properly *Kaimakam*, a Turkish name which corresponds to our lieutenant, or rather lieutenant-governor. The caimacan of Constantinople is the lieutenant of the grand vizir, whom he represents in processions when absent. It is an office of importance, and the person who fills it is generally styled pasha. (La Croix, 'Mémoires sur l'Empire Ottoman.') The pashas or governors of provinces have also their caimacans or lieutenants, who often act as governors of the principal towns.

CAINCIC ACID ($C_{32}H_{20}O_{14}$?). This acid is obtained from the root of the *Chiococca anguifuga*, a plant employed in the Brazils as an antidote for the bite of serpents. It is also contained in the root of the *Chiococca racemosa*. The acid is extracted by digesting the powdered root in alcohol, concentrating the alcoholic extract, then adding water and filtering. The filtered liquor is treated with milk of lime, by which an insoluble sub-caincate of lime is produced. This salt is then to be decomposed by a hot alcoholic solution of oxalic acid; when, after filtration and cooling, the caincic acid is deposited in the form of small needles.

Caicic acid is inodorous, bitter to the taste, reddens litmus, dissolves in 600 parts of water, but is much more soluble in alcohol. Acids and alkalis transform it into *quinovatic acid* and grape sugar. Taken internally, caicic acid acts as a powerful diuretic.

CAIRN, a heap of stones piled over the remains of the dead. Lhuyd, in his 'Additions to Camden's Britannia in Radnorshire, asserts that in the Cambro-Britannic *Kaern* is a primitive word, appropriated to signify such heaps of stones. Cairns and tumuli of earth were the common monuments which the ancient Britons, like the Northern races generally, erected in honour of their great men, as indeed they appear to have been of the most aboriginal races. [TUMULUS.] Which of the two kinds was to be adopted was probably determined by the circumstance of the country being stony or otherwise.

Pennant, in his 'Voyage to the Hebrides,' 1772 (4to. Lond. 1790, vol. ii. p. 208), speaking of the cairns, says, "These immense accumulations of stones are the sepulchral protections of the heroes among the ancient natives of our islands: the stone chests, the repositories of the urns and ashes, are lodged in the earth beneath; sometimes one, sometimes more, are found thus deposited; and I have one instance of as many as seventeen of these stone chests being discovered under the same *cairn*. The learned have assigned other causes for these heaps of stones; have supposed them to have been, in times of inauguration, the places where the chieftain-elect stood to show himself to the best advantage to the people; or the place from whence judgment was pronounced; or to have been erected on the road-side in honour of Mercury; or to have been formed in memory of some solemn compact." (See Rowland's 'Mona Antiqua,' p. 50; Borlase's 'Antiq. of Cornwall,' p. 209.) These opinions were once very prevalent, but it is now generally said that the cairn was simply monumental.

"These piles," Pennant adds, "may be justly supposed to have been proportioned in size to the rank of the person, or to his popularity: the people of a whole district assembled to show their respect to the deceased, and by an active honouring of his memory soon accumulated heaps equal to those that astonish us at this time. But these honours were not merely those of the day; as long as the memory of the deceased existed, not a passenger went by without adding a stone to the heap: they supposed it would be an honour to the dead, and acceptable to his *manes*. To this moment," he continues, "there is a proverbial expression among the highlanders allusive to the old practice: a suppliant will tell his patron, *Curri mi cloch er do charne* (I will add

K K

a stone to your *cairn*), meaning, when you are no more I will do all possible honour to your memory." Cairns or remains of cairns, are found throughout the British islands; in France, (especially in Brittany); also, but rarely as compared with earthen tumuli, in Germany, Sweden and Denmark, and other parts of Europe.

Jamieson, in his 'Etymological Dictionary,' says, "In Angus, where any person has been murdered, a cairn is erected on the spot." [TUMULUS.]

CAISSON. A water-tight vessel used in hydraulic engineering, for the purpose either of closing the entrance to a dock, or any similar work; or of receiving the foundations of a building, which are subsequently sunk upon a bed formed to receive them, and the caisson itself. In 'Vitruvius de Architectura,' lib. 5, cap. 12, there is a description of the mode of employing a species of caisson, or enclosure, to receive the commencement of works to be erected in deep water, which differs little from that still used by the Italian engineers; but the first instance on record of the use of caissons on a large scale, was in the case of the New Westminster Bridge, executed under the orders of Labeleye, a Swiss engineer, about the year 1740. The next instances of their application were in the case of the bridge of Saumur, about 1757, and in many other important works erected by De Cessart. In England, Smeaton and Semple frequently employed this method of executing the foundations of buildings to be erected in deep water; and the former even adopted it in the case of the Ramsgate harbour. It has, however, been found, practically, that if the substratum upon which a caisson is sunk should be susceptible of being undermined, there is great danger of the superstructure being also carried away; and, at the present day, the use of caissons for foundation purposes is almost exclusively confined to such positions as offer naturally a rocky substratum. Caisson gates are, however, still extensively used in dockworks, especially when the gates are not obliged to be frequently opened; and it is for this reason that they are more commonly to be met with in military than in commercial ports.

The caissons formerly used for foundation purposes were in fact timber frames large enough to receive the whole of the intended base. These frames were brought over the position they were meant subsequently to occupy, and which had been prepared to receive them by dredging, or by the use of the diving-bell; and when the masonry of the proposed structure had been raised to a sufficient height, the frame was pierced and sunk. Evidently in such cases the success of the operation depended upon the equal resistance of the ground to be covered, and upon its subsequent powers of resistance to the undermining action of the currents; conditions which can hardly ever be secured in practice. Moreover, it is almost impossible to secure the perfectly vertical position of the mass to be sunk, and thus the defects of the substrata become exaggerated. When caissons are used upon rocky strata, it is customary to make them open at both ends; and, at the present day, to fill them in entirely with concrete, as was done at Rochester and Saltash.

A species of caisson was suggested by Coulomb, in a very curious treatise 'Sur les moyens d'exécuter sous l'eau toutes sortes de travaux hydrauliques,' 8vo, Paris, 1779, which has been subsequently adopted and improved, in England and in France, in a manner to be noticed hereafter under FOUNDATIONS.

CAJUPUT OIL. This oil is obtained from the leaves of the *Melaleuca minor*, a tree of the natural order Myrtaceæ. The wood of the tree is white, hence the name cajuput (*kayu-puti*, white wood). It grows in the Molucca isles. The leaves are packed in sacks, allowed to ferment for a short time, and then distilled with water, when the oil is carried over with the steam and floats on the condensed liquid.

Cajuput oil as imported is of a green colour, limpid and transparent. It has an aromatic odour, and a taste somewhat resembling camphor. Its specific gravity is usually 0.92. Boiling point 347° Fahr. It may be purified by redistillation. Its chemical composition is, according to Blanchett, $C_{20}H_{18}O_2$. Cajuput oil is soluble in alcohol, without acid reaction, and when pure is quite colourless. It has been asserted that the colour of the oil is owing to the presence of copper derived from the vessels in which it has been stored: this is not the case; the colour is due to chlorophyll, or a matter closely resembling chlorophyll.

Cajuput oil is a medicinal agent. Internally it acts as a diffusible stimulant and antispasmodic, externally as a sudorific.

CALAMINE. [ZINC, CARBONATE OF.]

CALAMUS. [DRAGON'S BLOOD.]

CALCINATION. This chemical term is derived from *calx*, the Latin for quicklime, which, as well known, is prepared by the action of heat upon limestone: the old chemists, therefore, employed the word calcination to express any supposed analogous change; for example, when certain metals, as tin and zinc, are exposed to heat and air, they were said to be *calcined*, and the product was called a *calx*, as of tin or zinc.

It will be observed, therefore, that different operations were included in this term: first, the expulsion of carbonic acid, as when lime is prepared; secondly, the acquisition of oxygen when the metals are heated, and the results of the action of heat and air upon them were termed *calces*: thus calx of tin is now called oxide of tin.

The term calcination is yet employed to express the separation of the volatile from the more fixed parts of a body: thus bones which are heated till they become black are termed *burnt bones*; but when, by the further operation of heat, they become white, they are called

calcined bones; so also we say calcined flints, calcined clay, sulphate of lime, &c. But what were formerly termed metallic calces or calcined metals are now described as metallic oxides.

CALCIUM (Ca), a peculiar metal, of which lime is the well-known oxide. It was first obtained by Davy, in 1808, by the action of voltaic electricity; he made chalk or carbonate of lime into a paste with water, and placing it on a plate of platinum, a cavity was made in the paste to receive a globule of mercury. The mercury was rendered negative and the platinum positive by means of a battery of about 100 double plates. In this way the lime being decomposed, its metal formed an amalgam with the mercury. This amalgam was distilled in glass tubes filled with the vapour of naphtha. In an experiment in which the greater part of the mercury was expelled, the tube broke whilst warm, air entered, the metal, which had the colour and lustre of silver, instantly took fire, and burnt, with an intense white light, into lime.

Calcium has been recently investigated by Dr. Matthiesen, who obtained a considerable quantity of it by the electrolytic decomposition of a fused mixture of the chlorides of calcium and strontium, in the proportion of two equivalents of the former to one of the latter. For details of the operation, see 'Quarterly Journal of the Chemical Society,' vol. viii. p. 28.

The specific gravity of calcium is 1.578. It is of a very light gold colour, is malleable and ductile, and possesses a hardness intermediate between lead and gold. Exposed to the air at ordinary temperatures it soon tarnishes by combining with oxygen, and at a red heat melts, and in a current of air burns with a dazzling white light, at the same time throwing off beautiful scintillations. It also burns brilliantly in an atmosphere of chlorine, bromine, iodine, or sulphur. It rapidly decomposes water, setting free and taking the place of the hydrogen. These properties of calcium have still more recently been confirmed by MM. Liès-Boudart and Jobin, who have obtained it by the action of sodium on iodide of calcium at a red heat in closed iron vessels. They fix its spec. grav. at 1.55. Compounds of calcium with other elements have been long known and extensively employed; the first we shall mention is lime, resulting from the union of

Oxygen and Calcium: these substances combine to form two compounds; namely, lime, or the protoxide of calcium, and the peroxide of calcium. It has just been mentioned that calcium and oxygen unite with great force of affinity, which of course prevents calcium from occurring in nature uncombined with this element. Lime has been known from the remotest antiquity, and is one of the most abundant and universally diffused substances in nature. It is never found pure, but always combined either with other earths, or more generally with acids; for example, with carbonic acid in marble, chalk, limestone, and calcareous spar, and in the shells of fish and eggs of birds; with sulphuric acid it constitutes sulphate of lime, or gypsum; with phosphoric acid it forms the earthy part of animal bone; and with silica and other earths it enters into the composition of many minerals and precious stones.

Lime (CaO) is easily obtained in a pure state: the carbonate or any limestone free from impurity is to be mixed with coal or charcoal and exposed to a strong heat; in this way the carbonic acid is expelled, and the lime, or oxide of calcium, remains: this is, in fact, the common process of lime-burning, and the product is frequently called quick-lime.

Lime is composed of—

1 Equivalent of calcium =	20
1 " oxygen =	8
	—
Equivalent =	28

The properties of lime are: It is white, opaque, inodorous, and its taste is acrid and alkaline; its specific gravity is 3.15. It is infusible in the strongest furnaces; but small quantities have been fused by the oxy-hydrogen blowpipe. By exposure to the air it attracts moisture and carbonic acid, and falls to powder. Lime has great affinity for water; the compound is solid, and called *hydrate of lime*. *Lime-water* is a solution of hydrate of lime in water.

Hydrate of Lime (CaO, HO), or, as it is usually called, *slaked lime*, to distinguish it from *quick-lime*, is readily prepared by sprinkling this earth with water; it almost immediately heats, cracks, swells, and becomes powdery. During this operation part of the water is rendered solid and combines with the lime, while another portion is expelled in vapour, light as well as heat being evolved; indeed the degree of heat has been found sufficient to set fire to buildings in which lime has been accidentally exposed to water.

When quick-lime is exposed to the air it gradually absorbs both water and carbonic acid, falls to powder, and in that state is termed *air-slaked lime*.

Lime-water is easily prepared by adding the earth to water, but it is better to employ the hydrate for this purpose; and it is a curious circumstance, first noticed by Dr. Priestley, that cold water dissolves a larger quantity than hot: thus an imperial pint of boiling water dissolves only $6\frac{1}{4}$ grains of lime, but at near 32° it takes up almost exactly $13\frac{1}{4}$ grains. When lime-water prepared with cold water is heated to ebullition it deposits crystals of lime; but it does not part with any at common temperatures.

Lime-water has a disagreeable taste, and the alkaline property of

turning vegetable yellows brown and blues green. When it is exposed to the air the lime speedily attracts carbonic acid, and pellicle after pellicle of carbonate of lime being formed, the whole of the lime is eventually precipitated: hence the necessity of keeping this solution out of the contact of air.

Milk of Lime is merely hydrate of lime diffused through water. It is best prepared by slaking quick-lime with hot water, and adding cold water till the required consistence is obtained.

Lime is employed for a vast number of purposes in common life, the arts, and manufactures. Among its most important applications are the making of mortar and other cements, and the amelioration of certain soils; it is extensively used also in soap-making, leather-dressing, dyeing, and for various medicinal purposes.

Peroxide of Calcium (CaO_2) was discovered by Thénard; he procured it by the gradual addition of lime-water to peroxide of hydrogen. Small brilliant scales are soon formed, but if much lime-water be added at once then the peroxide of calcium is pulverulent; it is in the state of hydrate, and decomposes spontaneously, losing its excess of oxygen even when left under water, and also by drying *in vacuo*. Neither nitrogen nor hydrogen combines with calcium.

Chlorine and Calcium form one chloride (CaCl). This compound may be formed by direct action, or by passing chlorine gas over lime heated to redness in an earthen tube, oxygen gas is expelled and chloride of calcium remains. It is however more easily procured by saturating hydrochloric acid with lime or chalk, evaporating the solution to dryness, and exposing the residue to a red heat to expel the whole of the water. In this operation the hydrogen of the hydrochloric acid unites with the oxygen of the oxide of calcium; water is formed and expelled, while the metallic chloride remains.

If after evaporating the solution of chloride of calcium to dryness the residue be heated not higher than about 350° , a white porous chloride is obtained, containing two equivalents of water. In this state it is well adapted for drying gases.

The properties of chloride of calcium (formerly called muriate of lime) are: It is colourless, possesses a crystalline appearance when broken, is inodorous, and has an extremely bitter saline taste. It is very deliquescent, and on account of this property it is frequently employed in chemical researches to separate water from gases in order to render them dry, and also to combine with this fluid and with alcohol in various other cases. It fuses readily by heat. Chloride of calcium, after being heated, shines in the dark, and was formerly called Homberg's phosphorus.

When a concentrated aqueous solution of this salt is suffered to cool, crystals are deposited, which, like the anhydrous chloride, are extremely deliquescent. They consist of—

1 Equivalent of chloride of calcium	=	55.5
6 " water	=	54.0
Equivalent	=	109.5

These crystals are remarkable for the great degree of cold which they occasion when mixed with snow; but the anhydrous chloride dissolves in water with the extrication of heat. The crystals are soluble in one-fourth their weight of water at 60° . The amount of chloride of calcium present in an aqueous solution is most conveniently determined by the specific gravity of the liquid. Thus:—

Sp. gr.	Per cent.	Sp. gr.	Per cent.
1.45	41.91	1.21	23.93
1.42	40.43	1.18	20.85
1.39	38.31	1.15	17.60
1.36	36.49	1.12	14.42
1.33	34.57	1.09	11.23
1.30	32.35	1.06	7.66
1.27	29.67	1.03	3.95
1.24	26.86		

Bromide of calcium (CaBr) is obtained by dissolving chalk in hydrobromic acid. It is a colourless, bitter, deliquescent substance, which readily dissolves in water, with the evolution of heat. The aqueous solution does not easily yield crystals; they contain much water.

Bromate of lime (CaO, BrO_3) is prepared by saturating bromic acid with lime or its carbonate.

Iodide of calcium (CaI). Best made by decomposing sulphide of calcium with iodine, filtering, evaporating to dryness, and heating out of contact of air. The resulting flaky mass has a pearly lustre. It may be easily powdered.

Iodide of calcium is soluble in water, a hot solution yielding long needles of hydrated salt.

Iodate of lime (CaO, IO_3), a crystalline compound obtained by double decomposition of iodate of potash and chloride of calcium.

Carbon and calcium form no compound.

Sulphur and calcium may be made to unite in three proportions. The sulphide, or proto-sulphide (CaS), is obtained by mixing anhydrous sulphate of lime with one-fifth of its weight of powdered charcoal, and heating the mixture to whiteness for two hours in a covered crucible. It is a reddish-white compound, which is but slightly soluble in water, and suffers but little change even when long kept in it. The aqueous

solution is colourless, and has an alkaline and hepatic taste; when evaporated *in vacuo*, white crystals of the sulphide are formed. When acted upon by hydrochloric acid, sulphuretted hydrogen gas is evolved. After exposure to light, this sulphide shines in the dark, and has been called Canton's phosphorus.

Bisulphide of calcium (CaS_2) is obtained by boiling, but not to saturation, hydrate of lime and sulphur in a large quantity of water. On cooling, yellow needle-shaped crystals are obtained, which are soluble in 400 times their weight of water at 60° , but more so in boiling water, and contain about 43.5 per cent. of water. When lime and sulphur are boiled together in water, till sulphur ceases to be taken up, *persulphide* or *pentasulphide of calcium* is formed, consisting of

1 Equivalent of calcium	=	20
5 " sulphur	=	80
Equivalent	=	100

Phosphorus and calcium constitute the phosphide (Ca_3P), and like all the binary compounds of this metal hitherto described, except the oxide, it is entirely an artificial product. It is prepared by heating lime in a crucible, and passing vapour of phosphorus into it:

The mixture of phosphate of lime and phosphide of calcium procured is of a brown-red colour.

This phosphide readily decomposes water, and phosphuretted hydrogen gas is evolved; when dissolved in hydrochloric acid this gas is abundantly procured.

Selenium and calcium may be combined by exposing a mixture of selenium and lime to a heat a little below redness. The resulting impure selenide is a brownish-black substance, which has neither smell nor taste, and is insoluble in water; when heated to redness it loses selenium, and selenide of calcium remains. Crystals of this substance may be formed by preparing a solution of lime in hydroselenic acid and exposing it to the air. It is composed of

1 Equivalent of calcium	=	20.00
1 " selenium	=	39.62
		59.62

No compound of boron and calcium is known.

Fluorine and calcium occur largely in nature, in combination, and form *fluoride of calcium* (CaF , Equiv. 39), called by mineralogists fluor spar. [FLUOR SPAR.]

Cyanogen and calcium form a cyanide which has been but slightly examined; it is obtained by saturating hydrocyanic acid with hydrate of lime. It exists only in solution; by evaporation it is converted into formate of lime and ammonia.

Oxy-acids and lime combine to form a numerous class of salts; of these, the most important only are here described. Two of them—namely, the carbonate and sulphate—occur in great plenty in almost every part of the earth; the phosphate is more rarely met with.

Nitric acid and lime very readily combine and yield nitrate of lime (CaO, NO_3). It may be formed either by adding lime or chalk to nitric acid. A colourless solution is obtained, which is extremely bitter, and by evaporation long prismatic crystals are formed ($\text{CaO}, \text{NO}_3 + 4\text{Aq.}$); like the anhydrous salt, they are extremely deliquescent. These crystals dissolve in one-fourth of their weight of cold water, and in all proportions in boiling water; they are also very soluble in alcohol. Nitrate of lime is readily decomposed by heat; the residue gives a feeble light in the dark, and has been called *Baldwin's phosphorus*; it is stated to be composed of nitric oxide, nitrous acid, and lime, but when the heat is very long continued then pure lime is obtained. Nitrate of lime is often found in considerable quantity in spring water. It is applied to no use.

Carbonic acid and lime form carbonate of lime. [CALCAREOUS SPAR.]

Carbonate of lime (CaO, CO_2) constitutes the greater part of all shells, and enters into the composition of bones. Like sulphate of lime, it is found in most spring waters, held in solution by an excess of carbonic acid, and to this in part the hardness of water is owing.

By boiling water containing carbonate of lime dissolved in carbonic acid, the latter is expelled and the former precipitated. Such water will of course be softer than in its original condition, and hence carbonate of lime is said to produce *temporary* hardness, while sulphate of lime, not being affected by ebullition, gives *permanent* hardness to water. Both salts are decomposed by soap, which forms the familiar, insoluble, curdy precipitate (*margarate* and *stearate of lime*), and it is not until all the lime is removed in this way that a permanent lather can be obtained. Moreover, in using hard water for domestic purposes, that portion of the insoluble lime-soap precipitated in the pores of the skin, or in the fibre of fabrics submitted to cleansing operations, carries down with it, like the mordant in the process of dyeing, a portion of the colouring matter, the removal of which is the object of the operator. For these reasons, carbonate and sulphate of lime may be considered as impurities in water; at the same time, it must be borne in mind, that a certain quantity of these and other salts probably prevent lead from being dissolved from pipes through which the water

may pass, and thus form a guarantee against the poisonous effects of a solution of that metal. [WATER.]

Carbonate of lime may be artificially procured by several processes, as by passing carbonic acid gas into lime-water, or by adding an alkaline carbonate to a solution of any salt of lime in water. The precipitate is at first bulky, but in a short time settles so as to occupy comparatively little space. Carbonate of lime is insoluble in water, and decomposed by most acids with the evolution of carbonic acid gas. It is in various forms largely employed, as in lime-burning, glass-making, the reduction of iron, &c.

Sulphuric acid and lime form sulphate of lime (CaO, SO_3), frequently called gypsum, selenite, and plaster of Paris, on account of its being found in the neighbourhood of that city. It occurs largely in the mineral kingdom.

Sulphate of lime may be prepared artificially by several processes, as by mixing a solution of chloride of calcium or of nitrate of lime with one of sulphate of soda, or with dilute sulphuric acid. A bulky colourless precipitate is obtained when the solutions are moderately strong, which is sulphate of lime. This salt is nearly tasteless; it requires nearly 462 times its weight of boiling water for solution, and it is nearly as soluble in cold water. It is insoluble in alcohol. It is met with in most river and especially in spring waters, and, as before indicated, is one of the salts which imparts to them the property called hardness. The air has no effect upon it; the artificial as well as the natural crystals contain water, and the salt is composed of

1	Equivalent of sulphuric acid	=	40
1	lime	=	28
2	water	=	18

Equivalent = 86

When heated, the water is expelled, but it has a great disposition to regain this water, and when it is made into a paste with water it becomes warm, and then a solid uniform mass in a few minutes. It is upon this property of losing water by heat and recombining with it by admixture with a small quantity that its use in taking casts, &c., depends. When sulphate of lime is exposed to a violent heat it melts, and yields an opaque vitreous globule. Sulphate of lime is not only used for taking casts, but occasionally as manure, or rather, probably, as a corrective of certain soils.

Sulphite of lime ($\text{CaO}, \text{SO}_2 + 2 \text{Aq.}$). Hydrate of lime absorbs sulphurous acid with facility; the compound forms a convenient source of sulphurous acid.

Oxalic acid and lime form oxalate of lime ($\text{CaO}, \text{C}_2\text{O}_3$). This salt exists in the form of calculi, and also in certain plants. It is readily procured by adding either oxalic acid, or, which is better, oxalate of ammonia, to a solution of a salt of lime. It is a white, extremely insoluble substance; it is dissolved by acids, except acetic acid, and decomposed at a high temperature, and converted first into carbonate and afterwards into pure lime. Oxalic acid and lime form so insoluble a compound, that they are used as tests of each other's presence.

Phosphoric acid and lime form several compounds, one of which occurs in nature. [APATITE.]

There are some other phosphates of lime; the ordinary triphosphate is prepared by adding a solution of phosphate of soda to one of chloride of calcium. A white powder, insoluble in water, but dissolved by acids, is precipitated. It is composed of

1	Equivalent of phosphoric acid	=	72
3	lime	=	84

Equivalent = 156

or ($3\text{CaO}, \text{PO}_3$). [BONE-EARTH.]

Three-fourths phosphate is obtained by mixing a solution of phosphate of lime in phosphoric acid with alcohol. It is a white substance, which reddens litmus paper on account of the excess of acid; this excess is removed by water, and then the neutral phosphate remains. It is composed of

3	Equivalents of phosphoric acid	=	216
4	lime	=	112

Equivalent = 328

Diphosphate of lime ($2\text{CaO}, \text{HO}, \text{PO}_3 + 4 \text{Aq.}$) occurs in irregular six-sided tables. It is soluble in solution of carbonic acid, and in this state is not unfrequently found in mineral waters. After heating to redness it contains

1	Equivalent of phosphoric acid	=	72
2	lime	=	56

Equivalent = 128

Superphosphate of lime is the name given to a mixture of crushed burnt bones, oil of vitriol, and water, allowed to stand for a few days in a warm situation. Mixed with earth, it is largely used as a manure for land.

	No. 1.	No. 2.
Burnt bones	2 parts	155
Sulphuric acid	1	100 to 150
Water	3	200

No. 2 is more soluble than No. 1.

Chlorine and lime act upon each other in a peculiar manner, which is not as yet perfectly understood. When hydrate of lime is exposed to the gas, it absorbs nearly one-third of its weight, and the resulting compound has been called a chloride and a hypochlorite of lime. Although its exact nature has not been determined, it is a most important compound, and is used to a great extent for the purposes of bleaching, being frequently called *bleaching powder*. In solution it is employed as a disinfectant.

The properties of lime-salts are the following: They are colourless if the acid contained in them is colourless. They have a lower specific gravity than baryta or strontia salts; in other respects they much resemble the salts of these bases. Their solutions yield no precipitates with sulphuretted hydrogen, sulphide of ammonium, or a dilute solution of a sulphate, such as sulphate of lime, but are precipitated by carbonate of ammonia in the presence of chloride of ammonium. A soluble oxalate (*e.g.*, oxalate of ammonia) is an exceedingly delicate test for lime, precipitating that base from the most dilute solutions in the form of a white solid, insoluble in acetic acid, but soluble in hydrochloric or nitric acid.

CALCULATING MACHINES. [MACHINES, CALCULATING.]

CALCULUS is the general term for inorganic concretions of various kinds, formed in various parts of the body, and bearing a general resemblance in shape or composition to stones. The particles of which they are composed are frequently arranged by peculiar chemical affinities into regular forms; and in these, as in other crystals, the process may begin around a fragment of some other substance, such as a clot of blood, a pellet of mucus, or some foreign body, lying loose in the fluid which holds the elements of the calculus in solution. They are also formed by the mechanical aggregation about a nucleus, or otherwise, of particles of different kinds accidentally thrown together, and cemented into a mass by glutinous animal matter: or, lastly, they may be the product of secretion; the more fluid part of the secreted matter being conveyed away or absorbed, while the sediment gradually thickens and hardens into consistence, adhering perhaps to some rough surface or projecting point, or being deposited in a hollow where the accumulation is least liable to be displaced by friction or washed away by the fresh influx of fluid.

Tartar of the Teeth.—The most familiar instance of the last-mentioned kind of concretion is that which is deposited from the saliva and mucus of the mouth between the teeth, and upon their outer surface next the cheek. This affection is not only productive of deformity, but of considerable injury to the teeth, which become loosened by the displacement and absorption of the gums under the increasing pressure of the mass. It may easily be prevented by a little attention in the use of the brush, or remedied by the operation of *scaling*, which gives no pain, and should never be postponed when it is necessary. The substance deposited is gritty, of a dirty yellow colour, and goes by the name of *tartar*, though it has no connection with the vegetable product so called. It is stated to consist of the phosphate and carbonate of lime.

Salivary Concretions.—Similar deposits, consisting nearly of the same materials, occur under the tongue or in the substance of the cheek in the ducts which convey the secretion of the salivary glands into the mouth. They sometimes attain a considerable size, and require an incision for their removal.

Pulmonary Concretions.—Hard irregular masses of phosphate of lime, rarely larger than an almond, are frequently met with in the lungs of consumptive patients. They are sometimes found imbedded in the pulmonary tissue, to which they adhere intimately; but more frequently in the middle of tubercular deposits, especially when these take place in the substance of the bronchial glands. They occasionally find their way by ulceration into the air-tubes, and are brought up by coughing.

Calcareous Concretions in the Blood-vessels and Heart.—Brittle earthy deposits, consisting chiefly of the phosphate of lime, are exceedingly common, especially in advanced life, in the arteries, and in the valves of the left side of the heart, the cavities of which contain arterial blood. They are formed at first in nodules or scales, behind the membrane which lines these parts internally, and sometimes accumulate to such an extent as to convert the arteries into rigid tubes, and to impede or even stop the motions of the heart. They are frequently the cause of *aneurism* and other serious diseases, particularly a kind of mortification of the extremities called *senile gangrene*, and that distressing complaint, *angina pectoris*, which is often found to arise from rigidity of the arteries which supply the heart itself with blood. These concretions are not, however, so often productive of mischief as might be expected; for scarcely an individual passes the middle period of life in whom this ossification of the arteries, as it is termed, does not exist in a greater or less degree. The veins are likewise subject, but much less frequently, to small corpuscular concretions called *phleboliths* (from $\phi\lambda\epsilon\psi$, a vein, and $\lambda\acute{\iota}\theta\omicron\varsigma$, a stone). They appear to be formed behind the thin lining membrane, which, as they grow, is pushed forward into the calibre of the vessel, inclosing them in a kind of capsule, and forming a narrow pedicle by which they remain adherent. After a time they become detached and movable. When they occur in the veins upon the surface of the body, they may be removed if troublesome; but they are not in general of any consequence, and are seldom larger than a very small pea. They are

quite white, and consist of carbonate and phosphate of lime, combined with much animal matter.

Calcareous deposits are also found occasionally imbedded in the muscles (where however they partake more than in other situations of the fibrous nature of bone), on the surface of the spleen and pleura, in the brain, and other organs, and in various morbid growths of a cancerous, scrofulous, or fungous nature; as well as round foreign substances of any description retained in the body, and subject to the action of its fluids. They do not admit of classification, but all consist of combinations of lime with carbonic or phosphoric acid, and animal matter.

Chalk-stones.—Gouty and rheumatic persons are subject to the deposition of a matter thus denominated, and resembling half-dried mortar, under the skin, about the joints chiefly of the fingers and toes. They have been met with in severe and long-continued rheumatism of the head beneath the skin which covers the cartilage of the ear. They frequently excite ulceration, and when they protrude externally may be removed; but an operation is rarely resorted to. They are found to consist of *urate of soda*.

Intestinal Calculi.—The bowels are sometimes obstructed by rounded masses, formed by the agglutination of dry fibrous particles, such for instance as the fine down or beard of the oat, which is not entirely removed by sifting the meal. These concretions usually form round a small piece of bone, a plum-stone, or other such body. They are smooth and compact in their structure, but of small specific gravity; the fibrous matter of which they consist occasionally alternates with concentric laminae of phosphate of lime, which usually forms a layer upon their surface. The circumstances which lead to their formation are obscure, but are possibly connected in some measure with constitutional predisposition, as they are found to recur habitually in the same person in spite of all precautions. The symptoms and most appropriate remedies for this complaint will readily suggest themselves; but its existence is in most cases rather suspected than ascertained till the calculus passes, as the symptoms may arise from other and very different causes of obstruction.

Gall-stones.—Calculi thus denominated are frequently found in the gall-bladder, or reservoir of the bile, which is attached to the liver, especially in persons who have reached the middle period of life, and have been long addicted to luxurious habits, or whose general health has been seriously impaired by mental distress or bodily ailment. They are often numerous, and one instance is recorded in which nearly three thousand were found at once. Generally, however, there are not more than three or four, and they are often solitary. They consist of one or more of the constituents of bile, with the occasional addition of phosphate of lime, and are white, or of shades intermediate between this colour, brownish yellow, and dark green. The white consist almost wholly of *cholesterine* (from *χολή*, bile, and *στερεός*, solid), a substance like spermaceti, first detected in the bile by Chevreul. The intermediate shades are composed of this substance, with more or less admixture of bile; and the darker kind seem to consist entirely of bile itself, inspissated. The last are rough and friable in their texture, sometimes much resembling cinders; the lighter varieties, on the contrary, are smooth and unctuous to the touch, presenting surfaces apparently flattened by mutual pressure. They are moreover distinctly crystalline, and sometimes lamellated, as if deposited in successive layers.

Biliary calculi are not productive of much inconvenience as long as they remain in the gall-bladder; but when they are protruded through the proper duct of that organ into the canal by which the bile passes from the liver into the intestine called the duodenum, they occasion great pain and disturbance of the health. The pain occurs in paroxysms, and is seated in the pit of the stomach, or a little lower and to the right, shooting to the back; and it is generally attended with vomiting and shivering, but not at first with a quickened pulse. If the bile be wholly obstructed, the evacuations lose their colour, and become unfrequent; the skin is tinged with a deep yellow, or *jaundiced*, as it is termed; rapid emaciation succeeds, with fever, and extreme debility and weakness. The event is sometimes fatal, but in general the stone passes at length into the duodenum, the flow of bile is re-established, and the disturbance subsides. The best remedies are emetics, aperients, *opium*, the warm bath and fomentations, and occasionally bleeding.

Urinary Calculi.—The urine is a very complex fluid, holding in solution at least twelve different ingredients in health, and more in disease. Some belong to the class of acids, as the uric, phosphoric, and oxalic; others are alkaline or earthy, as ammonia, soda, lime, and magnesia. In certain conditions of the system these elements are no longer kept in complete solution, but are precipitated or combined in a solid form, constituting various kinds of crystalline or sedimentary deposits, often arranged in successive layers; thus inducing those well-known affections, *gravel* and *stone in the bladder*.

Renal Calculus and Gravel.—Urinary concretions for the most part originate in the *pelvis* or hollow part of the kidney, either as small stones, or in the form of minute sand-like crystals. In this situation they are called *renal calculi* (from *ren*, the kidney). They may remain there permanently, and even attain a considerable size, so as to distend the cavity and cause absorption of the gland itself, without more inconvenience than an occasional sense of weight and a dull

aching in the loins. They may also produce inflammation and abscess of the kidney, which sometimes ends in the discharge of the stone with the other contents of the abscess through an ulcerated opening in the back; and sometimes in a lingering death. More commonly the deposit is carried with the urine, while yet of small size or in the form of sand, into the *ureter* or duct of the kidney, along which it descends more or less slowly into the bladder, with symptoms much resembling those which attend the passing of a gall-stone. These are shivering, sickness of the stomach, pain shooting in paroxysms from the back to the groin, and down the thigh of the same side; and, in males, retraction of the corresponding testicle. The circulation does not partake in the disturbance unless the calculus be so large as to obstruct the ureter, and thereby excite inflammation of the kidney. These symptoms constitute what is called *a fit of the gravel*, and generally terminate in the expulsion of the offending matter with the urine, which is not effected without much pain in the neck of the bladder and the urethra; the urine being voided in small quantities and with difficulty, and occasionally mixed with blood. The remedies employed in gall-stone afford relief in a fit of gravel. Copious draughts of some mild warm fluid should also be taken, with small doses of alkaline or other medicines, suited to the nature of the deposit.

Vesical Calculi.—It sometimes happens that a renal calculus, having reached the bladder in the manner described, is detained there, and becomes the nucleus of fresh concretions. Vesical calculus may also be formed upon a foreign body, such as the broken end of a catheter, or upon a small stone which has made its way inwards. Nuclei of this last kind are formed originally in the ducts of the prostate gland, which surrounds the male urethra just where it issues from the bladder, and consist of phosphate of lime.

In whatever way it may first arise, *vesical calculus* or *stone in the bladder* is one of the most dreadful maladies to which man is exposed. Even in its nascent state, but most certainly when it becomes at all large, the stone occasions excruciating pain. This is seated chiefly in the neck of the bladder where the stone usually rests, and, by sympathy, in the urethra near its external orifice: it is attributable, in a great measure, to the strong spasmodic contractions of the bladder upon the stone, and is most severe immediately after micturition. Hence, fortunately, it is intermitting; for when the bladder is full, the weight of the stone is partly sustained by the fluid, and it does not touch the sensitive internal membrane in so many points. In some cases the pain is more endurable than in others from peculiarity of constitution, or the comparative smoothness and lightness of the stone; but sooner or later the period of agony arrives; the bladder becomes intolerant of the smallest amount of distension, so that the urine is voided, as it enters, drop by drop, mingled with blood and mucus; and at length the patient inevitably dies, worn out by unremitted suffering.

There are remedies which are capable of affording a certain amount of relief for a time; but the only means that offer even a chance of a happier termination than death itself, are the removal of the cause by an operation. The stone must either be withdrawn through the urethra by a properly constructed instrument, which often succeeds when it is small in the male, and seldom fails in the female unless it be large; or it must be drilled and crushed into fragments small enough to be voided with the urine, according to a brilliant method of operating lately brought into notice [*LITHOTRITY*], or an incision must be made large enough to permit its extraction [*LITHOTOMY*]; a method practised by the ancients, and unfortunately by no means superseded (as some imagine) by lithotritry, which is out of the question in very young children, and often inapplicable in more advanced life. This disease is curable by the various means that have been devised, or a combination of them, in perhaps five or six out of seven cases, even in its advanced stage; and the average number of failures in young children does not amount to one in fourteen. It is always advisable that an operation should not be delayed when the existence of stone is proved, which, it may be observed, can only be done by actually striking it audibly with a metallic instrument called a *sound*; for not only is the stone constantly increasing in size, but the parts concerned may become incurably diseased in consequence of delay, or the general health may sink beyond the power of restoration. The idea of dissolving the calculus is a dream.

It is a curious fact in the history of this disease, that it is exceedingly common in some places and very rare in others. Thus at Norwich and Paisley together there are probably more cases in a year than in the whole of London; while at Hereford the disease is almost unknown. No researches into the cause of this difference have yet afforded a satisfactory explanation of it.

It would be tedious to enter at length into the chemical nature of urinary calculi. In weight they vary from a few grains even to several pounds, but seldom exceed a few ounces. They have been distinguished (chiefly by the labours of Dr. Wollaston) into the following kinds, which are here arranged nearly in the order of their frequency:—

1. Uric acid.
2. Oxalate of lime, called also the *mulberry calculus*, from its dark colour and rough surface.
3. Ammoniac-magnesian phosphate; called also the triple-phosphate.

4. Phosphate of lime, or bone earth calculus.
5. The fusible calculus, a combination of the last two species; so called from its fusibility under the blow-pipe.
6. The mixed calculus; composed of several of the other kinds confusedly mixed.
7. Urate of ammonia.
8. Carbonate of lime.
9. Cystic oxide.
10. Xanthic oxide.

The three last are extremely rare. The phosphatic varieties generally include a nucleus of the first or second species, and are found chiefly in advanced life, or in cases of long standing.

The substance called uric acid, of which probably three-fourths of the concretions in question consist wholly or in part, is sparingly soluble in water unless an alkali be present in a quantity more than sufficient to neutralise it; and from such a solution, of which healthy urine is an example, the addition of almost any other acid will precipitate either the urate of the alkali or the uric acid itself in the form of powder. To this peculiarity is probably due the formation of chalkstones—consisting, as we have seen, of urate of soda—in those who are subject to gout, as well as the proverbial liability of such persons to gravel and other calculous disorders; for in this complaint acetic acid is so abundantly generated as to be observable in the perspiration. Children also, in whom the food is so apt to turn sour upon the stomach, are much more liable to stone than the middle-aged, and their calculi almost invariably consist of uric acid. In such cases the alkalies and absorbent earths are of eminent service, by preventing the admixture of free acid in the urine, which is thus rendered more capable of retaining the urates in solution. These medicines, on the other hand, are extremely injurious if the phosphates happen to prevail, when acids should take their place, for reasons somewhat analogous. These considerations may have their use in pointing out the propriety of attending to the diet and the digestive functions, with a view to prevent or correct the formation of urinary concretions; and they no less forcibly illustrate the necessity of a knowledge of chemistry on the part of those who are intrusted with the treatment of such disorders, that the different kinds may be justly discriminated. This can only be done by a careful analysis of the urine and its sediments; a process which will be explained in the article on URINE.

Calculi in Inferior Animals.—*Biliary Calculi* are rare in the horse and the deer, for these animals have no gall-bladder, and the hepatic duct is large and straight, and the bile flows through it as fast as it is secreted. They are often found in the gall-bladder of the ox, sheep, and dog. There is scarcely a stall-fed ox slaughtered from Michaelmas to Lady-day in which they do not exist of large size or in great numbers; sometimes there is only one concretion, but that of considerable magnitude. In an ox that died of jaundice a gall-stone was found which weighed 15 oz. when first removed from the bladder. More frequently there are numerous calculi of a small size, scarcely larger than grains of sand, or many of them agglomerated together, forming a rounded or irregular body, from the size of a pin's head to that of a millet seed. More than 800 have been counted in the gall-bladder of one beast. Occasionally there is found an irregular crystallised body of a green or azure blue colour, glistening and polished. This forms a valuable pigment. The cause of these concretions is not well understood, but it depends greatly on want of exercise and impaired digestion. In the grass-fed ox they are seldom found. These calculi may exist in the gall-bladder without apparent injury to the health, but occasionally they press upon and close the passage through which the gall should be conveyed to the intestinal canal; or they enter into the hepatic duct and obstruct it, and prevent the flow of the bile through it; or, being numerous and large, they may by their presence and weight and friction irritate the mucous membrane of the cyst, and produce disease. [BILE, and DIGESTION, NAT. HIST. DIV.; JAUNDICE.] If the existence of inspissated bile, or biliary calculi, in the gall-bladder were indicated by a certain train of symptoms, the experience of the farmer would supply a ready and almost certain cure. The stall-fed ox has the gall-bladder partially filled with minute or larger concretions. The grass-fed beast in June will rarely furnish one. The former was idle and over-fed; the latter was compelled to exert himself a little in order to obtain his food, and he was kept under the salutary aperient influence of the newly-sprung grass.

Biliary calculi have been observed in the gall-bladder of almost every domestic quadruped, and very often in poultry. They differ materially in their composition, but agree in being crystallised bodies, formed of layer upon layer, and containing margaritic acid, animal mucus, a yellow colouring matter, and salts, principally phosphate of lime and magnesia.

Cerebral Calculi have been found more frequently in the horse than any other quadruped. They are contained in the ventricles of the cerebrum or the cerebellum, and attached to or enveloped by the plexus choroides. They are usually white, variously formed, of a stony hardness, and consist nearly of pure phosphate of lime. No peculiar symptom indicates the existence of the calculus, but the horse is suddenly attacked by inflammation of the brain and dies; upon examination the ventricles are found distended with fluid, and these concretions attached to the plexus of vessels. Afterwards, perhaps, it is recollected that the animal had been somewhat dull and stupid, sleepy,

and self-willed, and had frequently hung his head; that, in fact, there had been something wrong about the head. The irritation produced by the foreign body had been long existing and increasing.

Gastric Calculi are rarely or never found in the stomach of the horse; but they are of frequent occurrence in ruminants. Concretions varying from the weight of a few ounces to seven or eight pounds have been found in the paunch of cattle. There are traces of concentric layers in all of them, but they are far from being regular. There is usually some central nucleus, such as a small bit of nail or stone, around which has been collected a mass of earth and food and hair, cemented by the mucus of the stomach. When loose in the rumen, they acquire a globular form, but, having been confined in one of the compartments of that viscus, they are occasionally flattened, and in a few cases angular. The symptoms by which their presence is indicated are not well known, nor the effects which they produce; but one thing of some importance is certain, namely, that they are seldom found in healthy and thriving cattle. They may be either the cause or the consequence of disease, and much may be said on both sides. The method by which they may be dissolved or otherwise got rid of is unknown. A different kind of concretion is found in the abomasum or fourth stomach of cattle, and particularly of calves. It is composed almost entirely of hair, agglutinated by the mucus of the stomach. Cattle are frequently observed to spend a considerable time in the friendly office of licking each other: a portion of the hair mixed with the saliva is occasionally swallowed; and, not possessing sufficient solidity or weight to break through the roof of the paunch and enter that stomach, it passes along the cesophagean canal to the fourth stomach, where, by the peristaltic motion of that stomach, it is formed into a ball. There are no symptoms which clearly indicate the presence of these balls, nor is it plain by what means they could be expelled; but it is very evident that they have an injurious effect, producing distension of the paunch and loss of digestive power in the fourth stomach; the first by sympathy, and the latter by their direct presence. The animals in which these hair-balls are found after death were never well conditioned or healthy, and those that have expelled a hair-ball by stool have immediately begun to thrive.

Similar balls, but composed of felted wool, with portions of different kinds of food and various earthy and saline matters, mixed up with the mucus of the stomach, and having undergone a process of crystallisation, are found in the fourth stomach of the sheep, the goat, the chamois, the antelope, and the deer. They have usually a small nucleus, but the structure of the surrounding mass and the form of the whole admit of much variety. [BEZOARS.]

Intestinal Calculi are often found in the horse. They have almost invariably some central nucleus, as a seed, a small stone, or a bit of nail, around which particles of food and saline matters have accumulated and crystallised. They differ from the gastric calculi in the greater portion of earthy and saline matter of which they are composed, and scarcely a trace of food is detected in many of them. The concentric layers are well defined, and the ball, when dried, will bear a beautiful polish. They assume different forms, according to the portion of intestine which they occupy. In the colon they adapt themselves to the shape of the cells of that viscus, and represent a kind of four-sided prism; at the fundus, or base of the cæcum, they are globular. Twenty or thirty of the cells of the colon will sometimes be occupied by them, varying in weight from half an ounce to three-quarters of a pound. In the cæcum, a single concretion has occasionally weighed eight or ten pounds.

They are oftenest found in heavy horses of slow work. Mill-horses are also subject to them, and horses that are fed on much dry bran. The symptoms of their existence are obscure, and can scarcely be distinguished from those of colic. They have occasionally been expelled in the act of purging, but it would generally be a fruitless and a dangerous attempt to dislodge them, for they are embedded in the cells of the colon or the blind pouch of the cæcum. They destroy the horse by the irritation which they occasion, and by their weight, and especially in the concussion of rapid action they rupture the parietes of the intestine. It would seem almost incredible that they should remain so long as those of larger size must necessarily do. Many months or years must have passed away in the formation of a calculus that ultimately weighs eight pounds. There is scarcely a case in which they have occasioned the death of the animal, where careful inquiry will not elucidate the fact, that during a very long time the animal had experienced occasional attacks of apparent colic.

Salivary Calculi are oftener found in the herbivorous animal than in the human being, because there is a greater expenditure of saliva in mastication, and the salivary glands are larger and more susceptible of inflammation. They mostly exist in the parotid duct. They are of a dead-white colour, usually of an oblong form, of considerable density and specific gravity, and the surfaces highly polished or capable of being so. They are only injurious when they completely obstruct the duct: then the salivary fluid, continuing to be secreted, accumulates behind the calculus, and the canal becomes distended, and will burst, unless an incision is made upon the calculus, and the obstructing body removed.

The salivary calculus of the horse consists of 86 parts of carbonate of lime, 6 of animal matter, 4 of water, 3 of phosphate of lime and other salts, and 1 of mucous matter.

Urinary Calculi.—These, whether found in the kidneys, or ureters, or bladder, or urethra, have been observed in almost every domesticated animal. In the horse, a urinary calculus has occupied the whole cavity of the kidney and has weighed more than a pound. It has obstructed the ureters, and destroyed the horse and the ox: it has completely filled the bladder of the dog, and has been shivered into a thousand pieces by the sudden fall of the animal from a considerable height. In the urethra also it has been productive of fatal inflammation in the dog. In almost every animal sand has occasionally occupied the fundus of the bladder. Minute calculi have been found in almost countless numbers, or one large calculus has produced extreme pain, suppression of urine, and destructive inflammation. In most of these cases means have been found to allay to a certain degree the irritability of the bladder, but no medicine has the slightest solvent power on the calculus. The operation of lithotomy has been performed with success on almost every domesticated quadruped, and that of lithotripsy has been effectual in the horse.

Nearly the same constituent principles enter into the composition of these calculi in the herbivorous animals. The carbonate of lime prevails; there are, on an average, 83 parts out of 100 of it in the urinary calculus of the horse; 87 in that of the ox, and 91 in that of the ass; the remainder is made up of subphosphate of lime and animal cement. In the hog, however, ammoniacal phosphate of magnesia is, with the animal cement, nearly the sole material. In none of them has uric acid been detected.

The concretions which are found in other tissues and organs differ little from those in the human being.

CALCULUS, CALCULATION. The word *calculus* means a small pebble, such as was made use of in teaching or practising calculation. We must refer to articles of a more specific kind for different methods of calculation, but as regards this individual word, we have only to draw the distinction between it and *mathematics*. Generally speaking, a calculator is taken for a mathematician; which he may or may not be. Mathematicians are sometimes fond of and skilful in calculation, and sometimes the reverse of both: Euler and Wallis are instances of the former; Lagrange, according to report, of the latter. To perform a calculation is to put numbers together by rules, the reasons of which may or may not be understood by him who uses them. It is true that a mathematician must, in the process by which he becomes such, increase his power of calculation; but whether he will ever attain the expertness and correctness of a banker's clerk in the commonest operation, depends upon qualities of mind which have little or nothing to do with his *mathematical* power. It is necessary to caution our readers not to take a result as *mathematically* correct, because it is produced by a skilful calculator; or as *numerically* correct, because it has been worked by a good mathematician. The method of the first, and the work of the second, may be wrong, without any inference against either in relation to his peculiar pursuit.

The term *calculus* is commonly applied to signify any branch of mathematics which may involve or lead to calculation: any, in fact, except pure geometry. Thus, the part of algebra which relates to exponents and logarithms is sometimes called the exponential *calculus*. The references immediately following are to those branches which, without any particular reason, have permanently acquired the name of *calculi*. And, the word being now completely introduced, every new specific development of any part of mathematics will receive the name. Thus, the calculus of definite integrals, the calculus of discontinuous functions, &c., are terms which are beginning to be used. In fact, a *calculus* may now be defined as any method in which questions are treated in classes by general rules.

CALCULUS, DIFFERENTIAL. [DIFFERENTIAL CALCULUS.]

CALCULUS OF VARIATIONS. [VARIATIONS, CALCULUS OF.]

CALDARIUM. [BATH.]

CALENDAR. [CALENDAR.]

CALENDERING is a general name applied to the processes of smoothing, dressing, and glazing webs or textile fabrics of cotton and linen, either to prepare them for the operations of the calico-printer, or to impart the last finish to the goods before they are folded and packed for the market.

The common domestic smoothing-iron affords the simplest illustration of the process of calendering. The mangle, which is so frequently employed as a substitute for the smoothing-iron, presents another form, the operation of which is identical with that of some of the earlier calendering machines. In the common mangle, as in the old calenders constructed on the same principle, the cloths to be smoothed are coiled upon smooth wooden rollers, and laid between two hard flat surfaces. The lower surface is immovable, but the upper, which is formed by the bottom of a large heavy box, is capable of being moved backwards and forwards in the direction of its length, thereby causing the cloth-covered rollers to roll backwards and forwards until every part of the cloth wrapped upon them has received sufficient compression. In a common mangle the alternate motion of the pressing-box, which is usually loaded with stones, is produced by turning a winch-handle, which alternately winds and unwinds ropes extending from the ends of the box to a drum or cylinder fixed over it. To obviate the inconvenience occasioned by the frequent changes in the

direction of the motion required, various ingenious devices have been resorted to, by which the alternating motion of the loaded box is produced by a continued motion of the winch-handle in one direction. Being larger and heavier than common mangles, the old calenders made on the same principle were often worked by a horse-wheel, or some other moving power. The process of calendering was greatly improved by the invention of a machine in which the pressure is produced between cylinders, instead of between cylinders and flat surfaces, and in which, consequently, the alternating motion is got rid of; it is easier, too, by such a method to give a uniform and equal pressure. According to some authorities the cylindrical calendering engine was introduced into this country from Flanders and Holland by the Huguenots, who were driven to England by persecution. The rollers or cylinders were formerly made of wood; but, as it was found impossible to overcome the tendency of that material to warp and crack, they are now usually made either of paper or of cast-iron. The paper cylinders, which form the most remarkable feature of a modern calender, are formed in the following manner. The axis is a strong square bar of wrought-iron, and the body of the cylinder consists of a great number of circular pieces of stout pasteboard, each of which has a square hole in the centre to receive the axis, and six smaller round holes at equal distances from each other, near the periphery. A strong cast-iron plate, of a circular form, but rather smaller than the pieces of pasteboard, and perforated in like manner, is first put upon the axis, and then a sufficient number of pieces of pasteboard to form, when compressed, a cylinder of the required length. Another cast-iron plate is then added, and long cylindrical bolts of wrought iron, each of which has a head at one end, and a screw cut upon the other, are put into the six holes near the rim, and passed completely through the mass of pieces of pasteboard and the end plates of cast-iron. Nuts being put upon the ends of these bolts, the whole is screwed up as tight as possible, after which the cylinder is exposed to a strong heat for several days in a stove or heated chamber. By this process the pasteboard is considerably shrunk, and while it remains hot the nuts are repeatedly tightened up as much as possible. When allowed to cool the pasteboard is inclined to expand again, while the iron bolts contract, so that the mass of paper of which the cylinder is composed becomes almost inconceivably hard and dense. It is finished by very careful turning in a lathe, by which the surface of the cylinder is rendered perfectly true, and receives, in consequence of its extreme compactness, a very high polish. Iron cylinders, which are used in conjunction with paper cylinders in the same machine, are made hollow, and, for cases in which the application of heat is required, are constructed either to receive red-hot rollers or heaters, or to admit steam through a stuffing-box in the axis at one end, and discharge it at the opposite extremity.

The calenders now commonly employed for smoothing cotton and linen goods, contain four or five rollers, mounted above one another in a strong frame-work of cast-iron, which, from its ability to bear the application of heat without warping, is preferable to wood. If the object be simply to smooth the fabrics, the motion of the rollers, which can be made to bear against one another with any required degree of pressure by means of weighted levers, is so adjusted that, though their relative diameters may vary, their surfaces travel with equal velocity, so that no rubbing contact is produced. For some goods, however, especially those intended for use in household furniture, and in certain articles of dress, a glazed or polished surface, as well as mere smoothness or evenness, is required. Such goods were formerly glazed by hand upon an inclined table, with a rounded piece of polished flint attached to an apparatus which enabled the operator to preserve the cloth at a proper degree of tension, and to rub the flint backwards and forwards with considerable force over the surface, a small portion at a time. This process is now far more expeditiously performed with a calender of the ordinary construction, with the addition of a series of toothed wheels which cause the rollers to move with different velocities, so that the surface of one will rub or slide upon the surface of that adjacent to it. By the ordinary process of calendering, and still more by the use of the glazing calender, the round threads of which the web is composed are flattened, so that, by the diminution of the interstices, the fabric is made to appear closer than when it leaves the loom. Lawns, muslins, and other very light transparent fabrics are calendered with a very slight pressure, in a machine often worked by hand, which has the effect of smoothing the goods without altering the cylindrical form of the threads. The watered or "chine" goods exhibit in a remarkable way the effect produced by a partial glazing, or by imparting to the round threads a partial flattening in different directions.

When the operation of the calender is intended to finish goods for the market, it is immediately followed by folding and packing. The late Dr. Ure described a very complete calendering apparatus in use among the calico-printers of Alsace, to which a self-acting folder may be attached at pleasure. In the large establishments of Lancashire, the cotton goods are subject to immense pressure in a hydrostatic press, by the aid of which they are frequently made up into bales with such compactness as to occupy one-third less space than they could do if packed by hand in boxes. The calendering of goods in the process of manufacture is closely connected with the operations of the bleacher and calico-printer; but the calendering of finished goods is usually performed by the packer.

The process of calendering being comparatively simple, it has not undergone so many improvements within the last few years as other departments of the cotton manufacture. The change is mostly in the vastness of the operations. Manchester being the great market for Lancashire, in all that concerns the cotton trade, the calendering and packing are conducted on a stupendous scale in that city,—not only hydraulic machines being employed to give the pressure, but also steam-engines to work those machines.

It is not possible to state the extent of this trade; for it is optional to a manufacturer to determine which of his goods shall undergo a regular process of calendering.

CALENDS. [KALENDS.]

CALENDULIN. A mucilaginous matter of unknown composition, found in the leaves and flowers of the *Calendula officinalis*.

CALF. [COW.]

CALICO. [COTTON.]

CALICO-PRINTING, the art of dyeing woven fabrics of cotton with variegated figures and colours more or less permanent. It has been practised from time immemorial in India, upon the kind of cotton cloth called calico, which is supposed to have derived its name from the town of Calicut.

History.—There are very few dye-stuffs capable by themselves of imparting to cotton colours of sufficient lustre and durability combined. They must in general be rendered fast as well as brilliant, by the intervention of certain substances, which, in consequence of their attraction for the textile filaments and the colouring matters, form a bond of union between the two, and are on that account sometimes called *bases*, and at other times *mordants*. The last-named substances are so called from their taking firm hold of, or biting, the dyes. These intermediate bodies, though colourless themselves, generally possess the power of modifying more or less the colour of the dye, or of producing from the same dye-stuff different tints; so that a piece of white cloth, after being imbued with various mordants, will assume various colours in a single dye-vat. Thus if white calico be impressed with the mordant of acetate of alumina in one set of lines, with that of acetate of iron in a second, and with a mixture of these two mordants in a third, on being exposed to a solution of madder-dye for a proper time, it will become permanently printed in red, black, and chocolate stripes.

Although this scientific chemical process would seem to be characteristic of the refinement of the present time, yet it was known to the ancient Hindus and Egyptians. Pliny describes it with sufficient precision. "Robes and white veils are painted in Egypt," says he, "in a wonderful way; being first imbued, not with dyes, but with dye-absorbing drugs, by which they appear to be unaltered, but when plunged for a little in a cauldron of the boiling dye-stuff, they are found to be painted. Since there is only one colour in the cauldron, it is marvellous to see many colours imparted to the robe, in consequence of the modifying agency of the excipient drug. Nor can the dye be washed out. Thus the cauldron, which would of itself undoubtedly confuse the colours of cloths previously dyed, is made to impart several dyes from a single one, painting while it boils."*

In India, where manufacturing processes have probably suffered little change in the course of three thousand years, not only is the art of using mordants well known, but that of applying resist pastes, in order to preserve the cloth from the action of the dye-bath in any desired figures or spots. In the Société Industrielle of Mulhausen, a town of great celebrity in calico-printing, may be seen specimens not only of modern Indian calicoes in the preparation state, topically covered with wax, to serve as a resist to the indigo dye, but of ancient styles of pencilled cloths, which had been the work of princesses, covered with figures of such complexity as could not be made without a very tedious and costly education, beyond the reach of ordinary artisans. Among other curiosities, the counterpane of a state bed is shown, six yards long and three broad, which must have taken a lifetime to execute, on their plan of applying the melted wax with a pencil. How far this differs from the peculiar mode of producing Indian handkerchiefs, may be seen under BANDANNAS.

Processes of printing, similar to the Indian, have been long practised in Asia Minor and in the Levant; but they were not attempted in Europe till about the middle of the 17th century, when extended commerce had made the brilliant colours of the eastern world objects of general admiration and desire. Anderson, in his 'History of Commerce,' places the origin of English calico-printing as far back as the year 1676; but Mr. Thomson, of Primrose, near Clitheroe, a better authority, assigns the year 1696 as the date of the commencement of this art in England, when a small print-ground was established on the banks of the Thames, at Richmond, by a Frenchman. The first large establishment of the kind was at Bromley-hall, in Essex. It was not till the year 1768, however, that the business was carried into Lancashire, where it now constitutes one of the most interesting and productive branches of English manufacture. From its outset, the printing of cotton goods encountered the keenest hostility from the silk weavers of Spitalfields, who in the year 1680, and often afterwards, assailed in a riotous manner the East India House, on account of the Company importing the chintzes of Malabar. The English government

gave way to the remonstrances of the silk trade, and imposed, first of all, heavy duties on Indian calicoes, and in 1700 prohibited their importation altogether. This law became nearly inoperative, in consequence of the excessive penalties annexed to its infraction. So little were the principles of free commerce understood, that in 1720 the wear of all printed calicoes whatsoever, foreign and British, was prohibited by a new law, passed for the purpose of allaying the clamour of the woollen and silk manufacturers; but in 1730 parliament was pleased to permit British calicoes only, made of cotton weft and linen warp, to be printed and worn, on paying a duty of 6d. the square yard. It was not till 1774, and after a most expensive application to parliament, that cloth made entirely of cotton was allowed to be printed; in spite of the manifest fact that cotton cloth was far better adapted to the purpose than the mixed webs of linen and cotton, which took the colours unequally, owing to the unequal attraction of these two fabrics for dyes. The calico-printing of this country continued to groan under the most oppressive fiscal laws till the year 1831, when they were finally repealed, and the business was left to its natural rate of development, under the taste, science, and capital of the country. Since that time it has increased to a prodigious extent.

Linen was long ago, and silk and woollen fabrics more recently, made the subjects of topical dyeing, upon principles analogous to those of calico-printing, but with certain peculiarities, arising from the nature of their textile materials.

Processes.—Calicoes, muslins, &c., intended for printing must be first of all freed from their fibrous down; which is effected by the action of the singeing machine. This consists either of a semi-cylinder of cast-iron laid horizontally, and kept at a bright red heat by a furnace, or of a horizontal range of gas-jet flames: over one of these the plane of cloth is drawn with a steady continuous motion, and at a rate suited to its texture. When gas-flames are employed, a line of suction-tubes is placed over the extended web, to draw the flame up through the interstices of the cloth, which effectually clears the threads from the loose fibres. Some manufacturers singe the goods as they come from the loom; but it is generally deemed preferable to previously wash out the weaver's dressing at the dash-wheel, and then dry and calender the woven fabric.

The cotton cloth, after the singeing, must be next well bleached, because the whiter it is the more light will it reflect from its surface, and the more brilliant will be the colour of its dyes. The first step in the bleaching process is that of boiling the cloth in an alkaline bath, which for delicate fine goods consists of a weak solution of soda, and for stronger articles slaked lime and water. For this purpose a bowking apparatus merits the preference. It consists of a large egg-shaped cauldron, with a flat false bottom placed a little above the rounded true one, to protect the cloth from the danger of being scorched by the fire. Through the centre of the false bottom a vertical pipe rises from near the real bottom to somewhat higher than the top of the cauldron, and carries a conical cap (umbrella-wise) above its open mouth. The boiler being filled with goods, and supplied with a proper quantity of the detergent liquid, is securely covered with a dome-shaped lid. Whenever ebullition becomes active, the steam forces a continuous stream of liquid up the central pipe, causing its overflow, whereby the goods are irrigated and soaked with the boiling hot ley of lime, soda, or potash. During its descent it is partially cooled, but on reaching the bottom it recovers its ascensional power by the agency of the steam, and thus circulates up and down as long as the heat is maintained. The cauldron having been allowed to cool a little, the goods are removed, and subjected either to the rinsing operation of the dash-wheel, or to the proper rinsing machine. This consists of a range of wooden rollers in pairs, each lying upon its fellow, mounted in a horizontal plane upon the top edges of an oblong wooden cistern filled with water, with single roller-pins at the bottom of the cistern, in correspondence with the top ones. The beginning of a series of webs stitched together at the ends being introduced between the roller-pins above and round the roller-pins below, the last or traction roller is placed in connection with the moving power, while a stream of pure water is made to flow through the cistern; the cloth is thereby alternately squeezed between the top rollers and immersed in the water, so as to get effectually rinsed with hardly any manual labour. In some calico print-works, this rinsing apparatus occupies a length of 40 or 50 feet. The goods are next steeped for a few hours in a leaden or wooden cistern, containing a weak solution of chloride of lime. They are once more rinsed. They are now boiled in an alkaline ley, made of crude soda dissolved in water, and freed from its impurities by filtration or subsidence. The goods are again rinsed, and finished by a steep in sulphuric acid very largely diluted with water; this removes any adhering particles of lime or iron, which would be apt to give the cloth, after some time, a yellow tint. They are last of all rinsed, dried, and sometimes smoothed under the calender. If they are not calendered, they are run through a machine called in Lancashire the *candroy*, which spreads them smoothly in the act of rolling them upon a cylinder.

The process of bleaching, here described, is adopted as a preliminary to calico-printing. The larger operations, for the production of white or unprinted goods, are noticed under BLEACHING.

The cloth is now supposed to be ready for the printing processes, which we proceed to describe,—first, in relation to the mechanical apparatus, and then to the chemical ingredients.

* Natural History, book xxxv. chap. ii.

There are four modes of printing calicoes and muslins. The first is by small wooden blocks worked by hand; the second by large wooden blocks, set in a frame, and worked by a machine called the *Perrotine* (from the name of its ingenious inventor, M. Perrot, of Rouen); the third, by flat copper plates (a method now nearly obsolete); and the fourth, by copper cylinders, mounted in a machine of great elegance and productive powers, called a one, two, three, four, &c., coloured calico-printing machine, according as it is mounted with one, two, three, four, or more cylinders. The last colour is generally applied by what is called a surface cylinder, covered with figures like types in bas-relief.

The blocks for the first of these four methods are made of sycamore wood, or of deal faced with sycamore. They are about ten inches long and five broad, with an arched handle on the back. The face is either cut in relief into the design required, or the same object is obtained by the insertion edgewise into the wood of narrow slips of flattened copper wire, in the desired configurations. These narrow fillets have one edge inserted into the wood, are fixed by the taps of a light hammer, and are filed down and polished into one horizontal plane, to secure equality of impression in the several lines. The interstices between the copper ridges are filled up with felt-stuff. Occasionally both the wood-cutting and insertion plan are combined in one block.

Calico-printing by hand is performed by applying the face of the block to a piece of woollen cloth stretched over one end of a sieve-hoop, and imbued with the colouring matter of a thin pasty consistence by means of a flat brush. The block is then applied to the surface of the cotton cloth while extended upon a flat table covered with a blanket, and the impression is transferred to it by striking the back of the block with a light mallet. This method, besides the great cost of labour which it involves, has the inconvenience of causing many irregularities in the execution of the work. It has been superseded to a considerable extent, both in France and Belgium, by the *Perrotine*, a machine adverted to in a preceding paragraph. Three thin wooden blocks, engraved in relief, about three feet long and from two to five inches broad, are successively brought to bear on three of the four faces of a prismatic roller of iron, round which the cloth is successively wound. Each block rests on springs which enable it to press with the delicacy of a skilful arm; and each receives its proper-coloured pigment from a woollen surface imbued by a mechanical brush in rapid alternation. One man, with three children for superintending the three colours, can turn off about thirty pieces English in a day, which is the work of fully twenty men and twenty children in ordinary block-printing. To print a piece of cloth by hand the block must be applied 448 times for each colour. The machine, moreover, may be conducted by persons with little manual dexterity, and therefore entitled to comparatively low wages. The use of the *Perrotine* is spreading rapidly into every quarter of the continent, even into Russia. It executes a style of work different in some respects from that of the cylinder.

This latter machine, which is now the chief characteristic of English print-works, is a hollow cylinder of copper, fully three feet long, and three or four inches in diameter, whose surface is engraved with the required device. This engraving is effected, not by the hand-graver, but by the mechanical pressure of a steel roller from one to two inches in diameter and three inches long, which transfers the figures engraved on it to the relatively softer copper. The first steel roller, called the die, is softened before being engraved in intaglio; it is then hardened, and made, by a powerful press, to transfer its design in relief to a similar die called the mill, which is the one used for transferring the design to the copper cylinder. The process of etching is also sometimes had recourse to for covering the cylinder with various figures.

The engraved cylinders are mounted upon a strong iron shaft or arbor, carrying a toothed wheel at its end, in order to put it in train with the rotatory printing-machine, for one, two, or more colours. On a roller, at the upper part of this apparatus, are wound whole calico webs stitched together, the end of which is then introduced between the engraved copper cylinder and a large central cylinder covered with blanket, against which it is made to bear with regulated pressure. The engraved cylinder turns on the top of another cylinder covered with woollen cloth, which revolves with the former while its under part is plunged in an oblong trough containing the colouring matter in the state of a paste. The engraved cylinder is thus supplied with an abundance of impressible colour, and is cleared from the superfluity by the thin edge of a flat ruler made of bronze, called vulgarly the doctor (*doctor*), which is applied obliquely to it with a gentle force. The cylinder, after its escape from this wiping tool, acts upon the calico, and rolls it onwards with its revolution, imparting its figured design with great precision.

Three and four-colour machines are now made at Manchester of such excellence that they will print a piece of twenty-eight yards per minute, each of the three or four cylinders inserting its distinct colour or mordant into the pattern. At this rate the astonishing length of nearly one mile of well-coloured designs of exquisite beauty is printed in an hour. Such is the combined result of mechanical and chemical science, each of them brought to a high pitch of perfection. Cylinder-machines for six, eight, or ten colours are now made; but it is not general to exceed four or five cylinders.

Having thus noticed the mechanical arrangements for calico-printing, we must next speak of the substances employed as colouring agents.

Dye-stuffs, capable alone of imparting fast colours to calico, are conveniently called substantive; and such as require the intervention of a mordant, adjective. Indigo, catechu, and certain metallic oxides, belong to the former class; madder, cochineal, and Persian berries, to the latter. There are five general styles of work in calico-printing:—

1. The fast-colour or chintz style, in which the mordants are applied to the white cloth, and the colours of the design are afterwards developed in the dye-bath.

2. Where the whole surface receives a uniform tint from one colouring matter, and figures of other colours are afterwards brought up by chemical discharges and re-actions. This is called the Rongeant style in France.

3. Where the white surface is impressed with figures in a resist paste, and is afterwards subjected to a general dye, such as the indigo-vat.

4. Steam-colours, in which a mixture of the mordants and dye-extracts is applied to the cloth, and the chemical combination is effected by the agency of steam.

5. Spirit-colours, consisting of mixtures of dye-extracts with nitromuriate of tin. These cannot be exposed to a steam heat without corroding the cloth. This style is brilliant, but fugitive.

The nature and operation of mordants need to be well understood. There are only three bases which are of much importance as mordants—clay, iron, and tin. The first is commonly employed in the state called acetate of alumina; the second, acetate of iron; and the third, nitromuriate and oxymuriate, or perchloride, of tin. The clay mordant is prepared by the makers of wood-vinegar, who decompose alum by acetate of lime, both being in a state of solution; it is called red liquor because it is the mordant for reds in calico-printing. The iron mordant is made by exposing iron turnings to the action of crude vinegar. The tin mordants are prepared by the ordinary chemical means, which we need not here describe. For the most delicate purposes, the acetate of alumina is prepared according to the following French prescription:—

50 gallons of boiling water
50 pounds of alum
20 " of soda crystals
37½ " of acetate of lead.

The alum is to be dissolved by pouring the water upon it in a tub, and stirring with a rake; and the soda crystals are to be added gradually to that solution. When the effervescence is over, the acetate of lead, well pulverised, is to be strewed in at once, and stirred about till it disappears by decomposition. A deposit of sulphate of lead is formed at the bottom. Acetate of alumina, mixed with a certain portion of alum, is contained in the supernatant liquor. To form an acetate of alumina free from alum, 82 parts of acetate of lead, instead of 37½, should be employed for 50 of alum. About one-half of the alum therefore remains undecomposed in the above operation. For certain purposes a formula is prescribed in which 50 lbs. of acetate of lead are used to 50 of alum. The clay mordant is used also for particular styles in a state of combination with potash. It is prepared from a solution of 100 lbs. of potash and 80 lbs. of quick-lime with 100 gallons of water, boiled together for an hour. After the calcareous matter is settled, the clear liquor is to be drawn off and boiled down to specific gravity 1.320. In 30 gallons of this lye, 100 lbs. of pulverised alum are to be dissolved at a boiling heat. On cooling, crystals of sulphate of potash form. The supernatant liquors being decanted, and the crystals slightly washed with water, about 33 gallons of mordant will be obtained.

The tint or shade of colour produced in the dyeing-bath is proportional to the strength of the mordant previously applied to the cloth. Hence by diluting the mordant to various degrees any desired shade may be obtained—as by mixing the red liquor and the iron liquor any shade intermediate between red and black is producible in the madder-bath. When the iron liquor is diluted, various shades of violet result from the same dye. Too much of this aluminous mordant should not be prepared at a time, as it is injured by keeping, in consequence of its letting fall subsulphate of alumina.

The thickening of mordants is one of the most important operations in calico-printing; for the permanence and beauty of the impression depend not a little on the consistence and quality of the inspissating substance. Several circumstances require the consistence to be modified; such as the nature of the mordant, and its density or acidity. A strong and acidulous mordant does not thicken well with starch; it requires British gum or gum Senegal. Some other mordants inspissated by starch, which have a tendency to liquify after some days, are also liable to run during the printing; this inconvenience the French printers are accustomed to counteract by the addition of 2 oz. of alcohol to a gallon of the mixture—a remedy which cannot be economically practised in this country, owing to the excessively high duties on spirit of wine. The same mordant, when thickened in different degrees, gives different shades in the dyeing; for instance, one thickened with starch gives a deeper shade than when thickened with gum. Yet there are many cases where the latter merits a preference, because it imparts more transparency to the colours, whereas a portion of starch often remains in the cloth along with the mordant after the rinsing operation. In general, however,

to obtain a like consistence, much more gum is required than starch, and thus the former not only dilutes the mordant too much, but by letting it dry too quickly prevents its forming an intimate combination with the stuff. Hence the tints are thin and scratchy. The substances usually employed for thickening are the following: flour starch, flour, roasted starch, gum Senegal, gum tragacanth, salep, pipe-clay mixed with gum Senegal, sulphate of lead and gum, sugar, treacle, glue. It is found desirable, after thickening with gum, not to add any metallic salts in a liquid state, such as nitrate of iron, solutions of tin, copper, subacetate of lead, &c.; for they have the property of coagulating gum. The thickening material should, in fact, be skilfully adapted to each particular colour.

In the colour-house there ought to be ready prepared a variety of dye-decoctions, concentrated to a proper degree either by steam boilers, or by liquid baths of regulated temperature. When evaporated over a naked fire their tint is too often degenerated. The following prescription may serve as an example: Take 5 lbs. of Brazil wood or peach wood, boil it for an hour in 10 quarts of water, and strain; boil the residuum in the same quantity of water for half an hour, and again strain; finally boil it a third time, and mix the whole strained liquors together. Evaporate the whole till it is reduced to 10 quarts. Add as much red mordant (acetate of alumina or nitromuriate of tin) to the liquor as will brighten its tint to the desired degree, and thicken it with British gum. The older the decoction, the more beautiful will the colour be. The decoctions usually kept ready are those of logwood, Brazil wood, peach wood, Persian berries, quercitron, galls, fustic, archill, cochineal, ammoniacal cochineal, and catechu.

The printing shops ought to be kept always at a pretty high temperature, from 65° to 75° Fahrenheit; with an atmosphere rather humid than dry. It is often observed that goods printed the same day and with the same mordant exhibit inequalities in their tints; being sometimes strong and well brought out in one part, flat and meagre in another. The latter portion has been printed in too dry an atmosphere, an accident more liable to happen with cylinder goods than others on account of the small quantity of colouring matter which they receive. The nearer the mordant is to a neutral state, the less likely is this inconvenience to ensue. In the padding process, as it is called, where the cloth is uniformly imbued with the mordant, the stove-room, where a great many pieces are dried at the same time, ought to have a free issue for the watery and acetic acid exhalations. The goods ought likewise to be properly extended before they are dried; for without this precaution the acetic acid would accumulate in the folds, and prevent the base of the mordant from combining with the fibres of the cloth; the consequence would be white spots in all such places, which would render the print unsaleable. When a strongly acid mordant has been employed, too much pains cannot be bestowed in facilitating its escape from the hot flue through which the goods are drawn in the drying; for the acetic fumes are capable of affecting the surface to such a degree as to cause a white down to appear upon the cloth after it is dyed. Fans will be found very useful in such cases to blow away the acidulous vapours.

After these general remarks we proceed to describe the processes of each of the five styles of printing above enumerated; and as the whole operation furnishes one of the most striking and beautiful examples of the application of chemical science to the manufacturing arts, we shall endeavour to convey some idea of the chemical constitution of the substances employed, and of the relation which they bear to the fibres of the textile material.

First style.—Chintz or fast-colours. Much of the printing done in this way is called the madder style. The following topical colours belong to this head: 1. *Black.*—It consists of 2 quarts of iron liquor, sp. grav. 1.040, thickened with 4½ oz. of starch and 4½ of flour; the starch being first rubbed up with a little of the liquor, then mixed with the flour. The old liquor being added, the mixture must be boiled over a brisk fire to form the paste, care being taken meanwhile to stir, so as to prevent its being burned by sticking to the bottom. The colour is to be poured into an earthen pot, over half an ounce of olive oil, and the two are to be thoroughly incorporated. 2. *Red.*—Take 2 quarts of red liquor, at sp. grav. 1.033, 8 oz. of starch, and tinge with a little Brazil wood. Boil for five or six minutes, and pour into a pipkin, stirring all the while. Different shades of red are obtained by preparing mordants of different strengths from the above, thickened either with raw or roasted starch. 3. *Dark Puce.*—Take 1 quart of red liquor, and 1 quart of iron liquor; mix and thicken like black, No. 1. By varying the proportions of the two liquors any brown tint may be obtained. When British gum is employed to thicken reds, 1¼ lb. of it are required for every two quarts of the liquor; in which case no other tingeing substance is needed. 4. *Violets.*—Take 2 quarts of iron liquor of sp. grav. 1.007, thicken with starch, and tinge with a little logwood. These four mordants, for four colours, are sometimes applied at once; but where brilliant reds and rose-colours are wanted, the dark colours must be inserted separately, after the bright ones are raised, by a subsequent process called grounding (filling up the ground of the figures) in this country, and *rentrures* (re-entering additional colours) in France.

The cotton goods, after having been printed with one or other of these mordants, either by the block or the cylinder method, must be

hung up in a warm chamber for thirty-six hours at least before having their colours brought up in the dye-house.

The dyeing may be divided into four operations. 1. The dunging; 2. the maddering; 3. clearing the madder-grounds; 4. grounding with topical dyes.

1. The dunging is undoubtedly one of the most important though mysterious processes in calico-printing; and too much pains cannot be bestowed upon it, since it determines in a great measure the success of the madder-dyes. Its objects are to effect the complete combination of the subsalts with the cloth, and to separate the acetic acid which had not been dissipated in the stove-room; to dissolve and separate from the cloth a portion of the substances used for the thickening, and to wash away at the same time the mordants mechanically retained by the paste; and lastly, to prevent the uncombined parts of the mordants, as well as the acetic acid, with which the bath becomes eventually charged, from re-acting upon the part of the mordant combined with the cloth, or from attaching itself to the white ground. Cow-dung, the kind employed, affords to chemical analysis the following constituents: an animalised fibrous substance, to the amount of ten per cent.; albumen; animal mucus; a substance resembling bile; several salts, of which the principal are muriate of soda and of ammonia, acetate of ammonia, and phosphate of lime; benzoin, or musk, which gives it a peculiar flavour. Among all these ingredients the fibrous matter plays the principal part in the dunging of prints, from its great affinity for the alumina and the oxide of iron; it seizes them the moment they are diffused in the bath, and thereby prevents their being deposited upon the parts of the cloth which should remain white. The chalk occasionally added to the dung bath serves to neutralise the acids as they are evolved from the mordants; a little carbonate of soda is used in preference by some printers. For delicate pinks, pale yellows, and cochineal lilacs, a bran-bath answers better than one of dung. The dung-bath cistern is usually made of an oblong rectangular form, three or four feet wide, four or five feet deep, and twelve or fifteen feet long. Cast iron is usually employed for the cisterns in this country, and wood on the continent. It has one range of rollers level with the surface of the liquor, and another range near the bottom, over and under which rollers the expanded cloth is slowly passed in a serpentine course, so as to ensure the thorough operation of the liquid upon it. The rollers revolve by mechanical power, the extreme one being double, and placed above the cistern like a calender to draw the cloth (which is in webs stitched together) continuously through the baths by means of a cord tied to its end. One pail of dung is diffused through fifty or sixty pails of water. The bath must be replenished with dung from time to time, as it gets exhausted by the passage of the mordanted goods. The temperature of the bath should be maintained at about 150° Fahr. by means of a steam-pipe entering at the bottom. The duration of dunging is different for different goods, from fifteen to twenty minutes being the average time, which is regulated by the speed of the discharging calender rollers. Too high a temperature and too much dung are injurious to delicate colours, such as the pinks and the yellows; but colours thickened with starch require a higher temperature than those thickened with gum. The piece should never be allowed to stop for a moment in its progress through the bath; for the part in contact with the surface of the water would run, and cause a line mark across the cloth.

The goods must be washed in the dash-wheel, or run through a rinsing trough, and then winched through a fresh dung-cistern (commonly called a dung-copper) at a lower degree of heat than the former, and then washed again.

2. Next comes the maddering process. Madder always contains a free acid, which is more abundant in some species of the root than in others; that grown in calcareous soils often contains so much chalk as to be sufficient for neutralising the acid in the bath. The other species requires the addition of a little chalk or carbonate of soda; but care must be taken not to add an excess, for that would degrade the colour. Madder is the only dye-stuff which can saturate mordants so completely as to permit the goods to be subjected to other dyeing-baths, such as yellows, olives, &c., without losing its brilliancy by these fresh operations. Black, red, and chocolate are dyed with madder and sumach, but purple with madder alone. Different quantities of madder are used, according to circumstances, from 1 lb. to 3½ lbs. per piece of twenty-one yards; the sumach being one-eighth of the madder. The goods are entered into the automatic-reel bath when the copper is cool, the heat being brought up by slow degrees by means of internal steam-pipes, or an external fire, during the course of two or three hours, till ebullition begins. The boiling is continued sometimes for a quarter of an hour. The goods are all the time kept in a state of constant motion, down through the liquid bath on one side, up through the air and incumbent steam, and down into the bath through the other side, there being an open frame of wooden spars between them and the two sides of the copper. They are then washed and boiled in bran and water for ten or fifteen minutes; indeed if they have much white they must be branned a second time or even a third time, to clear the ground, and must be washed between each branning operation. The whitening is completed by spreading the goods upon the grass for a few days, or by passing them over a self-acting winch-reel, through a weak solution of chloride of lime. For strong reds a second maddering is sometimes given. In all these dyeing operations

too great a length of cloth should never be winched over one reel, for it would be left too long in the bath, and might get spotted or stained. The modern automatic coppers are of an oblong shape, semi-cylindrical at bottom; and the revolving axis which runs along their top is mounted with eight or ten reels, each of which winches only a few pieces tacked together into an endless web.

3. Clearing the madder-ground. Reds and pinks are brightened by being winched for half an hour through a soap-bath, at 150° Fahr., containing three-quarters of a pound per piece. They are then washed in clear water. At other times they are passed for a quarter of an hour through a bath containing a little of the solution of nitromuriate of tin; and are then soaped and rinsed, and laid out upon the grass; or cleared, as in France for fine colours, with a weak solution of chloride of soda.

4. Grounding with topical dyes. The grounding colours, or topical dyes, employed after the madding, are chiefly blues; one, called pencil blue, may be thus made. To 2 quarts of water heated to 145° Fahr. put 8 oz. of indigo, 8 oz. of orpiment, each in powder, and 8 oz. of quicklime. Heat the mixture up to the boiling point; withdraw the vessel from the fire, and when its contents are lukewarm, add 6 oz. of subcarbonate of soda (dry); stir the whole ingredients well together, and let them settle for twenty-four hours. The clear liquor being decanted off, is to be thickened with one pound of gum for each two quarts of it in measure. This colour was formerly introduced by the pencil, and hence the name usually given to it; it is now applied by one of the rollers of the calico-printing press. Twenty-four hours after receiving this impression, the cloth must be rinsed in running water. Another pencil-blue may be made as follows:—Take 2 quarts of caustic soda-lye, sp. grav. 1.160, heated to 145° Fahr., add 12 oz. of hydrate of protoxide of tin, and 8 oz. of ground indigo; heat the mixture till it boils, removing or applying the heat twice or thrice. Lastly, let it cool, and thicken with 3 lbs. of raw sugar. The application of this colour requires very nice management. Dry fine sand is sometimes dusted over the piece as soon as it is printed, to prevent the colour from running. If these blues be not skilfully and rapidly introduced, the tints are liable to differ in different parts of the cloth. An excellent blue for printing with the cylinder is thus made:—14 quarts of caustic-lye are mixed with 3½ lbs. of indigo and 5 lbs. of hydrate of protoxide of tin. Boil the mixture for ten minutes; take it off the fire; add 3 lbs. of Venice turpentine, and then thicken with 11 lbs. of pulverised gum. Print on this colour; let it dry for two days; wash in the dash-wheel; and pass the goods through a soap-bath, containing a little soda to brighten the blue, and take off its grey tint. The turpentine serves to obstruct the contact of air in the pot with the deoxidised indigo, which would spoil it as a dye before application. To produce a topical Prussian blue dye, the following directions are given:—Diffuse through 2 quarts of water 8 oz. of starch; boil, and pour into a pipkin. Take 2½ oz. of Prussian blue, grind it up with 3 oz. of muriatic acid, and after twenty-four hours dilute with 2 oz. of water. Mix this preparation with the above starch-paste while it is warm. When the mixture is cold, add to it 4 oz. of oxymuriate of tin, and pass the whole through a sieve. Goods grounded with this colour must be passed merely through the rinsing trough. Although blue is the principal, it is not the only grounding topical dye. Topical yellows are prepared from Persian berries, quercitron, and bi-chromate of potash; orange from the sub-chromate of lead; green from nitrate of lead, bi-chromate of potash, Prussian blue, and nitrate of zinc.

For bark-yellows, the same mordant is used as for madder-reds. The piece, when slightly dunged, is winched in the quercitron-bath, heated gradually up to from 130° to 140° Fahr. during about an hour. A gold colour is given in the following way:—Dissolve 5 lbs. of sulphate of iron, and 1½ lb. of acetate of lead, in a gallon of water; mix well, and after the precipitated sulphate of lead has subsided properly, decant the clear liquor, thicken it with gum, and apply the paste by the block or cylinder to the cloth; expose to the air for eight or ten days; and then winch it through a solution of potash thickened a little with lime. Whenever the black oxide of iron first precipitated upon the cloth begins to turn red, the piece must be removed into a rinsing cistern and well washed. Yellows are however now given very generally with chrome. For this purpose the following prescription will serve:—Thicken 2 quarts of water with 6 oz. of starch, pour the paste into a pipkin and add to it immediately 4 oz. of acetate of lead, and 4 oz. of nitrate of lead, both in powder; mix the ingredients well, and leave the mixture to settle and cool, colouring it with a few drops of solution of chromate of potash. Print on this paste with the cylinder or the block, and pass the goods through a roller dyeing-bath containing bi-chromate of potash dissolved in the proportion of 2 oz. per piece; having first charged the cistern with a solution containing half a pound in solution. Then pass them first between the rinsing-rollers, and finally through a very dilute muriatic acid to clear up the ground.

Green printing with chrome may be performed as follows:—Mix 2 quarts of caustic soda-lye at 1.160 sp. gr. with 3 oz. of ground indigo and 10 oz. of hydrated protoxide of tin. Heat the mixture to the boiling point, withdraw it from the fire, and when lukewarm add, by slow degrees, a solution of 1 lb. of acetate of lead in half

a pound of acetic acid of sp. grav. 1.050. When the effervescence ceases, thicken it with 20 oz. of gum and 20 oz. of roasted starch. Pass the mixture through a very fine sieve. After this paste is applied by the cylinder or block, the goods must be passed through milk of lime for ten minutes; then plunged for an hour in running water, and well rinsed. They must next be passed through a solution of bi-chromate of potash, then rinsed, and finally passed through weak acetic acid to clear the grounds. They may now be dried and prepared for the market. This colour requires for its perfection, that the goods be not passed through the bath in too dry a state, because the colour would be apt to scale off. Before passing them through the padding machine therefore, they should be hung up for an hour in a humid atmosphere.

Madder purple is obtained by the application of the acetate of iron mordant allowed to act upon the goods hung up in the air for six or eight days; and after dunging, and passing them through the madder-bath, then branning and clearing.

Cochineal pink is communicated by applying the aluminous mordant, with the precautions above prescribed, and raising the colour in a bath containing about an ounce of cochineal for every piece of cloth. Cochineal has a feeble affinity for cotton, and neither needs nor admits any other process for clearing the ground except simple washing in water.

Manganese brown is thus produced:—A solution of sulphate or muriate of manganese, properly thickened, being printed on, the calico is to be dried, and passed through a powerful caustic lye; from which it must drop into a solution of chloride of lime. The manganese is thereby raised to a higher state of oxidisation, in which it exercises a pretty strong affinity for cotton. In France a little tartaric acid is added to the solution of muriate of manganese before thickening it with gum, of which one pound and a-quarter are used for 2 quarts of the liquid, at a sp. gr. of 1.075.

Catechu brown, called carmelite by the French, is managed as follows:—In one gallon of water boil 1 lb. of powdered catechu till the liquor is reduced to half its bulk; pass it through a very fine sieve: dissolve in the filtered liquor 4 oz. of verdigris, and let the solution cool. Thicken with 5 oz. of starch, and while still tepid dissolve in it 5 oz. of powdered sal ammoniac. Print this dye on the goods, and after a few days pass through the rinsing apparatus.

Second style.—We now pass to the second style of calico-printing, the *Rougeant* style of the French; in which the whole surface of the cloth receives a uniform tint from one colouring matter; after which, figures of other colours are produced by chemical discharges and re-actions. The chemical action of the discharges must here be understood. Some of them are simple; some mordanted.

The elegant style of simple and mordanted discharges of Turkey red cloth was invented many years ago by MM. Kœchlin, of Mülhausen, and introduced into this country by Mr. Thomson, of Primrose, near Clitheroe. An excellent white discharge paste is made by the following prescription:—Dissolve in 2 quarts of water three-quarters of a pound of oxalic acid and 1½ lb. of tartaric acid, and add to the solution 2 quarts of lime juice concentrated to sp. gr. 1.230. Thicken with 6 lbs. of pipe-clay and 3 lbs. of gum. This is to be applied with the block or the cylinder-machine. The piece, after being dried, is passed through a bath containing a solution of chloride of lime. A cistern of wood, frequently lined either with zinc or lead, about five feet square and six feet deep, is furnished with a square wooden frame-work, bearing a series of parallel rollers in two ranges from top to bottom; which frame may be let down into the cistern, and lifted out at pleasure by the help of a pulley and counterpoised cord. The cistern is to be filled with a solution of chloride of lime, having a specific gravity of 1.040, and a proper decolouring force by the indigo test. Before entering the goods, the bath should be stirred up a little. The calico-pieces, stitched together lengthwise, are now by means of a guiding-cord led serpent-like over the respective rollers in horizontal planes, and are drawn through by a pair of squeezing-rollers at the opposite side to that where they entered. The cloth should be exposed to the action of the chloride liquor during a space of three minutes, by the equable motion of the drawing-rollers; and on its escape from them should be allowed to fall into a cistern of water, or be passed through the rinsing apparatus. Common madder reds and pinks are discharged in another way. The goods are passed through the acetate of alumina liquor in the trough of the padding-machine, called *foulard* by the French, whereby they are prepared for the madder-bath. They are dried, and then impressed with the discharge paste by means of the engraved block or cylinder. This paste consists of concentrated lime-juice properly thickened with pipe-clay and gum. Sometimes a little tartaric acid is added, or even bi-sulphate of potash, [for the sake of economy. This mordant is also sometimes applied before passing the cloth through the padding-machine; a practice supposed to produce the clearest whites, as the mordant in this case is never suffered to attach itself to the places intended to be white. If cloth so treated be subjected to dyeing in the madder-copper, its ground will come out red; if in the madder and logwood-copper, it will come out reddish brown; if in the cochineal, it will come out a beautiful pink; and in the logwood alone, a chocolate; with logwood and galls, black. If, after applying the above discharge paste by the block or cylinder, the

goods be padded with iron liquor or a mixture of iron and aluminous liquor, on dyeing them up in the madders, or other coppers, prints with various dark grounds will be obtained, enlivened by white figures. The best discharges upon manganese or bronze grounds consist of the acidulous nitromuriatic solution of tin, or salt of tin. To 2 quarts of water, made into a paste with 9 oz. of wheaten flour, add, when cold, from half a pound to a pound of muriate of tin crystals, according to the depth of the manganese tint to be discharged.

Compound discharges not only remove the mordant from the ground wherever they are applied, but introduce a new mordant upon the discharged points, so as to lay the foundation for these points receiving peculiar colours in the subsequent dyeing or padding operations. When mordanted goods are intended for the discharge process, they should not be much exposed to the air, as the mordant becomes thereby of too fixed a nature to be completely removed. Nor should they be washed out before the piece receives the discharge; for it ought to be kept in mind, that passing the goods through either the dung-bath or even chalk and water, tends to fix the mordant too firmly for the perfect action of the discharge. After receiving the discharge paste from the block or cylinder, the goods should be hung up in a cool place; for if suspended in a hot chamber the effect of the discharge will be impaired. After exposure for about twenty-four hours, more or less, according to the nature of the discharge, they must be subjected, at the rinsing-roller machine, to water heated to about 140° Fahr., and mixed with a little chalk or carbonate of soda, just enough to saturate the acidulous washings. They are then washed in cold water, next dunged, and finally dyed up in the proper copper.

A violet ground, with red and white figures, may be thus produced:—Pad with very weak iron liquor; dry moderately; print on the cloth with the one cylinder of the two-colour machine the red liquor mordant, properly acidulated with concentrated lime juice of specific gravity 1.240, and with the other cylinder the discharge-paste strengthened with tartaric and oxalic acids. After drying, rinse the goods through chalky water; dung, and dye in the madder-copper, and clear them as already prescribed.

To produce a gray ground with pink figures, the gray is first given with decoction of galls and nitrate of iron, applied the one after the other. The discharge paste is made by thickening 2 quarts of a strong decoction of Brazil wood or peach wood with 9 oz. of flour, and adding to the paste when cold 10 oz. of solution of tin, made by dissolving salt (muriate) of tin in twice its weight of muriatic acid.

To produce a chrome-yellow discharge upon a Turkey-red ground, take 2 quarts of lime-juice of specific gravity 1.09; dissolve in it 2 lbs. of tartaric acid, 2 lbs. of nitrate of lead; thicken with 2 lbs. of pipe-clay and 1½ lb. of gum, each previously pulverised. Tinge the mixture with a little chromate of potash, to indicate its nature. Most mordants are faintly coloured for that purpose. After applying this paste as above prescribed for the white discharge, pass the goods through the bath of chloride of lime, and rinse; then pad with bi-chromate of potash, which converts into a brilliant yellow all the figures to which the discharge-paste has been applied. For a green discharge upon Turkey-red ground; to the discharge for chrome-yellow add 12 oz. of Prussian blue colour, prepared by mixing 5 lbs. of Prussian blue in powder with 6 lbs. of muriatic acid, and diluting the mixture after twenty-four hours' digestion with 4 lbs. of water. Bi-chromate of potash may be employed as a discharge. After having dyed the goods in the indigo vat, they are to be padded in a bath of bi-chromate of potash, containing from 1 to 1½ oz. of the crystals per quart, according to the depth of blue to be discharged. Dry in the shade without heat, and print on the following discharge:—dissolve in 2 quarts of water 1 lb. of oxalic acid, 8 oz. of tartaric acid, and thicken the solution with 3 lbs. of pipe-clay and 1½ lb. of gum, adding to the whole 4 oz. of muriatic acid. After this paste is printed on, the goods must be rinsed through chalky water, heated to 145° Fahr., then washed in clear water and passed through very dilute sulphuric acid. The bi-chromate acts here a similar part to chloride of lime; for wherever the roller applies the acidulous paste there is an immediate white discharge, with the disengagement of a peculiar odour.

Third Style.—We now pass to that style of printing in which the white surface is impressed with figures in a resist paste, and is afterwards subjected to a general dye, such as that of the indigo-vat.

The name of resist paste is given in England, and that of reserve in France, to the substances which possess the property of counteracting the indigo-vat dye, in the spots to which they are applied to cloth. They have been divided into four classes: those of a fatty nature; those with a basis of metallic salts; the coloured reserves, capable of communicating different colours in the course of their application; and lastly, mordant reserves, which form the lapis lazuli style. The first are used only in silk-printing.

To prepare a white resist for deep blue, to be applied by the cylinder:—Dissolve in 3 quarts of water 1½ lb. of acetate of copper in crystals, and 5 lbs. of sulphate of copper, adding thereafter 3 lbs. of acetate of lead; thicken with 5 lbs. of gum, and add to the whole 5 lbs. of sulphate of lead. Print on with this paste; hang up for two days, and dip during two hours, by repeated immersions, in the blue-

vat. Finally, pass through very dilute sulphuric acid, to clear up the white figures. For a chrome-yellow resist:—Dissolve in 2 quarts of water 1½ lb. of nitrate of lead, half a pound of the acetate of copper; add to the solution one pint, or nearly so, of a saturated solution of subacetate of lead; thicken with 1½ lb. of gum and 3 lbs. of pipe-clay. Triturate the whole together, and pass through a sieve. After printing on this resist paste, the goods must be hung up for two days, and then dipped in the proper blue-vat. Steep the goods in water for half an hour, then rinse out slightly, and pass through a trough containing twelve pailsful of tepid water holding half a pound of soda crystals in solution. Turn over for a quarter of an hour, and rinse again. Now pass the goods for half an hour through a solution of bi-chromate of potash, containing 5 oz. for every piece; rinse; and, in order to separate the paste, pass through muriatic acid largely diluted with water, till the yellow hue comes fully out. Wash and dry.

In the lapis lazuli style, a resist for a full-bodied red is thus produced:—Dissolve in 2 quarts of red liquor, specific gravity 1.09, 2 oz. of corrosive sublimate, and thicken with 2 lbs. of pipe-clay and 1 lb. of gum, adding 4 oz. of olive oil. This and other coloured reserves are to be printed upon the cloth with the three or four-coloured calico-machine; four days thereafter give the pieces, at different periods of ten minutes each, successive dips in the blue-vat of the desired hue, with alternate exposure of them in the air also of ten minutes, according to the blue tint in demand. Rinse in a stream of water for half an hour. Into a copper nearly filled with water put two pailsful of bran; make the contents boil; then add cold water to lower the temperature to 180° Fahr. Enter the goods, and winch them during twenty minutes in the bran-liquor; remove and rinse them; pass them next through a trough containing sixteen gallons of water acidulated with three quarts of vinegar, and thereafter wash to prepare for the madding, which is to be done with the precautions already prescribed, taking care not to raise the heat of the madder-copper above 190° Fahr. The lapis style of goods must be finished with a bath of bran and exposure on the grass, twice or oftener alternated if necessary, to bring out the lustre of the colours. A little soap-water aids in the brightening.

Though China blues differ in their principle of application, they may be considered most conveniently under this head. The blue colour is prepared by grinding 16 lbs. of indigo, 3¼ lbs. of orpiment, 22 lbs. of copperas, with 5½ gallons of water, in the common indigo mill during three days. A part of this paste is to be thickened with strong gum-water in successive degrees of dilution, and a part of it preserved unmixed. Take three different shades of blue, the darkest being thickened with starch, and the pale with gum, and apply them by the cylinders of the three-colour machine. Hang up the pieces for two days in an airy place, not too dry, and then proceed to dip them as follows: three cisterns must be charged; the first with 300 lbs. of lime for 600 pails of water; the second with a solution of sulphate of iron (green copperas), at a density of 1.048; the third with a solution of caustic soda lye, at a density of 1.055, prepared from soda crystals and quicklime with water. The pieces being stretched on the frames, are to be dipped into the vat No. 1, and left there for ten minutes; they are then withdrawn, and allowed to drip during five minutes. They are now dipped in vat No. 2, for ten minutes, and taken out to drip for five minutes. After the last dip, the frame with the piece upon it must be immersed in a fourth vat, charged with sulphuric acid of specific gravity 1.027. The object of this immersion is to remove the oxide of iron deposited upon the surface of the cloth in its successive passages through the lime and copperas vats. It is next exposed for an hour to a stream of water, and finished by the action of a tepid bath of sulphuric acid, of specific gravity 1.027. The blues are afterwards enlivened by a feeble soap bath, at a heat of 145° Fahr. The theory of Chinese blues is one of the most beautiful developments of modern chemistry. The indigo and sulphate of iron imprinted at first on the cloth exercise no action upon each other till the cloth is plunged into the lime-water vat. Here a portion of the sulphate of iron is decomposed, and its protoxide is rendered free to de-oxidise the indigo, and to render it soluble in the lime-water. In this dissolved state its particles can penetrate the textile tissue, combine with its filaments, and on exposure to the air become a fixed insoluble blue. On dipping the cloth into the second copperas vat a new layer of oxide of iron is formed on the whole of its surface, which oxide operates only on the indigo spots, de-oxidising another portion of the indigo, which becoming soluble is removed at the second dip into the lime-vat. By these alternations, successive deposits of oxide of iron and sulphate of lime ensue, for the separation of which from the cloth the frame needs to be agitated in the lime-vat. In the copperas-vat, on the contrary, the frame should be kept motionless, to favour the deposition of as much oxide of iron as possible upon the indigo points. From these circumstances we may account for the accidents which frequently befall the China blue process in unskilful hands. The blues sometimes scale off, from the paste being dried too hard before the goods are dipped. When the temperature of the vat-liquors is too low, the blues get a gray tint, and are always dull.

Fourth style.—Steam colours; in which a mixture of mordants and dye-extracts is applied to the cloth, and the chemical combination is effected by the agency of steam. This modern style combines with the beauty of colour such a degree of solidity as can be obtained only

by the madder copper. An example will illustrate the mode of procedure. The goods are to be padded in the following mordant at a specific gravity of 1.047. In 30 gallons of boiling water dissolve 30 lbs. of alum, 5 lbs. of dry carbonate of soda, and 15 lbs. of acetate of lead. After mixture and subsidence, draw off the supernatant acetate of alumina. After being padded, the goods are to be dried over the hot flue, and, after being hung up three days, they are to be washed in chalky water at 133° Fahr., then rinsed in clear water and dried. The goods should be smoothed by the calender before being printed. A mordant for steam-colour may be thus prepared. Dissolve in 7 gallons of boiling water 10 lbs. of alum, 5 lbs. of acetate of lead, and 20 oz. of sal ammoniac. Let the mixture settle; decant the supernatant liquor, of specific gravity 1.075; and thicken with gum. Black figures are given by printing on the following paste. In two quarts of strong decoction of logwood, thickened with 8 oz. of starch, dissolve, while tepid, 2 oz. of sulphate of iron. Pour into a pipkin containing 1 oz. of olive oil; stir, and when it is cold, add 4 oz. of nitrate of iron containing a little acetate.

Other colours are produced as follows. For a full-bodied red, thicken 2 quarts of a strong decoction of peach-wood by boiling 8 oz. of starch in it; when cold, add 12 oz. of solution of nitromuriate of tin. For a steam-blue with Prussiate of iron; dissolve in one quart of water 3 oz. of oxalic acid, or 3½ oz. of tartaric; and in another quart dissolve 6 oz. of prussiate of potash; mix these two solutions, let them settle during twenty-four hours, decant the clear supernatant liquor, and thicken it with 1¼ lb. of gum. A steam-green paste is prepared by adding to the preceding blue a strong decoction of Persian berries, mixed with the above aluminous mordant containing sal ammoniac, and thickened; the proportions of the yellow and blue pastes determine the shade of green. The supernatant liquid of the blue formula contains ferrocyanic acid, convertible, by the steam-heat and the agency of the vegetable acid, into Prussian blue, which fixes on the cloths. For producing lemon-yellow; take 2 quarts of a decoction of Persian berries, made from 2 lbs. of berries, 2 quarts of the above mordant with sal ammoniac, thickened with 3 lbs. of gum.

The goods, after having one or more of these or other such colours printed on them with the cylinder machine, should be suspended for two days in a chamber of a temperature not exceeding 88° Fahr. The colours are afterwards raised and fixed by the application of dry steam; for any aqueous condensation will spoil the prints. There are five kinds of apparatus for applying steam in steam-colour printing:—the column or cylinder; the lantern; the cask; the steam-chest; and the chamber. We shall content ourselves with describing the column, as it is most generally used in this country. It is a hollow cylinder of copper from two to six inches in diameter, and about forty-five inches in length, perforated along its whole surface with small holes about one-sixteenth of an inch in diameter, and one quarter of an inch apart. To the lower end of the cylinder a circular plate is soldered of about nine inches diameter, which serves to prevent the cloth coiled round the cylinder from falling down from it. The bottom of the hollow cylinder is terminated by a tube one inch wide, which fits tight into the socket of an iron chest beneath it, into whose side the steam-pipe of supply enters. The water condensed from the steam is also received into that chest, and may be run off by means of a stop-cock near its bottom. In some cylinders the steam is admitted at the top, and the condensed water is allowed to run off by a small siphon tube at the bottom. The goods printed with the above steam-colours and properly dried are lapped tight round this hollow cylinder and covered exteriorly with an envelope of strong cotton cloth, blanket-stuff, or flannel. The steam is then let on, and continued for twenty or thirty minutes, according to the nature of the dyes. The steam being stopped, the printed goods are rapidly unrolled from the column while still hot, lest any condensation of vapour should take place to stain them.

Fifth Style.—Spirit colours. These are brilliant, but fugitive; they consist generally of decoctions of dye-woods, mixed with nitromuriate or muriate of tin. The following red will serve as an example. Thicken two quarts of decoction of peach wood with four ounces of starch; dissolve in the paste while hot four ounces of alum; add to the mixture when cold four ounces of oxymuriate (perchloride) of tin, and two drachms of sulphate of copper. This and similar colours are applied by the two, three, or four-coloured printing-machine, and passed through a drying room slightly heated. The goods are next tenderly rinsed in running water; afterwards washed, and dried quickly, but with a moderate heat.

The above are the general principles and processes of calico-printing. We shall now treat briefly of two or three collateral matters.

It would scarcely be possible, if necessary, to notice all the patented improvements in calico-printing, introduced within the last few years. Nor would it, indeed, be desirable; for however they may differ in detail, the leading principles remain nearly unaltered. A clever chemist—and there are now clever chemists in all the print-works of any note—will devise a new mordant for a particular colour, or a new drug for a particular dye; he may find new modes of conducting the many remarkable processes incidental to the printing; the skilled machinists of Lancashire and Glasgow may invent new forms of machinery; and artistic designers may throw new beauty into the designs and patterns selected; but there are certain general points of

resemblance in all these arrangements. There is one novelty, however, which we must notice, as it drew forth an honorary medal from the Society of Arts. The Society offered a premium in 1853 for "Improvements in machinery for printing calico and other fabrics, by which ten or more different colours may be worked simultaneously, and with accurate register." The motive for this offer was, to produce if possible as delicate printing by the machine as by the block method. "Of late years, cylinder machines for printing cheap cotton and other fabrics have attracted much attention, to the neglect of the ordinary block machines, which are known to produce a superior article in point of softness and artistic effect." Mr. Dalton, of the Hollingworth calico print works, near Mottram, thereupon sent a paper and a model to the Society, which gained for him a silver medal, as one who had responded to the invitation sent out by the Society. He had long known the inefficiency of the iron cylinders, with their folds of lapping and their endless webs, as ordinarily used. "It is of primary importance to the attainment of a perfect impression from the engraved rollers on the cloth, that the surface of such medium should be perfectly smooth and even, and should also possess sufficient softness and elasticity to enable the cloth to take up the colour from the depressed lines of the engraving, without being in itself permanently indented or marked by the pressure. It is a matter of extreme difficulty to obtain these desiderata by the usual mechanical arrangement. Numerous inequalities in the texture, and slight variations in thickness, exist in the newest webs; and after being a short time subjected to the abrasive action of the machinery, accumulations of woollen particles, termed in the trade 'flocking,' This unevenness of surface necessarily occasions a corresponding variation in the depth of shade produced by the impression, and an omission altogether of the finer lines of the pattern." This led Mr. Dalton to the use of an impression-cylinder covered with an inch and a-half of gutta percha, and so arranged as to work without lapping or webbing. This cylinder he calls a *bowl*, but it will be more familiar to ordinary readers to call it a *roller*. He employs two wholly distinct forms of apparatus for applying the rollers. *First method.*—Having prepared a gutta-percha roller, solid, elastic, smooth, and even, suitable for producing a uniformity and regularity of impression, a saving of power and an economy both of material and of labour, he surrounds it with ten engraved cylinders (supposing there to be ten colours in the design). The cylinders are pressed against the gutta-percha rollers by screws and springs, each having its colour-box and its spreaders. The different parts of the machine being properly adjusted, the calico is brought into contact with the roller, clings to its surface, and travels on as it revolves, receiving as it goes the pressure of the first engraved cylinder. The elastic surface of the roller gives way to the pressure sufficiently to enable the depressed lines of the engraving to imprint the colours on the cloth without any consequent depression remaining on the roller. The cloth travels on around the roller, receiving an impression from each cylinder in turn, all falling precisely in register, or on the proper places. *Second method.*—This differs very materially from the former. The machinery is in three sections, each with three gutta-percha rollers. The two outer rollers of each section are pressed upon the engraved cylinder by weights and levers; the central one is pressed by springs and screws. The engraved copper cylinders are placed at equal distances horizontally, in such way that the pressure from each roller is received by the two cylinders revolving in contact with it. Thus the first and last cylinders receive the pressure of one roller only each; whereas all the others receive the pressure of two rollers. The calico, unwinding from its roll, travels to the first roller, where it receives the impression of colour from the first cylinder; passing on with the revolution of the roller, it receives an impression of another colour from the second cylinder; moving with this second cylinder, a second impression is given to it by the second roller—thus receiving what is technically called two "nips" by each cylinder, except the first and the last. The advantage sought for by this "nip" is to bring out the impression more fully and forcibly on the fabric; and in case the pressure of the first roller should chance to be ineffective, the omission will be rectified on its coming into contact with the second roller. Thus the calico traverses the whole machine, receiving ten colours one after another in its passage. In the ordinary method of cylinder calico-printing, the pressure is made by each engraved cylinder against the blanketed cylinder; but in Mr. Dalton's method, the gutta-percha presses against the engraved cylinder; by which any casual variation or inequality on the surface of the cloth will merely affect the pressure roller, without producing any injury.

The establishments in which calico-printing is conducted are among the most interesting of our scenes of industry. In those belonging to the leading manufacturers there is always a chemical department, comprising not only a store of all kinds of drugs and dyes required, but every requisite for making experiments on the almost numberless mordants, baths, pigments, oils, acids, alkalis, &c.; retorts, sand-baths, furnaces, stills, steam-heaters, mixing vessels, crushing and grinding apparatus, all are here to be seen. Then there is the artistic department, in which the important matters of design and pattern are treated; if it be an establishment (there are such) in which the owners do not scruple to appropriate the patterns of another firm, the artistic department is little other than a place where stolen goods may be sophisticated to escape detection; but in the honestly

conducted print-works, designers are well paid to produce novel and beautiful patterns. Then there is the engraving department, where the designs are transferred to wood blocks, metal plates, or metal cylinders, according to the kind of work to be done. Out of a hundred designs made on paper there may be eighty rejected as inappropriate; and out of the remaining twenty engraved, there may not be more than two or three which possess the double excellence of being practicable to work and attractive in their tasteful appearance. Under any circumstances, the expense of these drawings and engravings is enormous; but on the other hand, a thoroughly successful pattern sometimes proves a fortune to its owners. Among the other departments of such establishments is the "cloth room," where the calico or muslin is thoroughly examined before printing; the "block-printing rooms" and "cylinder-printing rooms," in which processes are carried on indicated by those names; mangling-rooms, starching-rooms, drying-rooms, examining-rooms, packing-rooms, &c.; besides all the engineering workshops and apparatus necessary for the daily repair of a large assemblage of machinery. Some of the cylinder-machines will print calico at the rate of a mile an hour each; and it is in this way that the productive powers of such establishments become so enormous.

We shall now briefly notice the legislative arrangements relating to the management of print-works.

When the first "Factories' Act" passed, limiting and contracting the power of employing children in factories, many members of both Houses of Parliament wished its provisions to apply to calico print-works, as well as to spinning and weaving mills; but this was not acceded to. The subject was, however, afterwards taken up with great earnestness; and in 1845 Lord Ashley (the present Earl of Shaftesbury) brought in a Bill for extending the Factories' Act to print-works, with certain modifications depending on the exigencies of the trade. Commissioners, appointed in 1840 to investigate this and collateral matters, said in their report, in reference to print-works:—"In Lancashire, Cheshire, and Derbyshire, instances occur in which children begin work in this employment at as early as between four and five, and several between five and six inclusive; many begin between six and seven, and the great majority between eight and nine. Out of 565 children taken indiscriminately from returns obtained for each section of this district, it appears that one child began work between four and five; 3 between five and six; 68 between six and seven; 133 between seven and eight; 156 between eight and nine; 127 between nine and ten; 49 between ten and eleven; 26 between eleven and twelve; and 2 between twelve and thirteen. In the east of Scotland children commence work at the same early ages." The Commissioners moreover found that these children worked in rooms at a temperature varying from 65° to 110° Fahr., the latter being sometimes the degree of heat in the stove-rooms, where the goods are placed to dry. Some of the children occasionally fainted under the influence of this tremendous heat; those engaged near the dash-wheels had their feet and dresses saturated with wet. The hours of labour, too, were very great for such young persons; nominally, they were twelve per day, but really they averaged fourteen or fifteen; and in busy times there was scarcely any other limit than that which human strength could bear. Health was affected; education was neglected; morals deteriorated. Basing his reasonings on the facts stated in this report and on subsequent inquiries, Lord Ashley drew up his Bill. Sir James Graham, on the part of the Government, without opposing the measure, pointed out the necessity of caution in dealing with such a subject, lest, in protecting the children, we should paralyse the trade itself. He urged, that the work of children is absolutely necessary; that print-works are not, in general, unhealthy places; and that, as there are periods of great demand alternating with very slack seasons in that trade, any fixed arrangement of hours might be disastrous. Nearly 25,000 children were supposed to be employed in the print-works of the United Kingdom; and it became, therefore, a grave question how far, and in what way, to interfere in this peculiar department of industry. Between the periods of the first and second reading of the Bill, Sir James Graham, as Home Secretary, caused all the inspectors of factories to examine the Bill with the light of their own personal experience, and to attend to such objections as the master-printers might urge against it. The result of these inquiries was, to induce the Government to assent to the Bill in a modified form. Lord Ashley had proposed that its provisions should apply to bleach-works, dye-works, and calendering-works, as well as to print-works; but Sir James Graham would only agree to the last-named application. He agreed to prohibit the employment of children under a certain specified age, and to prohibit night-work by children; but in neither direction would he go so far as the Bill proposed. Lord Ashley was very unwilling to modify his measure; but he accepted the Government offer as a means of securing the passing of a Bill, which would at any rate be a movement in the wished-for direction, and which would not preclude further measures of a similar kind in subsequent sessions. Receiving certain amendments in both houses, it passed into law, and became the Act, 8 & 9 Vict. c. 29.

Of this Statute we give a brief outline. The Act came into operation on the 1st of January, 1846. To define the terms used, "child" is declared to mean a person under thirteen years of age; "young person," between thirteen and sixteen; "a day," from six in the

morning till ten in the evening; "night," from ten in the evening till six in the morning. The inspectors of factories to be inspectors of print-works under this Act. Inspectors empowered to enter any print-work, and examine into all matters connected with the employment of children and young persons therein. No children or young persons to be employed without a certificate from a surgeon, countersigned by a magistrate. No child to be employed under eight years of age, and no child or young person at night. A certain amount of schooling prescribed for every child and young person, and the schoolmaster to be controlled in certain matters by the inspectors. A good clock, a register of attendance, a copy of the Act, and a set of printed rules, to be kept in each print-work. Finally, the Statute laid down the requisite means for enforcing obedience to its provisions.

Calico print-works have ever since remained under the influence of this Statute, subject to only minor alterations. It has been shown, under BLEACHING, that bleach and dye-works have not yet been brought under the regulations which apply to cotton-mills and print-works, although many attempts have been made in that direction.

Concerning the extent of the trade in printed calicoes and muslins, very little of a precise kind can now be stated; for the home consumption is not interfered with, or registered by, any legislative enactment. Something on this subject will be found under COTTON TRADE AND CONSUMPTION. In the present place we will merely state the quantity of printed and dyed calicoes exported within the last few years. This does not mark the full extent of the export trade; for there is another (but very small) entry, under the confused heading of "Cambrics and muslins, plain and printed or dyed," in the Board of Trade tables; this entry is so small in amount that we may disregard it.

1849	.	.	.	.	530 millions of yards.
1850	.	.	.	.	576 " "
1851	.	.	.	.	569 " "

The quantities are here given in round numbers, sufficiently near for the purpose. The marked extension of the trade in the last three years will not fail to be observed.

CALIPH, CALIPHAT. Caliph, properly *Khaleefeh*, is an Arabic word, which primarily denotes a successor or vicar, and was at first given to the sovereigns of the Muslim Arabs, as signifying successor to the Prophet; but is generally used in a more limited sense, as the title of certain dynasties of Mohammedan sovereigns. It was first adopted by Abu Bekr, the immediate successor of Mohammed, and, together with *Emir-al-Mâmenîn*, "the commander of the faithful," continued for several centuries to be the title of the principal line of Mohammedan sovereigns. The word Caliph (Arabic, *Khaleefat*) is used both as a general designation of the line of sovereigns called caliphs, and, in a geographical sense, for the extent of countries subject to their dominion. The principal of these caliphats were Spain, Africa, Egypt, and Bagdad.

CALLUTANNIC ACID. [TANNIC ACIDS.]

CALMS (at sea) occur at certain seasons in every part of the ocean, except perhaps the parts near the poles; but they seem to increase in frequency and duration as we approach the equator, and in the immediate vicinity of the equator there is an immense extent of sea, in which they are so prevalent that it has been called the *region of calms*. The calms, however, do not always occupy the same portion of the ocean, but they vary according to the position of the sun. When the sun is in the northern hemisphere, they are sometimes found to extend as far as 15° N. lat., and then the S.-E. trade-wind passes four or five, or even six degrees to the N. of the equator. When the sun is in the southern hemisphere, the calms also occur to the N. of the equator, but they come very near to it and sometimes reach it, whilst their northern border extends to 60° or 70° N. lat. Thus it appears that this region of calms does not extend on both sides of the equator, but is entirely in the N. hemisphere, which arises from the circumstance that, on account of the unequal distribution of land and water in the two hemispheres, the terrestrial equator is not the line of greatest heat. In some seasons the calms extend over eight or even nine degrees of latitude; at others over a smaller space, and sometimes only over two and a half or three degrees. The average breadth of the region of calms is about six degrees. These remarks refer to the Atlantic Ocean. In the Pacific an equatorial belt of about five degrees in breadth, of such habitual calms as to have given that name to the ocean itself, lies between the north-eastern and south-eastern trade-winds. This is a belt of constant precipitation of the aqueous constituent of the atmosphere. Captain Wilkes, of the American Exploring Expedition, when he crossed it in 1838, found it to extend from 4° to 12° N. He was ten days in crossing it; and during those ten days rain fell to the depth of 6.15 inches, or at

the rate of eighteen feet and upwards during the year. For about sixty degrees of W. latitude, from 120° to 180° , this belt, according to Lieut. Maury, is in the southern hemisphere, its northern edge coinciding very nearly with the equator; this southerly depression of the region is probably occasioned by the great extent of open sea in the Pacific. In the colloquial language of seamen the equatorial calms are designated the *Doldrums*.

In the Atlantic region of calms known as the *Variables*, which separates the N.-E. and S.-E. trade-winds,—being produced by their neutralisation of each other, a neutralisation so complete that far at sea a candle burns without flickering,—the calms do not continue without interruption. Sometimes light breezes blow, especially from the S. and S.S.W. Besides this the calms are commonly interrupted every day by a wind which lasts a quarter of an hour or twenty minutes. After noon a black and well-defined cloud is formed near the E. horizon, which seems to announce a violent thunderstorm. The cloud increases, a wind suddenly rises, and blows with great violence for a few minutes. It is accompanied by a few drops of rain, but in a few minutes the rain ceases, the air reassumes its clearness, and the calm returns. These daily squalls, though of short duration, enable the navigator to pass the region of calms, which even with this aid always proves very disagreeable. Violent thunderstorms, however, frequently actually occur. These calms, united to the immense quantity of fucus or gulf-weed which is found W. of the Cape Verde Islands, may have given rise to the opinion of the ancients that the sea near the equator grows shallow, and becomes a swamp unsuited for navigation.

Parallel, in each hemisphere, to the equatorial belt of calms, are the "horse latitudes" of seamen, which are zones of calms bordering, respectively, the north-east trade-winds on the north, and the south-east on the south, which also follow the declination of the sun; along the polar border of each is another region of precipitation, though the rains are generally less constant than in the equatorial calms.

(Horsburgh, *India Directory*; Rennell's *Invest.*; Humboldt; Mrs. Somerville's *Physical Geography*; Maury's *Physical Geography of the Sea*).

To witness and examine the actual phenomena of contact of the winds blowing from opposite or different quarters, where the neutralisation, or production of calm, begins, must always be difficult; partly from our ignorance of the precise locality, and often from its inaccessibility when known. In the case of the trade-winds alluded to in this article, it must begin in variable planes, perpendicular or inclined to the horizon. But of the phenomena attending the production of a calm region at a great elevation, by the neutralisation by each other of the north-east trade-wind, and the south-west wind above it, in planes approximately horizontal, we have some particulars in Professor C. Piazzzi Smyth's 'Report of the Tenerife Astronomical Experiment of 1856,' pp. 480, 481. At the observing station of Mount Guajara, on the Peak, the altitude of which was 8903 feet, in July and August, he observed that the tops of the lower hills of the island, at about the level of the trade-wind cloud, or 4000 feet, were swept by the wind with terrific force; "but above that height," he states, "the wind, still preserving the same N.-E. direction, continually decreases in strength, until it reaches a neutral stratum below the S.-W. wind, which appears there to be always the direction of the upper current in the atmosphere, in the summer at least, for which season alone my descriptions are intended to apply. The height of this neutral region would seem to vary much; sometimes it was below, but much more generally above 9000 feet. Hence we had more N.-E. wind than S.-W. at Guajara; but being in the neighbourhood of the neutral stratum, neither wind was felt in great force, except on one occasion, when for several hours in the evening the N.-E. wind blew with a velocity of from twenty to thirty miles per hour." At his second station of "Alta Vista," at the height of 10,700 feet, there was on the whole less wind than at Guajara, and it was more evenly balanced between the two directions. In his work entitled 'Tenerife, an Astronomer's Experiment,' p. 382, Prof. Smyth adds, that on September 19th, when he left the mountain, from the upper station "the N.-E. trade, the characteristic of a Canarian summer, was gone, and the S.-W. wind, though blowing on the mountain-top, had not yet descended to take possession for the winter of those lower zones; where a meteorologic interregnum was in consequence evidently prevailing. The air, however, was exquisitely transparent." [WINDS, TRADE.]

CALMUCKS, or KALMUCKS, is the name given by the Russians to one of the principal branches of that division of the Mongols which bears the general name of Olöth, or Oirat. This nation is more widely dispersed over the globe than any other uncivilised people, the Arabs not excepted. Calmuck tribes occur over all the countries of Upper Asia between 38° and 52° N. lat., and from the most northern bend of the Hoang-ho to the banks of the Volga. We are acquainted with four principal branches. The Olöth inhabited chiefly the centre of these countries, to the south and north of the Thian-Shan range, in the present Chinese government of Ili, whence they extended their conquests over the neighbouring tribes during the 17th century, and founded an empire of great extent and power, which was destroyed by the Chinese emperor Kang-hi in 1698. Upon this event, the name of Olöth merged in that of Zoongars, another numerous nation of the same origin, which inhabited the adjacent countries. The Zoongars also

were for a short time formidable to the neighbouring tribes, especially the Khalkas, or proper Mongols: their empire was destroyed by the Chinese in 1757. By these continual and unsuccessful wars both nations have nearly been annihilated, and their names have almost disappeared. The Turbut, or Derbet, forming the third principal branch, had long before these events submitted to the Chinese emperors; and, united with the remnant of the Zoongars, they still inhabit the countries about the lake of Koo-koo-nor, and along the Hoang-ho river, where it forms its great northern bend. They are considered and treated by the Chinese rather as allies than as subjects. A few also joined themselves to the Toorgoots.

The fourth branch of the Olöth, which received the name of Calmucks from the Russians, is properly called Toorgoot, and inhabited the countries west of those of the proper Olöth. But during the continual wars which they had to wage with these more powerful neighbours, they began to extend their excursions towards the west, and at last settled, with the permission of the Russians, in the steppes which extend between the Volga and the Ural, in 1672. There they remained nearly a century; but in 1771, after having repeatedly been invited by the Chinese to return to their native country, the greatest part of them suddenly left the Russian territories, and returned, by a march of eight months, to the banks of the river Ili, where the countries whose inhabitants had been destroyed in the wars between the Chinese and Zoongars were assigned to them by the Chinese. Their number was estimated at 50,000 families, or 300,000 souls. The smaller portion of the nation, estimated at 12,000 families, remained in Russia, and their descendants yet inhabit the country betwixt the Don, the Volga, and the Kuma.

In the form of their body the Calmucks resemble the Mongols, and the languages of the two nations differ perhaps not more than the Italian and the Spanish; but the proper Mongols have a rich literature, while that of the Calmucks seems to be limited to a few compositions or translations respecting the tenets of Buddhism, a religion which has been embraced by all the nations of Mongol origin.

The Calmucks have no fixed abodes, but movable huts, called kybitkas, which they carry from one place to another, in order to be always near the best pasture for their herds. They live entirely upon animal food, and do not cultivate the ground. They have large numbers of camels, horses, and sheep, but not many cattle. Their horses are of a middling size, very strong and swift. Their sheep are of the same kind as those of the Khirgis, with large tails and good wool, of which the women make different stuffs for dresses, blankets, coverings for the kybitkas, &c.

They are not the immediate subjects of the princes in whose countries they live, but have their own hereditary chiefs, and an hereditary nobility, to whom they are much attached, and to whom they pay strict obedience. Their military or marauding excursions, to which they are much inclined, owing to their wandering habits of life, make them very troublesome to their neighbours.

CALOMEL. [MERCURY, CHLORIDE OF.]

CALORIC. [HEAT.]

CALORIC ENGINE. In the article AIR ENGINE an account was given of certain contrivances intended to have the power of steam-engines without the use of steam. Most of the machines there noticed require the action of air, wholly or in part heated; but a reference was made to the present article for a brief account of certain air-engines which have acquired some notoriety under the name of *caloric engines*.

The theory of caloric engines is by new means a new one. Besides the inventions of Stirling, Von Rathen, and Randolph, described in the article just quoted, there have been many others depending on an analogous principle. Sir George Cayley made many attempts in this direction. In 1827 Messrs. Parkinson and Crossley followed in the same track. Mr. Parsey has made many experiments, and taken out more than one patent, for hot-air engines. One of his patents, under date 1854, comprised the employment of an improved pump, for compressing or exhausting air; an aërometer or movable reservoir for storing air, and giving it out again under pressure; and a mode of heating the working cylinder of an engine. Mr. Shaw, an American inventor, has brought forward some contrivances intended (or hoped) to obtain more power from air than from steam. His engine comprises an oscillating horizontal cylinder, an air-compressing chamber, heating tubes, and various other adjuncts. The heat and smoke from a furnace are made to give up a portion of their caloric to air contained within certain tubes. An air-pump forces air from the atmosphere into a compressor, where it is maintained at 60 lb. on the square inch, and whence it passes into the tubes. There are many other parts of the apparatus, all contributing to the main purpose of moving a piston in a cylinder, thereby giving rotatory motion to a shaft. But there remains the objection so fatal to all such engines—that air requires the same amount of power to compress it as is obtained afterwards from the same air in the compressed state. Among all these inventors, however, the one who has bestowed the largest amount of attention on caloric engines is Captain Ericsson, to whose contrivances we shall at once proceed.

Ericsson's inventions, some patented and others not, have been brought before public attention during about a quarter of a century, his

first patent being dated 1833. The boldness of his theory, in reference to the powers ascribed to his caloric engine, attracted much attention a few years ago; for it went to the length of asserting that hot air, when brought into contact with an extensive surface of iron wire gauze, is deprived of its heat; that this heat may be the next moment imparted to an incoming current of cold air; that these duplicate processes may take place over and over again; that fuel will be required only for the first action, with a little surplus for radiation; and that thus an engine might be worked continuously with scarcely any continuous expenditure for coal. Captain Ericsson seems to have modified his views at different times; but in 1854 he undoubtedly believed that the same portion of heat can be made to produce mechanical power over and over again. In a lecture at Boston (U.S.) in that year, by an advocate of Ericsson's views, the lecturer said: "The object of Ericsson's caloric engine is the production of mechanical power by the agency of heat, at an expenditure of fuel so exceedingly small that man will have an almost unlimited mechanical force at his command, in regions where fuel may now be said hardly to exist. The announcement of such an idea may startle all those acquainted with the nature of heat, and the well-known limits to the amount of mechanical power which any given quantity of caloric is capable of producing. . . . Ericsson's theory of heat is altogether in opposition to the received notion that the mechanical force produced will bear a direct known proportion to the quantity of caloric generated. . . . The basis of the caloric engine is that of returning the heat, at each stroke of the piston, and using it over and over again. . . . This result Captain Ericsson has accomplished by means of an apparatus which he styles a *regenerator*; and so perfectly does it operate, that the heat employed in first setting the engine in motion continues to sustain it in full working force, with no other renewal or addition than may be requisite to supply the inconsiderable loss by radiation."

Civil engineers in England and America have not been slow to predict the inevitable failure of any mechanism based on this theory. Professor Ewbank, in the 'Journal of the Franklin Institute,' has treated the Ericsson theory of heat as essentially unsound, in relation to mechanical appliances. Leaving untouched the acknowledged ingenuity displayed in the mechanism of the caloric engine, and avoiding equally the question of the absolute mechanical equivalent of a given amount of heat, he confines himself to an inquiry into the reproductive powers claimed for the new apparatus. After adverting to the fallacies of perpetual motion, and the defeat of the hopes of all who in this way have sought to create power out of nothing, he adds: "There are those who discard as absurd all attempts to gain power by wheels, springs, and levers, and yet imagine they can get it by fluids, without giving anything like the usual price for it; and so specious have these plans appeared, that both experienced and inexperienced men have been led astray." Speaking of Ericsson's invention, the professor remarks: "The principle on which his invention rests is, the repeated use of the same caloric. In this engine, as in the steam-engine, heat is the animating principle; and in using over and over the same heat, he virtually uses over and over the same power. He claims to have succeeded in seizing upwards of 90 per cent. of heat expended in raising a loaded piston, and in returning and compelling it to do the same work over again. The regenerator, though an ingenious device, is not what its name implies. It is at best but an *economiser* of heat, in the same sense and after the same manner as contrivances by which the waste steam of engines impart heat to cold water."

It would not be practicable to describe Captain Ericsson's caloric engine (or rather engines; for he has invented many, differing considerably one from another) in detail, without an absorption of greater space than the subject would justify; but an outline of the experiments made public may be given in a few words.

In the summer of 1852, two of Ericsson's caloric engines were at work in a factory at New York; and as newspaper paragraphs frequently appeared, presenting most favourable accounts of the working of these engines, arrangements were planned for building a ship of 1000 tons burden, to be propelled by hot air instead of by steam. It was anticipated that the Atlantic might be crossed by such a ship in fifteen days, and at a vastly cheaper rate than by the superb but costly Cunard steamers, thereby more than compensating for the quicker passage of the latter. The ship was 250 feet long, and had paddle-wheels 32 feet in diameter. On its first trial trip, in the early part of 1853, the ship made twelve knots an hour with the wind, and answered the helm well; she used only six tons of fuel per day, and was pronounced to be a beautiful ship, even irrespective of her caloric. Such, at least, was the account given by the inventor and proprietors; but it was remarked at the time, that disinterested persons were not afforded the means of verifying this report. On the second trial, the maximum speed attained was nine knots—obtained, as asserted, at a cost only one-sixth of that of steam. After this, unfavourable circumstances one by one came to light; and the ship, named the 'Ericsson,' in honour of the inventor, failed to establish the validity of the principle involved. Influenced by the results of further experiments made in 1854, the indefatigable inventor took out another patent in 1855, for certain novelties in the apparatus. In this new caloric engine, the heated air, after performing its duty by raising the piston in the working cylinder, is made to circulate through a vessel containing a series of tubes; and the current of heated air, in passing through this vessel or

regenerator, is met by a current of cold air, circulating in an opposite direction through the series of tubes in its way to the working cylinder. Thus there is cold air within the tubes and hot air without; an interchange takes place, or rather an equalisation, by a transference of caloric from one to the other. The current of cold air, on its way to the working cylinder, after having thus been partially heated by the transference of caloric, is made to pass through a series of tubes or vessels exposed to the fire of a furnace. The action of the engine itself is what is called "differential," the motive energy depending on the difference of areas in the working and supply cylinders. The heater and regenerator are supplied with fresh compressed atmospheric air at each stroke of the engine. In the year now under notice (1855), the old caloric engine was taken out of the 'Ericsson,' and steam-engines substituted. Captain Ericsson would not admit, however, that this was an evidence of failure in his plans; he asserted the soundness of the principle, and the economy in fuel. The first engine made, was, he said, too cumbrous for the available amount of power in the ship, and the losses by leakage and friction were greater than had been anticipated. A second was made; but the joints of the pipes of the heaters were not good, and could not bear a greater pressure than such as would produce a speed of seven knots an hour. Surcharged or overheated steam was used, because the hot air escaped; and then occurred a dislocation of the whole machinery by an explosion. This accident led to the substitution of steam-boilers; but even then Ericsson would not admit that the principle of his caloric engine was proved to be unsound; seeing that the accident had arisen from mechanical defects, and that the change consisted only in the use of steam-boilers instead of air-heaters.

So far as concerns the principle put forth by Captain Ericsson, the results hitherto obtained justify the objections taken to it by engineers. Nevertheless, the peculiar action of the regenerator has been much admired; and if this apparatus were designated an *economiser*, instead of a regenerator, its prospective usefulness might be recognised. It is still believed by many engineers, that there are certain conditions under which hot air would be preferable to steam as a motive power. Mr. Hawkins, at the Liverpool meeting of the British Association in 1854, offered reasons for thinking that the maximum theoretical efficiency of air-engines, consistently with safety, is higher than that of steam-engines. So far as concerns Ericsson's caloric engines, some of small power, applicable to factory operations, are admitted to indicate an economy of fuel.

CALORIMETER. [HEAT.]

CALOTYPE. [PHOTOGRAPHY.]

CALOYER (*καλογερας*), the name given to the Greek monks, from kalos and geras, meaning comely, venerable old age. They are mostly of the order of St. Basilus, and inhabit convents, the principal of which are on Mount Athos. They are bound to celibacy, which is not the case with the secular clergy or papas of the Greek church. The Caloyers abstain from meat, and observe six Lents in the year, besides other fasts, at which times they abstain also from butter, eggs, and fish, and live only upon bread, vegetables, salt, and water. There are also convents of female Caloyers.

CALTROP, commonly called Chausse-trape or Crow's-foot, a piece of iron formed with four points, each about three inches long, which are so disposed, that, when the piece is thrown on the ground, one of them stands always upwards. In warfare crow's-feet are sometimes scattered about in order to impede the march of cavalry, especially in fords, &c.

CALUMET, the name given by the North American Indians to a pipe for smoking tobacco. In Harris's 'Voyages,' vol. ii., p. 908, the following description of this pipe is given: "The calumet or pipe of peace is a large tobacco pipe, with a bowl of polished marble, and a stem two feet and a half long, made of strong reed, adorned with feathers and locks of women's hair. When it is used in treaties and embassies, the Indians fill the calumet with the best tobacco, and presenting it to those with whom they have concluded any great affair, smoke out of it after them." To refuse the calumet is a sign of hostility. It is offered to strangers as a mark of hospitality. To smoke the calumet of peace literally signifies, in the language of the North American Indians, "to be on terms of friendship and alliance."

CALVINISM. [CALVIN, JOHN, in BIOG. DIV.]

CALX. [CALCINATION.]

CAMALDOLENSES, CAMALDOLITES, a religious order founded by St. Romualdo, at the beginning of the 11th century. The order was a reform of that of the Benedictines, whose constitutions St. Romualdo retained, with some modifications of additional strictness, one of which is the silence enjoined to members of the community. The dress of the Camaldolites is white, and they wear their beards long. The first establishment of the order was in the high Apennines, above the Casentino, or valley of the Upper Arno. The order of Camaldolites, like other branches of the Benedictine order, has produced many learned men.

CAMBOGE. Though this gum-resin was made known in Europe by Clusius in 1605, the tree which yields it is not accurately ascertained. All writers agree in referring it to the tribe of the Guttiferae, and several authorities point to Stalagmites Cambogioides (Murray), which according to Wight and Arnott is a species of *Garcinia* (probably synonymous with *Garcinia cochinchensis* (Chois.), the *Oxycarpus*

cochinchensis of Louriero), as the source of the Siam camboge; while that of Ceylon is stated to be obtained from the *Xanthochymus ovalifolius*. (Roxb.) Others assign the Ceylon camboge to the *Mangostana Morella*. (Derous. in Lamarck, 'Encyclo.' vol. iii. p. 701.) This last point it is of less importance to settle, if the statement of Dr. Christison be correct, that Ceylon camboge is not now an article of European commerce, all that is found in the markets of this country coming from China.

From the bruised leaves and young branches of the first-mentioned tree flows a yellow juice, which is received in cocoa-nut shells or earthen vessels; it is then allowed to thicken, and afterwards formed into rolls. This is the finest sort, called the pipe camboge of Siam. A portion is formed into round cakes, which are either entire or have a hole in the centre. This is the cake camboge of Siam.

The juice from the *Xanthochymus ovalifolius* flows spontaneously, but sparingly; it is increased by incisions in the stem, and by kindling fires in the vicinity of the tree. The colour of both kinds differs according to the season of the year, the age, and part of the tree from which the juice is obtained. The Siam camboge occurs in pieces of variable size, externally of a dirty yellowish brown colour, covered with a fine yellow powder. When broken they exhibit a conchoidal or vitreous fracture, with a brown or saffron-yellow colour.

At the ordinary temperature of the air camboge has little smell, but when heated it gives out a very peculiar one. Taken into the mouth it has scarcely any perceptible taste, but upon being chewed for some time it causes a sharp, somewhat acrid feeling, ending in a sweet sensation, accompanied with dryness in the mouth. It excites afterwards a flow of saliva, which is coloured yellow. Its specific gravity is 1.207. A specimen of pipe camboge of Siam, analysed by Dr. Christison, yielded as follows:—

Pipe Camboge of Siam.		Cake Camboge of Siam.	
Resin	74.2	Resin	64.8
Arabin	21.8	Arabin	20.2
Moisture	4.8	Fecula	5.6
Woody fibre, a trace.		Lignin	5.3
		Moisture	4.1

Of Ceylon camboge one specimen yielded—

Resin	75.5
Arabin	18.3
Cerasin	0.7
Moisture	4.8

The cake camboge is not entirely a natural production, but a manufactured article.

Camboge is almost entirely soluble in alcohol, and is not precipitated from solution by the addition of water. With water it forms an emulsion in which the resin is kept suspended by the gum. It is soluble in the alkalies. The resin may be considered its active principle. It is remarkable that a substance possessed of such slight sensible qualities, having no smell, and scarcely any taste, should be so powerful in its action on the human frame. It is a drastic purgative; and in combination with alkalies, forms a most powerful hydragogue cathartic, occasioning numerous copious watery motions. In an overdose it causes excessive purging, sometimes vomiting; and if taken in large quantity, it produces inflammation of the intestines, mortification, and death.

The diseases in which it is most useful are ascites, or dropsical accumulations in the cavity of the abdomen, especially if accompanied with obstructions in the liver, or other abdominal viscera. It has also been employed against the tape-worm, and obstinate or habitual constipation. The doses must be carefully regulated, and only taken by the order of an intelligent and responsible medical attendant. Its use as a quack medicine has led in many cases to fatal results.

Yellow juices, which when inspissated form a substance resembling camboge, are obtained from several trees, both of the tribe of *Guttiferae* and *Hypericaceae*. *Garcinia pictoria* is stated by Mr. Royle ('Flora of the Himalaya,' p. 132) to yield a camboge, which in its crude and unprepared state is superior to every other kind; but it is not so permanent. The *Garcinia celebica* (Linn.) likewise furnishes some. Several species of *Vismia* (*Hypericaceae*) yield an American camboge of good quality;—*V. sessilifolia* (Pers.), *V. guianensis* (Pers.), *V. cayennensis* (Pers.), *V. micrantha* (Mart.), *Vismia baccifera* (Mart.). The *Hypericum pomiferum* (Roxb.) also yields a sort of camboge; and the *Argemone mexicana*.

Camboge is more extensively used as a pigment than as a medicine.

An artificial camboge is manufactured with turmeric and other materials. This should always be rejected.

CAMBRIC is one of the numerous varieties of flax or linen manufactures. It is supposed to have derived its name from having been first made at Cambray. It bears much the same relation to linen that muslin does to calico, being a very fine and thin fabric. Scotch cambric, now manufactured in large quantities, is a kind of imitation cambric, made from fine hard-twisted cotton. The French material *batiste* is a sort of Scotch cambric, to which dyes and printed colours are applied.

French cambrics are imported and Scotch cambric exported to some extent, but do not figure largely in the Board of Trade returns.

ARTS AND SCI. DIV. VOL. II.

CAMELLIA JAPONICA, or *Japan Rose*. The botanical description of this plant has been given in the NAT. HIST. DIV. [CAMELLIA.]

All the varieties of *Camellia Japonica* succeed best when treated as conservatory plants; that is, planted in the open border under glass, protected from frost, and freely exposed to light and air. They then grow into large evergreen bushes, covered with a dense foliage, upon which their gaudy flowers are beautifully relieved, and are far handsomer objects than when their roots are confined within the narrow compass of a garden-pot. Many of the varieties are nearly hardy, that is, they can bear the ordinary winters of England almost without protection; but then they are so very inferior to conservatory specimens, as to be little worth the having as out of door shrubs, unless upon our south-west coast, in some of the warm bays of Devonshire and Cornwall. They are multiplied by cuttings, grafts, and buds, and also by seeds; there are hundreds of varieties; the best are the double-white, the double-stripe (with the *Donkelarii*, which has a red and white stripe in a different style), the *C. myrtifolia*, *Chandlerii*, and *punctata*. They thrive best in half loam from rotted turfs, and half turfy peat, broken up very fine. After they have bloomed, or even while flowering, buds will be formed for the succeeding season. These, when forming at the top, or on long straggling branches, should be carefully pinched off, in order to induce the plant to become thick and bushy, as well as to prevent its wasting its strength; while all the buds that are well-placed should remain. After the plant has done flowering, it should be pruned of all useless or unsymmetrical branches. If they require to be shifted from one pot to a larger, this is the time for doing so. The plants may then remain in the greenhouse, where they should be secured plenty of air, but shaded from the sun during the hottest parts of the day, until they have made their growth. They should now be placed out of doors, sheltered from the mid-day sun, and guarded from high winds, until it is time to return them to the conservatory, which is about the month of September, so as to avoid the effects of the early frosts.

The *Camellia reticulata*, one of the finest species of the genus, remarkable for its net-marked leaves, and its semi-double rose-coloured flowers, can only be brought to perfection by being treated as a conservatory plant, and planted in a pit or greenhouse, in the open mould. If confined in a pot, its leaves are apt to become white and unhealthy. If placed in a bright hothouse, its leaves and flowers are rendered much deeper-coloured, but altogether smaller, and the shoots more stunted. This sort will not easily propagate, either by buds, or cuttings, or grafts, like the common camellia, but requires to have its young wood inarched upon healthy young camellia stocks, when it takes freely; but the parent plant, if many of its shoots are thus treated, suffers so much from the mutilation attendant upon the process, that it is two or three years before it is sufficiently recovered to submit again to the operation.

CAMELOPARDALUS, the camelopard or giraffe, a constellation formed by Hevelius. A line drawn from Capella to the pole-star passes right through the body of the constellation: the hind part precedes in right ascension, of which the whole ranges from four to eight hours. The letters are of course not in Bayer. The following are the principal stars:—

CAMEO, a gem or stone engraved in *rilievo*; that is, in which the object represented is raised above the plane of the ground, in contradistinction to *INTAGLIO*, in which the subject is incised, or indented: strictly speaking the term cameo refers to such stones only as have strata or grounds of different colours. There has been much unsatisfactory discussion respecting the origin and exact meaning of the word cameo, and Ducange, Lessing, and others have quoted various ways of writing it.

The art of engraving stones is of high antiquity: but it was at the earlier periods, for the most part confined to *intaglio*, or indenting, a simpler and an easier process than relieving the work from a ground; and as such stones were used for signets or seals in very remote ages (Exod. xxviii. 11, 21, &c.), the *intaglio* mode of working seems to be the most natural as well as the best adapted to the purpose. For *intaglios*, transparent stones of a single colour, or at most clouded in colour (as the agates), were used; but for cameos, stones variegated in colour, or with colour in thin strata, as the onyxes and sardonyxes, were employed; artificial stones were also used.

It has been supposed that the Etruscans had the art of engraving hard stones before it was known to the Greeks; and from the forms resembling those of the *scarabæi* of the Egyptians, it has been thought that the Etruscans derived their knowledge from Egypt. Many engraved stones however that are called Etruscan, are doubtless early Greek, as may be inferred from their subjects, and from the occurrence in the inscriptions of characters of a Greek form.

The earliest Greek artist distinctly mentioned as an engraver of stones, is Theodorus of Samos; Herodotus (iii. 41) tells us that the famous ring of Polycrates "was the work of Theodorus, the son of

Telecles the Samian ;" though some writers speak of Mnesarchus, the father of Pythagoras, as an engraver of signets. There has been much discussion respecting the age and genealogy of Theodorus of Samos, and whether there were one or two sculptors of that name; the probability is that there were two, but the date of the Theodorus referred to by Herodotus is pretty well determined by the circumstance for which the historian mentions him, Polycrates having been murdered in 522 B.C. It is not, however, in the opinion of some, absolutely clear whether Theodorus engraved the stone or merely chased the metal of the ring of Polycrates. (Müller, 'Archäol. der Kunst,' § 97.) The first name of very great note that occurs in this branch of art is that of Pyrgoteles, who lived in the time of Alexander the Great, and who alone was permitted to engrave the portrait of Alexander. Tryphon deserves mention also in this place, being the author of a beautiful and well known cameo in the Marlborough collection, representing the marriage of Cupid and Psyche. He is supposed, on good authority, to have lived under the immediate successors of Alexander in Macedon.

The age of Augustus is remarkable for the excellence of the gem-engravers who were then living. Among these Dioscorides, or more correctly Dioscourides, held the highest rank. He seems, however, to have worked chiefly in intaglio. Some of his productions have reached our times, and prove that the estimation in which he was held was not undeserved. Dioscorides was under Augustus what Pyrgoteles had been under Alexander. From Augustus down to Marcus Aurelius there were engravers of gems, both in cameo and intaglio, of very distinguished merit. They were chiefly Grecian artists who settled in Rome. There were, however, some Roman gem-engravers who held a respectable rank, but the list is not considerable.

The Greek artists preferred representing the naked figure, and the finest works produced in Greece are seldom draped, while those executed in Rome, whether by native or by Greek artists, are for the most part clothed. Dioscorides continued to follow the taste of his own nation, and all his figures, with the exception of a Mercury, in the cabinet of France, are believed to be naked.

It is impossible to describe works of this sort, containing so much fine detail, with sufficient accuracy to convey a just idea of their merits. They must be seen and examined with care, to be properly appreciated. Celebrated cameos are preserved in most of the great museums of Europe. One of the most famous works is that known as the Gonzago cameo, which has the heads of Ptolemy II. and Arsinoë I. nearly six inches long; it is now in the possession of the Emperor of Russia. Another of the finest cameos known is the Apotheosis of Augustus, in the collection at Vienna. It represents Augustus, his wife Livia, as Rome, accompanied by her family, with Neptune and Cybele; another is of an Imperial Eagle; also a Ptolemy and Arsinoë, &c., &c. In the French collection the sardonyx of Tiberius is one of the best known: it exhibits the Apotheosis of Augustus and the princes of the house of Tiberius; a Jupiter Ægiocnus is a very fine specimen: to which may be added the Apotheosis of Germanicus; and one of Agrippina and Germanicus; with others, particularly some portraits of great interest. We possess in this country some camei of first-rate excellence, but they are chiefly in private collections. Almost without exception the most famous works of this kind are remarkable for the different strata or zones of colour which they exhibit, as well as for their exquisite design and execution.

The ancients were fond of decorating their drinking-cups with precious stones and *camei*. They called such vessels 'gemmae potariæ.' Many of them are preserved in the cabinets of the curious. They are usually of sardonyx.

The workers in cameo not only exercised their skill in the cutting or engraving, but also in so arranging their subject and the composition of its details as to make the different colours or zones of the stones answer for parts of the design; as, for example, in relieving fruit, flowers, or drapery, in colour, while the other parts, as the flesh of a portrait or figure, were left white; or cutting the subject entirely in white, and working no deeper into the stone than the first layer of colour; thus making, or rather leaving, a natural dark back-ground for the design. These irregularities or accidents, are sometimes taken advantage of so skilfully, that it is very difficult to decide whether the variety is the effect of art, or really the natural colour of the stone.

The ancients were so partial to this variously-coloured work, that they imitated the material, in glass or paste, and exquisite specimens of ancient pastes occur in the museums of this country and the continent.

At the decline of the Roman empire gem-engraving fell with the other arts, and it was not till a late period that the taste and munificence of the Florentine family of Medici caused its revival in Italy, and tempted artists to devote themselves to its practice. It was much encouraged in the 15th century. The wealthy required such works for ornamenting their dress, for inlaying and embossing vases, and similar display; and as objects in *rilievo* had a richer effect than others, cameo-collecting became a passion in Italy. Vasari and Marietti may be referred to as the historians of the Italian gem-engravers of that period: and the 15th and 16th centuries will be found to boast several very distinguished artists in this class. In the succeeding century there was a considerable falling off, but in the 18th the art again rose, and

the names of some who exercised it will bear comparison with those of almost any age. The greater part of these were Italians, but two of the most celebrated were natives of Germany, and are justly entitled to particular commemoration. The works of John Pickler and Lawrence Natter challenge competition with the finest antiques. Natter has left a valuable work on his art, entitled 'De la Méthode Antique de graver en Pierres fines,' &c. Raspe's 'Catalogue of Tassie's Gems' may also be consulted with advantage by those who desire to extend their knowledge on this subject; as well as the works of Millin, 'Introduction à l'Étude des Pierres gravées;' Raoul Rochette, 'Lettre à M. Schorn;' Visconti, 'Iconographie Grecque;' 'Impronte Gemmarie dell' Instituto;' Müller, 'Archäologie der Kunst,' §§ 313—315, &c.

The practice of working camei on shells, *conchylic*, is of comparatively modern introduction in Italy; but it is now carried to so great an extent, in Rome particularly, and exercised with such success, that we feel fully justified in including it in our notice of the art. The subject is worked in *rilievo* in the white portion or outer crust of the shell, while the inner surface, of a pink or reddish-brown tint, is left for the ground.

The art has never been sufficiently encouraged in this country to lead any great number of artists to pursue it exclusively; but England has, notwithstanding, produced a few eminent gem-engravers, and the names of Marchant, Brown, Tassie, and Pistrucci, particularly deserve honourable mention.

CAMERA LUCIDA, an instrument used for drawing, by which the images of external objects are thrown upon a plane or curved surface. Camera lucida signifies the light chamber, though the instrument contains no chamber; but it was so called because of its bearing a certain affinity to the camera obscura, a much older instrument, and after which it was named. [CAMERA OBSCURA.]

The camera lucida is an invention of the late Dr. Wollaston. It depends upon the phenomenon [REFRACTION] that when light is attempted to be thrown into a rarer medium from a denser at more than a certain angle, depending upon the two media, none will pass through, but all will be reflected. The following is the description of Dr. Wollaston's apparatus; modifications may be found in Coddington's 'Optical Instruments' and Sir David Brewster's treatise 'On Optics.' We omit detail of fittings and adjustments.

A B C D is the section of a glass prism, having an angle A D C of 135°. This is presented to the object to be represented in such a way that

the pencils of rays proceeding from it fall on the surface C D at an angle of 45° or nearly so, and therefore by the preceding principle, are reflected on A D, and again from A D to the eye, through an opening K L, which excludes all except the end of the prism at A, and a part of the sheet of paper or other flat surface G H. Hence the image of Q is thrown towards the visible part of the paper, and the eye viewing both the image and the sheet of paper (with different parts of the pupil, however, which creates a difficulty in using this instrument) the observer is enabled to trace the object upon the paper by means of one of the following adjustments:—

1. If Q be very distant, so that the rays of the pencils are nearly parallel, those rays will emerge nearly parallel, or the image will be at about the same distance beyond G H in appearance as the object Q is beyond B C. But the image must appear to be thrown *upon* the paper, or it cannot be distinctly traced. Either therefore the image of the paper must be removed to that of the object, or that of the object must be brought up to the paper. For long-sighted people, or those who see objects best at a distance, the first is most advantageous. It is done by placing a concave glass M, the principal focus of which shall be in or near the paper. The consequence is, that the pencils from the points of the paper are rendered nearly parallel, and by an adjustment for raising or lowering the lens the image of Q may be made to appear to coincide with that of the paper. But for short-sighted persons, who require near objects or divergent rays, the end may be answered by employing, instead of the convex lens at M, a concave lens at N, which makes the rays of the image diverge, and by adjustment of which they may be brought to appear as pencils diverging from the paper. Mr. Coddington has remarked that this lens must produce an unnecessary distortion of the image, and that a short-sighted person had better use the convex lens at M, in the manner of a long-sighted person; using spectacles, or placing a concave lens at K L, to bring the images nearer, or to render the rays more divergent.

2. When the object *q* is near the prism, the latter is raised or lowered on its pillar until the paper and the object are at equal or nearly equal distances from the prism. The image of *q* will then be thrown on the paper without any necessity for a lens.

The camera lucida thus described presents the objects direct, and without reversal of left and right; but it is by no means an easy instrument to use. There is what is called a knack, which some can acquire, and some cannot. It has been found of considerable use by travellers who were unable to draw from nature, but it is at best little better than a toy, and thus it has been in a great measure superseded even for unartistic travellers by the photographic camera.

CAMERA OBSCURA, the dark chamber, an instrument by means of which images of external objects are thrown upon a plane surface, or, as it is termed, focussing screen.

The earliest description of the camera obscura is in the seventeenth book of the 'Magia Naturalis' of John Baptista Porta, who directs to make a small aperture in the shutter of a perfectly dark room, and to let the light fall upon a white screen or wall. It is evident that in

Fig. 1.

this way inverted images will be obtained, the magnitude of which will depend upon the distance of the screen from the aperture. Porta makes one more step towards the present instrument. He states, as a secret which he had concealed till then, and had intended always to conceal, that if a convex glass be applied to the aperture, all external objects shall be seen as clearly as to a bystander, with so much pleasure that those who see it can never enough admire it. He does not appear to have found out that the screen should be curved, in order that the points of convergence of all the pencils should fall exactly upon it. The present form of the common camera obscura is as follows: The box in the diagram has a tubular lateral opening which should, if the lens be large, be partly closed by a diaphragm to

Fig. 2.

diminish the effective aperture. The rays passing through the lens from a distant object are prevented from converging by meeting a mirror inclined at 45° to the bottom of the box, and are thus made to converge at or very near to the glass plate *A*, one side of which is ground. A shade over the glass plate excludes direct light from falling on it. The under side of the glass plate should be curved; but, generally speaking, the aperture is so small that this is of little consequence for ordinary purposes. The tube in which the lens is placed is made to slide, so that it can be adjusted to near or distant objects. The instrument being adjusted, the landscape directly in front of the object-glass will be painted on the glass *A* and not inverted, but only the right side on the left, and *vice versa*.

A camera obscura for exhibition, such as is now most commonly seen at summer watering-places, is generally made in a room with a conical roof and an aperture at the top. Above this aperture is a revolving plane mirror inclined at 45°, and reflecting pencils downwards. A convex lens causes these pencils to converge upon a surface of plaster of Paris, properly curved. The mirror revolves about a vertical axis, thus allowing all the compass-points of a landscape to be successively thrown on the surface.

On these instruments we may observe that they are *artificial eyes*. The rays are collected by a lens or prism, and are then made to paint images upon a surface, which answers to the retina. Or conversely we may say that, in the common experiment of cutting away part of the eye of a dead animal to show the images on its retina, the eye thus employed is converted into a camera obscura.

Prior to the discovery of photography, the camera obscura was only an elegant scientific toy; but the important part it was made to

play in that beautiful art at once raised it to the rank of a philosophic instrument, and its adaptation to the peculiar requirements of the art has been a subject of continuous and careful investigation. In form, as in principle, the photographic camera differs little from that above described. But the only light admitted into the camera must pass through the lens, and the image, instead of being reflected by a mirror on to the horizontal ground-glass screen *A*, is thrown at once upon the screen itself, which is upright and corresponds to the back of the camera in *fig. 2*, or to the screen *B* in *fig. 1*. The screen (in photographic cameras called the focussing screen) is of ground glass, as in the ordinary camera; but in the practice of photography it is only used for ascertaining that the object is correctly placed and properly defined, when it is removed, and the prepared plate or paper substituted.

The great objects to be obtained in photographic cameras are, that the images shall be exhibited on the screen clearly and sharply defined: in their true forms and with their natural light and shade, on a flat plane, that is, and free from all aberration or distortion. In order to effect this, the nicest adjustment of lenses, prepared with the strictest accuracy, are employed. In practice, it is found that only achromatic combinations, in which the chemical and optical foci are coincident, will serve; and that for near objects, as portraits, and for objects which are situated in varying planes, as in landscapes, very different combinations must be used. For portraits, the usual combination is formed by two compound achromatic lenses, the two flint lenses being turned towards each other, and the convex side of the front combination towards the sitter. For landscapes, a meniscus lens, formed of a double convex lens of plate-glass cemented to a double concave lens of flint-glass, is employed, the concave side (which should be very slightly concave) being turned towards the interior of the camera. The varieties of lenses made by different opticians are, however, very great, but a description of them would be out of place here. Among the most successful are the orthoscopic, the Petzval, the aplanatic, &c.

The varieties of photographic cameras are even more numerous than of photographic lenses; but none of the varieties involve any material difference of principle. The most usual varieties are such as the folding, the expanding, and the adjusting camera, or some combination intended by the inventor to secure greater accuracy or portability, or to avoid some defect in cameras in ordinary use. For taking stereographs, however, and for copying photographs, prints, &c., on a larger or smaller scale, cameras of a special character are manufactured. The *Stereoscopic Camera* is, however, little more than a double camera, or two cameras combined in one (and hence sometimes called a double lens, or binocular camera) with adjustments for giving slight independent motion to each for rapidly covering the lenses, &c. The *Copying Camera* is a more complex apparatus; arrangements having to be provided for lengthening the body of the instrument before as well as behind the lens, altering the place of the lens, focussing-glass, camera-back, dark frame, diaphragms, &c., according to the size of the copy, whether the original is transparent or opaque, &c. Cameras intended for obtaining "instantaneous photographs," as well as for other special purposes, have also been manufactured, among which perhaps might be mentioned Mr. Skaife's ingenious 'pistol camera.' But for further particulars we must refer the reader to treatises on photography and to the articles LENS and PHOTOGRAPHY.

CAMERONIANS. [CAMERON, RICHARD, in BIOG. DIV.]

CAMOUFLET, or STIFLER, is a term applied in military mining to a small charge of powder, or undercharged mine, which makes little or no crater above ground, but by the concussion underground destroys a portion of the enemy's gallery and suffocates his miners.

CAMP. [ENCAMPMENT.]

CAMP, ROMAN. There are few parts of the art of war as practised by the Romans in which the laborious and regulated carefulness of that sagacious people is more evident than in their system of castrametation. In the present article we shall give some account of the construction of their camps, and the arrangement of the troops in them.

In speaking of the Roman camps, it is necessary to distinguish between the summer and winter encampments (*castra aestiva et hyberna*); and again to discriminate between those camps which were formed to protect the army for a short period, and those which they proposed to occupy for a longer time, which were called *castra stativa*. The difference between these consisted chiefly in the strength of the fortifications, and in the superior size of the temporary camps, which were intended commonly for the whole army, while the more permanent encampments were for divisions of the army. Winter encampments were not used by the Romans in the earlier periods of their history, when their chief wars were little more than summer campaigns, and were waged against neighbouring nations: but in a later age, when permanent conquest was their aim, and the war continued several years, the army was regularly distributed into winter-quarters, and often spread over a considerable extent of country, in order to overawe the subjugated districts, or because forage and provisions could be obtained by the army in several divisions more easily than when it was in one body. Caesar in his Gallic campaigns regularly distributed his army into winter-stations, so strongly fortified that though several attempts were made upon them only one was taken, and that because the commander unwisely abandoned it. (Caes. 'De Bel. Gal.' lib. v.)

Perhaps the completest description which we have of a Roman camp may be found in Polybius, who has in the sixth book of his history given a pretty full account of the military tactics of the Romans, part of which, relating to their castrametation, we shall condense with the further information collected by General Roy. Polybius lived at a time when the institutions of the Republic were in their full vigour; he had gained military experience in the armies of his country; and his opportunities of acquiring information, both from personal observation and from the information of others, were ample. The Roman

legion, we may remark, in the time of Polybius consisted of 4200 infantry (or in time of peculiar emergency 5000 infantry) and 300 cavalry. The Consular army was formed of two legions; with a body of allied foot, equal in number to the infantry of the legions, besides the extraordinaries, chosen troops of the allies, who probably amounted to 2100, or when the legion was of 5000 infantry, to 2500; and of allied horse, thrice the number of the legionary cavalry; of these allied horse one-third were drafted for the extraordinaries, making the total of the Consular army 18,900, or 22,500 infantry and 2400 horse.

PLAN OF THE POLYBIAN CAMP OF A ROMAN CONSULAR ARMY.

The *Prætorian*, or *Quæstorian* Gate.

When a place suitable for a camp had been chosen,—and the choice of a suitable spot was regarded as a very important part of the commander's duty,—the first thing was to fix a standard on the spot judged to be most adapted for overlooking the army when encamped, and sending commands to the different quarters. Round this standard a square of 200 feet was measured, and set apart for the general's quarters: this was called *prætorium* (A), from the name *prætor*, which, according to early Roman usage, was the general title of a military commander. On that side of this square inclosure which was deemed most suitable for obtaining forage and water, the bulk of the army was encamped, and that side of the *prætorium* and the corresponding side of the camp, we shall follow Polybius in calling 'the front.' In front then of the *prætorium*, distant from it fifty feet, on a line running across the camp, were placed the tents and baggage of the legionary tribunes (BB), who in the ordinary consular army (of two Roman legions with the regular proportion of allies, as already explained) amounted to twelve: and towards either extremity of the same line were the tents of the *præfecti* (CC) or officers, who held among the allies a rank similar to that of the tribunes in the legions. These tents were pitched with their backs to the *prætorium*.

In front of the tribunes' tents, a passage, 100 feet wide, called in our plan the *Principia*, or *principal street* (D D), ran across the camp; and between the side of this passage and a line parallel to it, near the front of the camp, the soldiers were encamped in lines, which formed a right angle with the *Principia*. The soldiers' quarters were divided into two parts by a passage 50 feet wide (E), which ran from the *prætorium* to the front of the camp. On each side of this street were posted the Roman cavalry, and next to them the *Triarii*, one of the divisions of the legionary infantry. Next to these were two passages of 50 feet wide (F F F F), and then the *Principes* and the *Hastati*, the other divisions of the Roman infantry. The tents of each division fronted the passage next to them, so that when the tents of two divisions, as of the cavalry and the *Triarii*, and of the *Principes* and the *Hastati*, were not separated by an intervening passage, they had their backs to each other. There were in a legion ten *turmæ* of the cavalry, and ten *manipuli* of each division of the infantry; and the *turmæ* and *manipuli* of each division were encamped in one range along the passages, a quadrangular space of 100 feet square being allotted to each *turma* of cavalry, and each *manipulus* of the *Principes* and *Hastati*, while each *manipulus* of the *Triarii*, which had seldom more than half the complement of the other *manipuli*, had a space of 100 feet by 50.

Beyond the tents of the *Hastati* on each side was another passage of 50 feet wide (G G G G), and then came the quarters of the allied cavalry, and beyond these again, without any separating passage, the quarters of the allied infantry, whose tents looked toward the ramparts of the sides of the camp. The tents of the allies occupied a space of the same length as that occupied by the legionary soldiers. The depth of their quarters varied with the number of the men: our plan assigns to the cavalry and infantry an equal depth, namely, of 200 feet each; this is probably near the truth. The quarters of the legionary soldiers and the allies were alike divided into two parts by a passage 50 feet wide, called *quintana* (H H), running across the camp in a direction parallel to that of the *Principia*, between the fifth and sixth manipuli and *turmæ*.

The space on each side of the *prætorium* was occupied, the one side (K) by the *questor* (whose office combined the direction of the commissariat department and the care of the military chest) and the military stores, and the other side (M) by the *forum*, or place for holding a market and transacting business. Next to these on each side were the quarters (N N) of the chosen troops from the extraordinary cavalry of the allies, who served in the consul's body-guard, and of the volunteers (O O) who had engaged in the service from regard to the consul. The tents of these looked towards the *questor's* quarters and the *forum*. Beyond these on each side, with their tents fronting the rampart of the camp, were the chosen troops (Q Q) from the 'extraordinary' infantry of the allies, who also formed part of the consul's body-guard. Behind all these, right across the camp, ran a passage or street of 100 feet wide (P P); and beyond this passage, and parallel to it, were the quarters of the main body of the 'extraordinary' cavalry of the allies (R R); and behind these, looking towards the back of the camp, were the quarters of the extraordinary foot of the allies (S S). The flanks of these quarters (T T) were occupied by any foreigners or temporary reinforcements of allied troops which might be in the camp. Polybius does not assign any particular quarters to the *velites*, or light armed men.

The space occupied by all these quarters formed a square, and on every side was left an interval of 200 feet, which served for various useful purposes, to deposit the booty, to afford space for the troops to enter and leave their respective quarters, and to protect the tents and troops from fire or weapons thrown by any who might assail the camp from without. The whole was surrounded by a rampart (*vallum*) and a ditch (*fossa*), through which were four gates or entrances: the *Prætorian gate* (*Porta Prætoria*), in front of the camp, opposite the *prætorium*; the *Decuman gate* (*Porta Decumana*), at the back of the camp; and a gate at each end of the *principia* or principal street.

If the two consular armies were united, the camp formed an oblong square, and resembled two camps placed back to back, without any intervening intrenchment. It appears to have had six gates, two *prætorian* and four others, one at each end of the two principal streets or passages.

The *vallum* was composed usually of earth or turf, sometimes of stones or wood, and was surmounted by a palisade. The ditch was on the outside. In stations which were designed to be permanent, and which were in a disturbed or hostile country, the works were constructed with unusual care, and there are many remains or vestiges of them in different parts of Great Britain. Among the most perfect are those at Ardoch, in Scotland, and Llandrindod in Wales.

The plan of a Roman camp, which we have given, is taken from General Roy's 'Military Antiquities of the Romans in Britain,' to which, and to G. F. Rettig's 'Polybii Castrorum Romanorum formæ interpretatio,' we refer the reader for many valuable observations on the castrametation of the Romans.

CAMP-SHEETING. An enclosure at the foot of a wall or quay, carried down to the water's edge, for the purpose of limiting the vertical compression of the ground. Camp-sheeting differs from sheet, or close, piling in this respect, that although it is executed with guide piles, whales, and sheeting, all its parts are essentially of small dimensions. It is, in fact, a diminutive sheet piling, in which the total length of the sheeting above and below ground does not exceed ten feet. Sometimes the sheeting of this description of enclosure is laid horizontally, and is spiked at the back of the guide piles which, under these circumstances, are kept very close together.

CAMPANILE, an Italian term, signifying a tower for bells. The word is derived from *campana*, "a bell." In many respects the campanile corresponds with the belfry or steeple of the Gothic churches of the North; but the term is usually and very conveniently confined to the Italian bell-towers, which differ from those of the North in being of equal dimensions from the base to the summit, constructed without buttresses, and for the most part terminated without a spire.

The campanile is essentially an Italian structure. It has no prototype in classic architecture; and, when copied even by Romanesque architects beyond the Alps, it was with a difference. Usually, the Italian campanile belongs to a church, if it does not form a part of one; but many, though attached to churches, are civic structures, as that of St. Mark at Venice, and the well-known leaning tower at Pisa; while others, like the Asinelli and Garisenda towers at Bologna, and that of the town-hall, Florence, are entirely municipal in purpose. Very frequently the campanile stands wholly detached from the church to which it belongs, but more commonly it is attached to an angle of the building. Originally the campanile was constructed with a plain solid base,

pierced only with small windows for two-thirds of its height; the upper story or stories having one, two, or more, larger round-headed windows, or an open loggia. Of this kind is the campanile of St. Mark, already alluded to, which was begun in 992, and is one of the oldest campanili left; the heavy upper story is of more recent date. With the introduction of the pointed arch, more of lightness and ornament was imparted to the upper part of these structures, they were more distinctly divided into stories, and they were crowned with a cornice or surmounted with a spire; but the square form was retained, and they remained uniform in size and without buttresses. Sometimes the spires were made octagonal at the base, and much enriched in the lower part; but they seldom harmonise well with the tower, and usually they are of no great elevation, and not remarkable for elegance of outline. Among the most remarkable Italian campanili are those of Cremona, Florence, Ravenna, Padua, Modena, Mantua, Sienna, Bologna, Pavia, Verona, and Pisa.

Some of these campanili are much out of the perpendicular, especially those of Pisa and Bologna. The Garisenda, built by the Garisendi, at Bologna, is 153 feet high, and 8 feet 6 inches out of the perpendicular. Dante has compared this tower to the inclined figure of Antæus. (Dante, 'Inf.' canto xxxi. l. 135.) The Asinelli tower, also at Bologna, and close to the former, is 320 feet high, and 3 feet 6 inches out of the perpendicular. The leaning tower at Pisa is 150 feet high, and 13 feet out of the perpendicular. The campanile of Cremona is the highest in Italy, having an elevation of 395 feet.

The most remarkable, and in many respects the finest of the Italian campanili, is that of Florence, which is 269 feet high, and was constructed by Giotto in 1324. The plan is a perfect square, 45 feet on each side. The interior is divided into six floors, each of which is vaulted. The tower is ascended by 406 steps. The façade of the tower is Gothic in style, but mixed with somewhat of the Italian taste in architecture, which soon after prevailed over the Gothic. In the cut, the window-shafts appear plain, but in reality they are twisted; and the whole façade is covered with ornament. It is said that Giotto intended to surmount this tower with a spire 85 feet in height. The surface is veneered with coloured marble, which, though structurally objectionable, adds greatly to the richness of its appearance. Among transalpine towers bearing a marked resemblance to those of Italy, one of the most interesting is that of the cathedral at Seville, which is 350 feet high. It is said to have been begun by Abu Yusuf Yacub, in 1196, famous for other great architectural works, and is therefore contemporaneous with some of the most celebrated Italian towers. This tower is called La Giralda, or Girandillo, from a bronze female figure bearing that name; this figure, though it weighs a ton and a half, turns with the wind; it was cast in 1568, and replaced the four brazen balls which formed the original Moorish termination, but which were thrown down in 1395. (Gailhabaud; Street; P'Anson; Fergusson.)

Wren, in his church towers, without actually copying Italian campanili, worked much in the spirit of their designers, and produced picturesque structures. Within the last few years, campanili of Italian form have been attached in this country to some churches and chapels built in the Romanesque and pointed Italian styles; and to some Italian renaissance town-halls, corn-exchanges, &c.; and they seem to form a favourite type with architects and civil engineers in constructing chimney-shafts. (See Rawlinson on 'Chimney-Shafts'.)

[Campanile of the Cathedral at Florence, designed and built by Giotto.]

CAMPHEN. [TURPENTINE.]

CAMPHILENE. [TURPENTINE.]

CAMPHINE. [TURPENTINE.]

CAMPHOCREOSOTE. *Carvacrol*, *Carnacrol* ($C_{20}H_{14}O_2$). A colourless, oily body obtained 1st, by acting upon oil of carraway with potash; 2nd, by treating the same oil with glacial phosphoric acid; 3rd, by treating the oil with iodine; and 4th, by acting upon laurel camphor with iodine. The following is probably the reaction in the latter case:—

Camphocresote boils at 449° Fahr., is lighter than, and almost insoluble in water, possesses a disagreeable odour and a persistently bitter taste. It burns with a bright smoky flame.

CAMPHOETHYLIC ACID. [CAMPHOR.]

CAMPHOGEN ($C_{20}H_{14}$), *Cymene*. This substance is obtained when common camphor ($C_{20}H_{16}O_2$) is distilled with dry phosphoric acid. It is found also in the oil of cumin. It forms with sulphuric acid a compound called sulphocamphic or hyposulphocamphic acid, $C_{20}H_{15}S_2O_5 + HO$. [CAMPHOR.]

CAMPHOLENE. [CAMPHOR.]

CAMPHOLIC ACID. [CAMPHOR.]

CAMPHOLONE. [CAMPHOR.]

CAMPHOMETHYLIC ACID. [CAMPHOR.]

CAMPBOR is the stearopten, or one of the principles arising from the separation of the volatile oil of two trees; the one, *Cinnamomum camphora* (Nees v. Esenbeck), a native of Japan, China, and Cochin China, yields common or laurel camphor; the other, *Dipterocarpus camphora*, or *Dryobalanops camphora* (Colebrooke), a native of Borneo and Sumatra, called Sumatra or Borneo camphor. From these it is procured by different processes. It exists in every part, root, stem, branches, and leaves, of the first-mentioned tree, which is chopped into pieces sufficiently small to be thrown into iron vessels: these vessels are afterwards covered with earthen hoods, in which are placed rice-straw and rushes, heat being subsequently gradually applied. The camphor is volatilised, and afterwards condenses on the straw, rushes, &c. This, after being purified from the intermixture of straws, is found in commerce under the name of crude camphor, distinguished into Japan or Dutch camphor, and China or Formosa camphor. But it still retains many impurities, and on arrival in Europe is refined, formerly exclusively at Venice, now also in England, Germany, and Holland.

From the *Dipterocarpus camphora* it is not procured by distillation, but exists in a solid form in the stem of the tree. In that part of the stem which should be occupied by the pith it is found, along with camphor-oil. When tapped or opened while young nothing but oil flows, but in time a great quantity of this oil assumes the solid form, and is found at intervals along the trunk in pieces a foot or a foot and a half long. The process of extracting the oil is effected by means of a Malay axe used to lay open the trunk at about eighteen inches from the ground, till near the heart, when a small incision is cautiously made, and the oil, if present, gushes out, and is received into bamboos and other vessels. If camphor is suspected to be present the tree is felled, cut into pieces about a fathom long, which are then split, and the camphor is found in pieces of the length stated, and about the circumference of the human arm. A tree of moderate size may yield about eleven pounds, while a very large one may produce twice that quantity. The camphor so obtained is called *Se Tantong* or head camphor; but the wood which surrounds the camphor on being scraped yields an inferior sort, called belly and foot camphor. The camphor from this tree is much less volatile and transparent than from the former. It is slower in its effects, but these are more permanent.

The oil is much prized and used in the East, but is not sent to Europe. So much more is the Borneo and Sumatra camphor esteemed than the other, that even in the markets of Japan seventy-eight pounds of the camphor of the latter country will be given in exchange for one pound of the former. The Bornean camphor is white, like chalk, but has the same smell and taste as that of Japan.

The process of refining consists in exposing the camphor in large ovens in flat glass baskets, along with a little charcoal, caustic lime, or chalk, during which the Sumatra camphor diffuses an odour like violets. Refined camphor is in round cakes, convex externally, concave internally, generally with a hole in the centre, each weighing about two pounds: the cakes are wrapped in strong blue paper, and exported in packages weighing about 500 pounds, containing 250 or 251 cakes.

Camphor is an organic substance of a peculiar kind, representing the volatile oils in a solid state. It differs from them, however, not only in being solid at the ordinary temperature of the air, but in not being converted by the oxygen of the air into a resin. It is so volatile that on exposure to the air it is entirely volatilised, and leaves no residuum. It has an unctuous feel, possesses considerable tenacity, and is not easily powdered, without the addition of alcohol, ether, or oil: the Sumatra camphor, however, can be powdered without such aid. It is nearly insoluble in water (requiring 1000 parts for its solution), but very soluble in alcohol, the ethers, eupion, creosote, the empyreumatic,

volatile, and fixed oils. It is precipitated from most of its solutions, in an unchanged state, on the addition of water. Its specific gravity is 0.985; its ultimate composition is, according to Blanchet and Sell,

Carbon	79.28
Hydrogen	10.34
Oxygen	10.37

At 347° of Fahrenheit's thermometer it melts, at 400° it boils; it is easily ignited, burning with a bright flame and much smoke, but leaving no residuum. Its odour is strong and peculiar, its taste aromatic and bitterish, leaving behind it a feeling of coldness in the mouth.

Camphor acts upon the animal frame, both in the state of vapour and in the solid state. Few insects can endure the pungent odour of camphor; and in combination with strong acetic acid it acts as a powerful stimulant in cases of a disposition to fainting. When six or eight grains are received into a stomach in which there exists no increased sensibility, the person also not being in a state of excitement, the first effect is a feeling of burning and warmth, which gradually extends from the epigastrium over the whole body, occasionally accompanied with unpleasant feelings in the stomach, such as slight pain, eructations, &c. The pulse soon rises, becomes fuller and undulating; the heat of the skin is gently increased, and a warm and gentle but regular perspiration follows. All muscular actions take place with more ease; the nervous system in its whole range is roused and strengthened, and a feeling of general comfort pervades the whole frame. In from one to three hours this state abates, without leaving sleepiness, lassitude, or any unpleasantness behind.

A larger dose, half a drachm or two scruples, causes a burning heat in the palate and stomach, with pain, disposition to vomit, and great disturbance of the nervous system (the severity of which is determined by the amount of action on the stomach), giddiness, sense of constriction in the head, ringing of the ears, flickering of objects before the eyes, errors of vision, tremblings of the limbs, and impossibility of maintaining the erect posture, or of walking. During the continuation of this state, shiverings, with paleness of the skin and countenance, diminished warmth of skin, a slow, feeble, and contracted pulse, a laborious respiration, and threatenings of faintings or convulsions exist. When death results, the stomach is discovered to have been the seat of violent inflammation. Camphor may therefore be regarded as a powerful stimulant, at first local, but afterwards extending to the brain, spinal chord, and ganglionic system.

It is used in the low or sinking stage of almost all fevers, particularly where the nervous system is much depressed. At an earlier stage of the same disease, along with antimonials or opium, it often has a very beneficial effect on the skin, promoting regular and warm perspiration. It has also been used along with nitrate of potassa during the interval of an intermittent fever, to prevent a return of the paroxysm. In exanthematous fevers, such as small-pox, measles, scarlet fever, &c., it is often very serviceable during the eruptive stage, when the eruption does not come out freely, from want of sufficient nervous energy. In such circumstances, along with serpentaria, it is superior to any other means.

In chronic nervous diseases, such as cramps, tendency to convulsions of certain kinds, epilepsy, St. Vitus's dance, and similar disorders, it is often a valuable agent or vehicle for other remedies. Its external application as a rubefacient, in cases of cramps and neuralgic pains, is often of great service. The compound camphor liniment, which is a solution of camphor in volatile oil of lavender, alcohol, and ammonia, is an excellent solvent for iodide of potass, furnishing a valuable rubefacient. Combined with extract or tincture of hyoscyamus it procures sleep in cases of nervous restlessness.

In many cases of irritability of the urinary organs it is useful.

It is administered either in powder, in which case it must be minutely divided and mixed with other substances, or in aqueous solution (a very feeble preparation, though it possesses the odour), or alcoholic solution. When it is dissolved in oil, it forms a useful application to joints and other parts suffering from chronic rheumatic pains.

The use of camphor in the form of vapour from a bag carried round the neck, as a prophylactic during the prevalence of epidemic fevers, is hurtful. It produces depression of the nervous power, muscular debility, difficulty of respiration, and favours the very action of the morbid agent which it was intended to prevent. Its employment even in museums to protect the objects from insects, and among clothes to ward off moths, is injurious, if much be volatilised and diffused through the apartments; besides insects of the section *Tinea*, which chiefly destroy wood, are not affected by it.

Camphor exists in several plants and trees besides those above mentioned; and a substance resembling camphor, and generally considered to be such, can be procured from many plants. It is in most cases, however, a hydrate of volatile oil, such as the Coumarin or odorous principle of the Tonka bean, Helenin from the *Inula Helenium*. An artificial camphor may be prepared by the mutual action of hydrochloric acid gas and oil of turpentine: it is white, possesses a camphor-like odour, is soluble in alcohol, &c.

Artificial camphor does not produce the lesion of the nervous system which is caused by ordinary camphor. It is therefore im-

portant to distinguish them. Artificial camphor, when heated, gives off the odour of turpentine, and, when ignited, burns with a sooty flame. The action of polarised light also serves to distinguish them. According to Mr. Bailey, if a fragment be placed on a microscopic slide, and a drop of alcohol added, it will first dissolve, and re-crystallise as the spirit evaporates. Examining this with the aid of a polarised light, the crystals of true camphor will seem as if beautifully coloured; but not so those of the artificial product.

CAMPOR ($C_{20}H_{16}O_2$). Ordinary commercial, or laurel camphor, is a product of the *Laurus camphora*, a tree growing abundantly in China and Japan. The following is the method of extraction adopted in the latter country. The roots and wood of the tree are cut up and boiled with water in large pans fitted with heads in which are placed reeds or rice straw; on these the camphor condenses, being carried up by the steam. In China, the chopped wood is steeped in water, and boiled till camphor adheres to the stirrer, the liquid is then strained off, and on standing the camphor separates out. Obtained by either method it requires purification, and this is an operation extensively practised in England. It consists in mixing the camphor with lime, and heating on a sand-bath in thin glass vessels of the shape of an onion, about a foot in diameter, called bomboloes. As the temperature rises the camphor fuses, boils and condenses in the upper part of the vessel; at the end of the operation these are cracked by sprinkling with cold water, and the hemispherical cakes taken out and trimmed. They usually weigh from ten to twelve pounds.

Camphor obtained by sublimation, or from solution in alcohol, crystallises in octohedra or segments of the same; white, brilliant, and almost as transparent as glass. Specific gravity .986 to .996, according to temperature. It has a pungent bitter taste, and peculiar aromatic odour. It slowly evaporates at common temperatures, condensing in beautiful plates on the sides of the vessel in which it is contained. Light seems to favour this evaporation; it takes place most rapidly when camphor is in contact with water, and gives rise to those peculiar gyratory movements which are observed when small pieces are thrown on to the surface of that liquid. Camphor is tough, and difficult to powder, unless slightly moistened with alcohol, when the operation becomes an easy one. Heated, camphor fuses at 347° , boils at 399° , and distils without decomposition. Its vapour density is 5.317. It dissolves in one thousand times its weight of water, forming the camphor-water, mixture, or julep, of pharmacy. It is very soluble in alcohol, ether, acetic acid, fixed and volatile oils, chloroform, and bisulphide of carbon. Alkaline solutions seem to have but little action on it. It absorbs variable quantities of hydrochloric acid, sulphurous acid, and hyponitrous acid gases, oily bodies being formed, from which water separates the camphor unchanged. Heated with anhydrous phosphoric acid, fused chloride of zinc, or concentrated sulphuric acid, it yields *cymène* ($C_{10}H_{14}$) (camphogen) and water. Left in contact with excess of sulphuric acid for some days, it yields, on diluting the mixture with water, an oily body, colourless when pure, and having the same composition and state of condensation as solid camphor: it is changed into the latter by caustic potash. Chlorine acts slowly upon camphor, giving rise to unstable products, in which that element replaces hydrogen in variable quantities. Bromine forms with it a crystallisable substance ($C_{20}H_{16}O_2Br_2$). Iodine acts more energetically, giving rise to several compounds. Perchloride of phosphorus decomposes it, forming a body closely resembling artificial camphor; perchloride of antimony also strongly attacks it.

Camphrone, is the name given by M. Frémy to a liquid, obtained by passing the vapour of camphor over red-hot lime. Boiling point 167° .

Campholic acid ($C_{20}H_{18}O_4$), is formed by subjecting camphor and hydrate of potash to heat under pressure.

It may be isolated by precipitating with an acid an aqueous solution of the resulting salt. It is insoluble in water. Heated, it fuses at 176° , and at about 482° boils and evaporates without decomposition. Its vapour density is 6.058. It is a monobasic acid. The lime salt ($C_{20}H_{17}CaO_4$) is formed by adding chloride of calcium to a hot solution of campholic acid in excess of ammonia: it is a crystalline powder.

Campholone ($C_{33}H_{34}O_2$) is a product of the dry distillation of campholate of lime.

Campholene ($C_{18}H_{16}$) is a liquid hydrocarbon, obtained by distilling campholic acid with anhydrous phosphoric acid.

Camphoric acid ($C_{20}H_{14}O_6, 2HO$) results from the action of boiling concentrated nitric acid upon camphor till no more red fumes are evolved. It crystallises out on cooling, and may be freed from any undecomposed camphor by dissolving in solution of carbonate of potash, precipitating with nitric acid, and re-crystallising from water. The crystals are either lamellar or acicular; they have a sour and somewhat bitter taste, Melting point 158° . This acid is but slightly soluble in cold water, more so when boiled; alcohol, ether, and the fixed and essential oils dissolve it with facility.

Camphoric acid unites with salifiable bases to form salts called *camphorates*. Not one of them is applied to any purpose whatever. Those which are soluble have almost all of them an aromatic bitter taste; the aqueous solutions are decomposed by the stronger acids, and they all burn and are decomposed by heat.

Anhydrous camphoric acid ($C_{20}H_{14}O_6$) is produced by distilling the hydrated acid, water being separated at the same time. The sublimate may be obtained in prisms of considerable length, by re-crystallisation from boiling alcohol. They are nearly tasteless, but after a time produce considerable irritation in the throat. Water dissolves them in small quantity. In ether they dissolve readily. Heated to 266° they begin to sublime in beautiful needles, at about 423° fuse into a colourless liquid, and boiling at 518° , distil over without undergoing decomposition. Anhydrous camphoric acid may be digested with hot water for two or three hours, without combination taking place; continued ebullition however ultimately determines the formation of the hydrate. The former does not precipitate neutral acetate of lead, the latter does so abundantly.

Camphoric acid is bibasic, and forms well defined salts with nearly all the bases. General formula ($C_{20}H_{14}M_2O_8$). They are for the most part crystallisable, soluble in water, and decomposed by the stronger acids.

Sulphocamphoric acid ($C_{18}H_{16}S_2O_{12} + 4Aq$). When anhydrous camphoric acid is heated with fuming sulphuric acid, carbonic oxide escapes, and from the solution diluted with water, filtered through asbestos and exposed in vacuo, the sulpho-acid crystallises out. It may be purified by solution in, and recrystallisation from, alcohol.

The crystals are colourless, bitter, soluble in water, alcohol, and ether. Exposed in a vacuum they lose four atoms of water. Between 320° and 330° they fuse and soon begin to decompose. They are dissolved by boiling nitric acid without decomposition. Sulpho-camphoric acid is bibasic, the neutral salts having the formula $C_{18}H_{16}M_2S_2O_{12}$.

Campho-methylic acid or *methyl-camphoric acid* ($C_{20}H_{15}(C_2H_5)O_8$), and *Campho-ethylc* or *ethyl-camphoric* or *camphovinic acid* ($C_{20}H_{15}(C_4H_5)O_8$), may be represented as camphoric acid in which an equivalent of hydrogen is replaced by the radicals methyl and ethyl respectively. They are obtained by digesting together for some time a boiling mixture of camphoric and sulphuric acids with the respective alcohols, namely, wood spirit and spirit of wine: on diluting with water they separate out. Both are colourless. Methyl-camphoric acid occurs in acicular crystals. Ethyl-camphoric acid is a thick oily body. They form salts with most of the bases.

Camphoric ether or *camphorate of ethyl* ($C_{20}H_{14}(C_4H_5)_2O_8$) results from the dry distillation of ethyl-camphoric acid according to the following equation:

Chlorine attacks this body, giving rise to camphorate of bichlorethyl ($C_{20}H_{14}(C_4H_3Cl_2)_2O_8$).

Camphoramie acid ($C_{20}H_{17}NO_6$) is obtained, combined with ammonia, on passing dry ammoniacal gas through an alcoholic solution of anhydrous camphoric acid; on adding dilute hydrochloric acid and evaporating, it crystallises out. When the crystallisation of this acid from a hot aqueous solution is seen through a microscope it presents a very beautiful appearance.

Camphoramide ($C_{20}H_{15}N_2O_4$) is prepared by passing a current of ammoniacal gas into a solution of anhydrous camphoric acid in absolute alcohol. On evaporation the camphoramide is left as a syrupy matter insoluble in water.

Camphorimide ($C_{20}H_{15}NO_4$). When camphoramie acid is heated to a few degrees above 300° , water is evolved, and camphorimide remains. It may be crystallised from solution in boiling alcohol.

Camphoranilic acid or *phenyl-camphoramie acid* ($C_{20}H_{16}(C_{12}H_5)NO_6$), as will be seen from the formula, differs from camphoramie acid in containing an equivalent of the radical phenyl ($C_{12}H_5$) in the place of an equivalent of hydrogen.

Camphoranile or *phenyl-camphorimide* ($C_{20}H_{14}(C_{12}H_5)NO_4$) bears a similar relation to camphorimide. Both the foregoing anilides are produced when a mixture of anhydrous camphoric acid and aniline is heated; they may be separated by digesting in solution of ammonia, when the phenyl-camphoramie acid dissolves and the phenyl-camphorimide remains insoluble.

A variety of camphor ($C_{20}H_{18}O_2$) called by Gerhard *borneol*, and more generally known as *Borneo* or *Sumatra camphor*, is found in the crevices of the wood of the *Dryobalanops aromatica*, a noble tree growing in those islands. The old trees are cut down, split to pieces, and the little grains of camphor picked out by hand. The yield of one tree is generally very small, and but little of this variety is sent to Europe. It differs somewhat in its chemical and physical characters from ordinary or laurel camphor. As shown by the formula it contains two additional equivalents of hydrogen; its melting point and

boiling point are both higher, and when treated with anhydrous phosphoric acid it yields, as might be expected from its composition, *bornéene* ($C_{20}H_{16}$), instead of *cymène* ($C_{20}H_{14}$), obtained under the same circumstances from laurel camphor. The crystals also have a different form, are harder, and more brittle. In other respects it resembles the common camphor.

Camphor oil, or liquid camphor, is obtained from the young trees of *Dryobalanops aromatica*, by incising the bark. It is a mixture in variable proportions, of the hydrocarbon *bornéene* with borneol or solid Borneo camphor.

Camphor exists in small quantity in many plants, more especially in those of the natural order *Labiatae*; for example, lavender, rosemary, sage, &c.

The various kinds, though they may be otherwise identical, act very unequally upon polarised light. Ordinary camphor causes the rays to rotate to the right hand: Borneo camphor does the same, but more powerfully, while that obtained from the *Matricaria parthenium*, a plant of the natural order *Compositae*, and a species of chamomile (common feverfew), causes them to rotate to the left-hand. Camphor from the *Labiatae* has no action whatever on the polarised rays. Camphoric acid also causes rotation in a direction similar to that induced by the camphor that yields it. For instance, the acid obtained from laurel camphor possesses dextro-rotation, while a solution of the camphoric acid of the *matricaria* camphor, exhibits levo-rotation. A mixture of the two has no rotatory power, thus bearing an interesting resemblance to the different isomeric modifications of tartaric acid.

Besides its position in the *Materia Medica*, camphor is used to some extent as a perfume.

CANADA BALSAM. [BALSAM.]

CANAL. A word used by modern engineers to express, in an exclusive sense, the bodies of water and the works provided for the purpose of forming artificial navigable courses; the word *channel* being applied to the ordinary water-courses; *conduit*, to the artificial water-courses established for the distribution of that fluid for municipal consumption. Canals are also formed for the purposes of Irrigation [IRRIGATION]; but in speaking of them it is customary to prefix the specific title, and always to distinguish them as Irrigation Canals.

The execution of works for the purposes of improving the existing internal navigation of rivers, or for creating artificial courses for that purpose, dates from the very earliest antiquity; and it may also be observed to have taken place amongst nations whose civilisation has remained, in all other respects, in a very rudimentary state. Thus the Assyrians, Egyptians, and Hindoos, have from time immemorial boasted of the works executed by their governments, for both irrigation and navigation. The canals of China have long been famous, and indeed some of the details of Chinese construction, as their rolling bridges for instance, have served as models for Europeans; whilst the hydraulic works of the Mexicans and Peruvians justly excited the admiration of their Spanish conquerors; who, by the way, must have been acquainted with the first steps in the history of Italian hydraulic engineering, which took place precisely in the dominions of the house of Austria, near Milan. The formation of the canal de la Martes-anna was, indeed, the first great advance made by European engineers in this branch of engineering, and it was there that Leonardo da Vinci for the first time, introduced the use of locks to regulate the level of the water in different reaches of the canal. About 1642, the canal de Briare, in the centre of France, was formed, under the patronage of Sully; in 1681 the first summit level canal between two oceans was opened by means of the Canal du Midi; in England, the navigation of the Itchin, between Winchester and Southampton, was opened about the same period, but it was not until nearly a century later that the execution of our lines of internal navigation assumed, under the guidance of such men as Brindley, Smeaton, Telford, Rennie, &c., the commercial and political importance they now possess. In the following notice, however, it is not proposed to follow the historical development of the system of canal navigation; but rather to trace broadly the principles which regulate the practice of the best engineers, illustrating them with references to the most celebrated works in various countries.

Canals for the purposes of artificial navigation are of three principal descriptions, according to the nature of the locality in which they are formed, and to the immediate objects they are designed to effect. There are canals established for the avowed object of allowing sea-going vessels to proceed to towns situated at some distance from the

coast, which are known as *ship canals*. There are *lateral canals*, or those established on the banks of rivers, in order to obviate the natural obstacles to a barge navigation, whether occasioned by the irregularities in the volume of water flowing in the natural channel, or by the occurrence of rapids, falls, or other interferences with the flow of water, or with the regularity of the river's bed; sometimes also, lateral canals are formed in order to cut off the bends of the natural water courses. Lastly, there are the *junction, or summit level canals*, or those established for the purpose of connecting existing lines of navigation on the respective sides of a central elevated district dividing the water-sheds of a country. Many of the operations required for these various descriptions of canals are common to them all; but each of them presents distinctive features which render it necessary to consider them in detail.

Ship canals, being designed to accommodate vessels used for deep-sea navigation, must naturally be made of much larger dimensions than the canals exclusively devoted to purposes of inland navigation. Thus, the canal from the Severn to Gloucester has a width of 70 feet, and a depth of 18 feet, and it is able to receive vessels of 400 tons burden; the ship canal opened between Caen and the sea, has a clear width on the water-line of 100 feet, and is also intended to be used by sailing vessels of 400 tons burden; whilst the great North Holland canal, between Amsterdam and the Nieuw-diep, is not less than 124½ ft. wide on the water line, with a depth of 20 ft. 9 in., and is able to receive sailing vessels of about 1400 tons burden. The dimensions of the Caledonian canal are 115 ft. 6 in. on the water line,

Caledonian Canal.

and 20 ft. depth of water. Some of the lateral canals, however, have widths upon the water line as great as those above quoted; but in no case is their depth made to exceed, in any notable manner, about 8 feet; and the construction of the locks, and of the entrances to the tidal basins, is the most materially affected by this condition.

In forming a ship canal, great care is required in the selection of the position of the entrance from the sea, in order to secure free access at all times of the tide, and a permanent depth of water in the outer harbour. The entrance must, in fact, be placed in a sheltered roadstead, and in such a position as shall ensure its immunity from the action of any littoral current able to transport much alluvial matter; at the same time there must theoretically be a sufficient supply of clear water to allow of an efficient scour in the harbour. It is also essential that the direction of the entrance should be such as to obviate any possible inconvenience from the prevailing winds, so far as the entry of ships into the harbour, or their departure thencefrom, is concerned. By the application of a good system of dredging, and even by creating an artificial scour, it is possible to correct any natural tendency of a harbour to become silted up; but there are no simple artificial means by which the dangers resulting from a harbour's being exposed to the direct action of a head sea can be obviated; so that, after all, the exposition of the entrance to a ship canal, with reference to the position of the prevailing winds, is the most essential point to be considered in its selection. If, therefore, the outlet of such a canal to the sea should be situated upon an exposed coast, it will be necessary to form an outer harbour; and to establish the entrance locks to the artificial navigation under the shelter of the jetties or piers thus carried forward. When the entrance is, however, situated in a protected position, it must be designed upon the same principles with reference to the set of the currents, and to the facilities to be given to the passage from the canal to the open navigation, which will hereafter be described in the case of ordinary canal entrances.

The lock gates of ship canals are necessarily of much larger dimensions than those of either of the other description of canals; for not only are the vessels they are required to pass larger than the ordinary river or canal craft, but they often require to resist greater differences of level on their upper or lower sides, in consequence of the rise and fall of the tides. On the Caledonian canal, the clear width of the lock chambers, at the level of the coping is 40 ft.; and a gate intended to pass a 1400 ton vessel must be at least 50 ft. wide at the narrowest part; and whereas, ordinary canal locks are made to overcome differences of level of 8 ft., it may often happen that the difference of level between the inner basin and the outer tidal surface of the entrance harbour of a ship canal, may attain as much as from 24 to 30 feet in height. In the North Holland canal the engineers have very wisely constructed the locks with two passages, one for large vessels, the other for small ones; thus obviating the necessity for wasting the time and water required to fill the large lock when a smaller one would suffice, and also, avoiding the unnecessary fatigue of the large gates. The mode of constructing lock gates, and the precautions to be taken to prevent their change of form, are described in the subsequent part of this article under the sub-head, *Locks*.

In ship canals it is desirable to form towing-paths on both sides, so as to be able to keep a ship steady during the prevalence of high winds; and it is customary to leave a narrow zone of shallow water on the banks of either of the towing-paths, for the purpose of destroying the effect of any waves in the canal upon the banks. The towing-paths themselves are finished at a minimum elevation of about 3 ft. 3 in. above the water line in the best canals of this description. The other works upon ship canals, so far as regards the provisions to be made to counteract interferences with the local drainage, or with the ordinary water courses of the district, are so precisely analogous to those required upon other lines of navigation, that they will be considered simultaneously with the latter.

Lateral canals are established, as was before stated, in almost all cases for the purpose of obviating the natural causes of disturbance in the river navigation resulting from the irregularities in the flow, or in the physical conditions of the bed of the stream; but they are also occasionally formed for the purposes of supplying irrigation channels, and for utilising the dynamical power of the water, when the rivers with which they are connected are of, comparatively speaking, insignificant volume, and are but little exposed to floods. The works executed upon the banks of the Lea, or of the Test and Itchin, in Hampshire, may be cited as partial illustrations of the combined use of rivers for navigation and industrial purposes; and perhaps it is allowable here to express the regret that the recent introduction of the railway system should have so entirely diverted public attention from the subject. For although the canals thus alluded to are far from being such as to ensure the greatest results from the water privileges concerned, the practical economical benefits to the public produced by them have, nevertheless, been of a very extraordinary description, even without any reference to the effect produced by the economical transport of bulky articles. It is, however, upon the long rivers of continents that lateral canals produce the most remarkable results; because in nearly all such cases, there is a large agglomerated population upon the banks of the river, and there is a rude species of navigation on the main stream, exposed to the inconveniences which unfortunately attend almost every large body of fresh water until it becomes distinctly under the influence of the tidal action. Such rivers are, indeed, exposed to great differences of level from the effects of floods, or of droughts; they are often divided into narrow and tortuous channels; at times they flow with great rapidity over shallows, and at others they present long reaches of stagnant water of great depth; and, in fact, they present, in their natural state, almost insuperable difficulties to the establishment of a regular system of navigation, even when the average velocity of the stream is not so great as to render such an operation physically impossible, in both the upward, and the downward direction. Lateral canals must, therefore, be considered to be essentially the means of correcting the natural defects of a river, or water course, for the purposes of navigation.

One of the most complete works of this description hitherto executed is, perhaps, the lateral canal of the Loire, which is made throughout its length to present a clear water way of 5 ft. 3 in. deep, by a width of about 33 ft. on the water-line of the canal, and of 17 ft. in the clear of the lock chambers, the latter being made about 101 ft. long, measuring from point to point of cills. The projected works for the improvement of the navigation of the Seine, are perhaps rather of the nature of a river improvement than of an ordinary lateral canal; but they may be cited as illustrating the dimensions it is considered in Europe advisable to adopt as the maximum in either of such cases. The locks are made as nearly as possible 400 ft. long by 40 ft. wide, with a fall of 6 ft. 7 in., and the normal width and depth of the channel are made about 75 ft. by 6 ft. 7 in.; for the barges used upon the Seine are often as much as 140 ft. long, by 23 ft. 6 in. wide, with a depth of 13 ft. 4 in. from deck to keel, and are able to carry as much as from 400 to 500 tons of merchandise. Upon many other rivers of the continent, of our own country, and of North America, similar works have been undertaken; and, indeed, the lateral canals of the Canadian rivers may be cited as being amongst the most remarkable operations of the kind yet attempted. The Long Sault canal, by means of which the dangerous rapids of the Ottawa are turned, has a width of about 140 ft. on the water-line, with a depth of 10 ft.; and its locks are not less than 200 ft. long by 55 ft. wide, with a depth of water over the cill of 9 ft. The Welland canal, which is in fact a lateral canal to the St. Lawrence between the lakes Erie and Ontario, has locks 130 ft. long by 22 ft. wide, and 8 ft. depth of water; so that the schooners which navigate the inland seas of North America are actually able to pass from them, through the lower St. Lawrence, to the Ocean.

The details of lateral canals do not differ in any essential respect from

those of summit level canals, except inasmuch as the difference may be rendered necessary in consequence of their greater dimensions. It is, for instance, customary to form, both on ship canals, and large lateral

canals, what are called surf beams on either side of the main channel, for the purpose of destroying the effect of the waves caused either by the wind, or by the passage of vessels through the canal; but in ordinary canals this precaution is hardly necessary. Again, in lateral canals it is advisable to form towing paths on both sides, as in the case of ship canals; whilst a single towing-path will suffice for an ordinary artificial navigation. But the most peculiar works required for the formation of lateral canals are those connected with the passage from one bank of the river to the other, and those executed for the purpose of securing the uninterrupted discharge of the drainage of the cross valleys, or of the affluents to the main stream. In many cases these affluents are of sufficient importance to render it necessary to construct large aqueduct bridges; and at all times they require to be treated with care and attention in order to avoid floods.

In the annexed cut is represented one of the passages of the lateral canal of the Loire from one bank to the other of the river, rendered

necessary, be it observed, by the occurrence at a point lower down of a large affluent on the side thus abandoned; and as this work illustrates the various conditions attending similar operations in a very striking and comprehensive manner, it may be desirable to dwell a little upon its consideration. The Loire is a stream of a very irregular character, varying frequently and rapidly in volume; but it may be generally described as a mere thread of water in summer, and as a deep, broad, and rapid river in winter. Its tendency to inundate its banks has been resisted by the construction, at a very remote period of history, of banks insubmersible during ordinary floods, finishing at a height of at least 21 ft. 3 in. above the mean summer level of the stream—though some of the inundations of this valley have attained the height of at least 25 ft. These banks limit the course of the water during floods; but during the period when the river flows with its normal volume, the water is confined in a definite channel, by banks finishing at lower levels, as shown, so that moderate floods are allowed to discharge themselves freely, whilst the deep water channel is maintained. Under these circumstances the canal crosses the river by means of a small basin on the left bank, in which barges may lie in case the main stream should be in a state to render it inadvisable to attempt the passage; and from this basin there is a communication with the river by means of a sluice pointing in both cases down the stream, and whose axis forms an angle of 35 degrees with the bank. As the lock-chambers of this sluice are required frequently to keep out the river floods, they are provided with double sets of gates; one pointing up, and the other down, the stream of the canal itself; and the walls of the lock-chambers are finished off at the maximum height of the river banks. On the right bank, the canal recommences with a lock entrance of a precisely similar character to the one upon the left bank, terminating in a rather wide bay of the canal; which bay, in its turn, ends in a circular basin, wherein the barges are able to change their direction. It will be necessary hereafter to revert to the reasons for placing the entrances as shown.

Summit level canals, or those intended to connect the existing lines of navigation upon the streams which flow from the respective sides of an elevated ridge of land, are forcedly made to overcome great differences of level, and thus give rise to the necessity for the execution of peculiar and special works for that purpose; and, as they are also forcedly carried through the districts wherein the rivers are of feeble volume, they frequently render necessary the execution of important works for the supply of water. The questions connected with the height to be overcome, and with the water supply, are indeed amongst the most vital ones to a summit level canal; and the success of such an operation depends almost entirely upon the manner in which they may have been solved. The general principles which must be borne in mind in the formation of such a canal are, in fact, that their total length should be the least possible under local circumstances; and that the difference of level be as small, and the number of locks as few, as is consistent with the economy of the first cost; for the evaporation from the water surface, the loss by filtration through the banks, and by the passage of boats through the locks, are dependent upon those conditions. These remarks apply equally when the fall is both ways, or when it is only in one direction, or when the canal has one or two branches; for there are instances in which summit level canals have all their fall towards one river, as in the cases of the majority of the Belgian canals, without descending on the other side from the highest reach of the navigation.

The precise direction of a line of artificial navigation may be, and often is, diverted from that which would theoretically have been

desirable, in order to allow it to accommodate certain local sources of traffic; but after due allowance has been made for these disturbing causes, the physical characteristics of the district must be carefully attended to. Trial levels on the line of the axis, and cross sections of the country, must be taken; the various springs and water-courses must be gauged, and the actual uses to which they are applied must be ascertained; and the geological characteristics of the district, both upon the surface and at some considerable depth, must be ascertained; as well for the purpose of ascertaining the capabilities of the district to supply the materials of construction, as for the purpose of obviating any tendency on the part of the natural ground to facilitate the passage of water. Very elaborate investigations must be made into the conditions of supply of water to the summit level, and that supply must be proportioned exactly to the wants of the navigation; the latter will depend upon the length of canal to be supplied by the summit or regulating bay, and will be influenced by the length, breadth, and height of the locks, and by the number of boats passing. Under some circumstances, when, for instance, the supply of water is liable to be deficient, it may even be advisable to substitute inclined planes for locks: in other cases, it may be necessary to compensate for the irregularities in the character of the natural water-courses, by forming impounding reservoirs, to which the surplus rainfall of the watershed may be stored. It is desirable, in laying out a canal of this description especially, that the reaches of level channel should be as long as possible in order to admit of a concentration of lockage; for by that means an economy will be effected in the time of passing boats through the locks, and in the superintendence and repairs of those works.

In some very exceptional cases, the summit of the depression, or pass, between the heads of two valleys is occupied by a small mountain lake, which pours its waters respectively into the natural channels of either side, and thus forms at once a regulating level, or reach, in the navigation. The pond of Longpendu is an illustration of this peculiar geological condition, for it pours its waters into the Loire on one side through the Bourbince, and into the Saône on the other, through the Heune, and thus acts as a natural feeder to the summit level of the Canal du Centre. The pond of Cony presents the same character, for it communicates on one side with the Moselle, and on the other side with the Saône; but this natural advantage has not yet been turned to any practical account, and the only artificial navigation of this part of France is effected by means of the Canal du Rhône au Rhin. In South America there is also a river of some magnitude which divides, in one part of its course, into two branches, one of which flows into the great river, the Amazonas, and the other into the Orinoco; but the occurrence of such natural facilities is very rare, and, in the majority of cases, the summits of the passes between the heads of two valleys have to be passed by means of tunnels or of deep cuttings.

The dimensions to be given to a canal will depend upon, 1st, the nature of the navigations already existing, which it is desired to place in communication; and, 2ndly, the traffic likely to be afforded by the locality traversed. In England it happens, from the fact of the extraordinary distance to which the tidal action of our rivers extends, that it is possible to confine the artificial navigation to very small barges; but upon the Continent, in North America, and in our own East Indian dominions, it would appear that there is a growing tendency to employ large boats, especially upon lateral canals or improved rivers. Thus, upon the Rhône the barges formerly used were about 75 tons burden, but the boats latterly constructed are made to carry about 120 tons; whilst upon the Seine and the Rhine (in the lower parts of their courses), barges are often used of a burden of from 400 to 500 tons; and in the United States many of the mixed canal and river barges are at least of 120 tons burden. In the execution of the artificial inland navigation hitherto formed, very great irregularities in the dimensions adopted have also prevailed in consequence of the opinions entertained as to the best description of barges; but the inquiries of the French engineers seem to have led them to the conclusion that it was desirable to group canals into two classes (so far as their dimensions were concerned), under the names of canals à grande navigation and canals à petite navigation. The former they made about 32 feet 9 inches wide on the floor-line of the canal, and 47 feet 5 inches upon the surface or water-line, with a depth of about 5 feet 9 inches;

Canal du Centre.

the locks being made 106 feet 8 inches long, by about 17 feet wide, and the towing-paths 13 feet wide. The canals à petite navigation are made only 35 feet wide on the water-line, with a depth of 5 feet, and the locks are constructed of 100 feet long by 9 feet 1 inch wide.

Average English Canal.

In England the dimensions adopted have varied within a very wide range, or from 31 to 48 feet upon the water-line, with an average depth

of 5 feet; but in some of our mineral districts the width is even reduced to 16 feet, and the largest of these secondary canals rarely

Chesapeake to Delaware.

attains the width of 28 feet. A similar irregularity in the dimensions of canals exists in America, for the St. Lawrence canal has a width of

Small English Canal.

150 feet, and the Morris canal is only 32 feet wide, on the water-line. It would be desirable that greater uniformity prevailed in this respect, for the inequality of dimensions often renders it impossible to pass the

Crozat Canal.

barges of one canal to another; and perhaps the dimensions adopted by the French engineers may, after all, be those which it would be the most advisable to adopt in the formation of new canals.

When the dimensions and direction of the canal are settled, the next point to be considered, as before said, is the mode of supplying the water required to compensate for the various sources of loss. These sources are of two descriptions, one of which is independent of the traffic, and the other in direct connection with it. The former of these sources of loss is produced by the evaporation from the exposed surface of the canal, the filtration through the banks, the leakage at the locks and lock-gates, and the loss which invariably occurs when a canal is refilled after being laid dry for repairs. The second source of loss is the one resulting from the consumption of water required to pass the boats through the locks, and occasionally from the sudden affluence of boats to the lower reaches of the canal.

The evaporation from any water surface will depend, of course, upon a very complicated series of phenomena, resulting from the conditions of the physical geography of the district in which it is placed. The laws affecting this branch of the inquiry would involve a discussion of some length, and they are, therefore, reserved for the articles, EVAPORATION and HYGROMETRY. For the present it may suffice to say, that in the temperate latitudes of Northern Europe, the average daily loss by the evaporation from the exposed surfaces of canals and their feeders is reckoned at from $\frac{1}{16}$ to $\frac{1}{12}$ of an inch; but in summer it often happens that the loss may reach even to four inches in the twenty-four hours; and, as it is precisely at this season that the ordinary compensations are deficient, it is essential to provide rather against the *maximum*, than against the *average*, evaporation. As to the loss by filtration, its amount must depend upon the care with which the works are executed, and the nature of the bed of the canal itself; but even when these various conditions are of the most favourable description, the loss of water may range between one-half and twice the amount lost by evaporation from the surface. It is usually considered that an allowance of two inches per twenty-four hours is sufficient to compensate for any loss of this description; but it must be observed, that the first time the water is turned into a canal, even with a most perfectly water-tight bed, a great quantity will be absorbed by the exposed surfaces before they become saturated, and this loss will be repeated on every occasion of laying the canal dry, though of course in a slighter degree than on the first occasion. It is usual to calculate upon the absorption of water at the rate of four inches in twenty-four hours, until the bed shall have become thoroughly saturated. In practice there is also another serious cause of loss of water upon canals, arising from defects in the execution of the locks and lock-gates; for, even when these constructions are new, they may allow a small quantity of water to pass, and after several years' wear they are certain to afford passage to increasing quantities. It is not rare to find the leakage of an old pair of gates equal to about 10,000 cubic feet per day.

The consumption of water for the passage of boats must depend upon their numbers, upon the relative proximity of the locks, and upon the direction in which the navigation takes place. Probably it is sufficient to provide a supply of water to compensate for this loss, calculated at the rate of 18,000 cubic feet for each boat which passes through the lock of a large canal: this quantity is no doubt in excess of that which is absolutely required, but the carelessness of workmen is so great, that it is advisable to make a provision rather in excess, than short of, the real necessities of the case. It is customary, also, to allow about $\frac{1}{16}$ of the quantity absolutely required for the lockage, to compensate for the displacement of water which sometimes arises from the accumulation of boats in the lower reaches of a canal.

The dimensions to be given to the reservoirs, or to the regulating

bay when it serves the additional purpose of a reservoir, must be such as to ensure the fulfilment of all the above-mentioned requirements; but it is to be observed, that for many practical reasons connected with the regularity in the discharge of the water, and with the equalisation of the supply, it is preferable to make the reservoirs independent of the portion of the canal devoted to traffic. As, indeed, it may often be necessary to lay bare the whole bed of a canal, it must evidently be important to avoid the loss of water in the summit level, if that should happen to constitute a natural reservoir; and, at any rate, it must be more easy to control the passage of water from an artificial pond of this description, than it can be to divert the flow of the outlet of the natural drainage of a particular district. It would also be found, generally speaking, to be the case, that the water flowing into the summit level from the natural surface of the country would contain so much alluvial matter as to produce a tendency to silt up the channel, and that at times it might enter with sufficient violence to injure the banks. If, however, any springs, or rivers of a constant volume, should occur upon the line of the canal, they must of course be used as far as possible, and artificial reservoirs must only be considered as costly methods of supplying their absence, or of impounding the surface waters, which would otherwise be wasted. There are many very important practical questions connected with the execution of these works, which are at the present day of quite as much importance to the sanitary operations of some districts as they are even in canal operations; and it has therefore been considered advisable to treat them collectively under the head RESERVOIR.

Before entering upon the examination of the works of art upon a line of canal, it may be advisable to dwell upon some of the questions connected with the channel or bed. The first remark to be made is, that in the execution of a canal it is desirable to set out its course, as far as possible, upon that bank of the watercourse, whose direction it follows, which has the smallest number of affluents. Any natural streams which may exist must be either diverted into the canal, if their waters should happen to be of a proper quality, or they must be carried under its bed by means of culverts or of aqueducts. Again, it is advisable to make any change of direction in the line of the canal with as large a radius as possible; and even to provide, in such positions, an increase of width in the canal which should allow the boats to pass one another with greater ease, a precaution which, by the way, it is advisable to repeat whenever, from any accidental circumstance, there may be danger of the existence of any interference with the free movement of the boats, as, for instance, in long deep cuttings, or at the outlet of a tunnel, or at the end of a series of locks. In the execution of small canals such 'turn-outs' are of absolute necessity, and they must be placed so that the bargemen can easily see from one to the other. In large or in small canals alike, however, when intermediate stations or wharves are established for the convenience of local traffic, they must be formed beyond the line of the main waterway, so as to allow the navigation to be carried on uninterruptedly. If, therefore, there should be only one towing-path to the canal, the wharves should be placed on the opposite side to that path, and beyond the line of the main bed of the navigation.

Formerly the impermeability of the bed of a canal depended entirely upon the perfection with which the puddling had been performed; and though at the present day the use of hydraulic lime concrete in forming the bed has been largely applied by the French engineers instead of the ancient system, the use of puddle is still so common that it is necessary to allude to it. Puddle consists of clay, or loam, which is reduced to a tenacious but plastic state, by working and chopping it about with a spade, with the addition of a certain quantity of water, until the whole mass becomes homogeneous and so much condensed that it will not allow the passage of water through its texture. The best description of earth for forming puddle is a light loam, with a mixture of coarse sand or fine gravel; very strong clay is unfit for the purpose, on account of the great quantity of water it naturally holds, and of its tendency to shrink and crack in proportion to the evaporation of that water; and vegetable soil is even more unfit still, for the roots and leaves of plants it contains not only serve to render it porous by their decay, but they likewise offer temptation to moles, rats, and other burrowing animals. The ravages of these creatures are sometimes so serious in their effects upon the water-tightness of a canal bed, that it is considered to be necessary, when the puddle stuff does not contain gravel or sand, to mix those articles artificially in order to resist their attacks; care must, however, be taken that the size of the stones in the gravel should not exceed that of musket-balls. Telford used to consider that the operation of working the puddle consolidated it to such an extent as to reduce its volume to about two-thirds of its original bulk; and both in his specifications and in his publications upon the subject of canals he prescribes numerous precautions for its preparation and use. Of late years, however, the thick bed of puddle, which is always of difficult execution, and moreover always exposed to accidents, has been replaced by a layer of concrete; in the case of the Canal de St. Quentin, a lining of that material of only eight inches in thickness was found successful in resisting the passage of water through the banks, which it had not been possible to close by any of the ordinary methods. Whether puddle or concrete be used, it is, however, essential to protect the impermeable hearting of the bed by covering it with a layer of earth, which should be of sufficient thick-

ness to prevent the gaffs used by the bargemen from entering or breaking its surface. This protecting coat is usually made about one foot thick, and when concrete is used for the lining it is advisable to form a step at the angles of the banks to prevent the protecting coat from slipping.

It is also to be observed, that in setting out a canal a longitudinal fall must be given in order to ensure the flow of the water with sufficient rapidity to compensate for the various sources of loss above enumerated, but at the same time that velocity must never exceed from twelve to fourteen inches per second. On some parts of the Erie Canal a fall of one inch per mile was given, whilst in others the rate of inclination was made only half an inch in that length, the consequence of which was, that when the navigation was active great attention was required to maintain the water at its proper level. M. Girard, the engineer of the Canal de l'Oure, reasoning from the longitudinal profiles of rivers, thought that it was advisable to make the fall of that canal a portion of a large catenarian curve; and he therefore, in one part, made the inclination 0.0000625 m. per metre, and in the other 0.0001236 m. per metre. The effect of this change of inclination, however, was simply to produce a rapid current over those parts of the canal where the fall was great, and a very sluggish current in the more level portions; so that it would appear to be important, especially when the water in the canal is intended to have a definite rate of flow, to maintain a perfect uniformity in the inclination of its longitudinal section.

With respect to the width and depth to be given to the channel or bed, the ordinary dimensions of which have been previously described, it may be advisable to state that the principles which should regulate that width and depth are generally admitted to be that the bottom or floor line should be twice the width of the widest barge likely to enter the canal, with an allowance of from six to eight inches play on each side. The banks of the canal must, if formed in earthwork, have inclinations of one and a half to one; and indeed it would be preferable to make them two to one, unless the slopes are protected with masonry or with rough pitching; it is advisable also to form a small surf-beam even in small canals, in order to prevent the barges from injuring the banks. The depth of water should always be made at least from twelve to eighteen inches greater than the draught of the largest barges navigating the canal, in order to obviate any inconvenience from the accumulation of silt, or from the growth of aquatic plants, or from the occasional differences of level produced by the passage of the boats through the locks or basins. In some cases the growth of aquatic plants is encouraged as a protection to the banks; but unless they are kept within strictly defined limits they are susceptible of producing much injury to the navigation. The effect of the unexplained introduction of the *Anacharis alsinastrium* upon our canals has indeed been so serious as to merit more than a passing notice.

The towing-paths must be made at least from twelve to sixteen feet in width when that operation is effected by horses, and they should be made and maintained with almost as much care as would be observed in the case of an ordinary turnpike road. When the haulage is effected by men, the width of the paths need not exceed four feet; and upon some of the most frequented canals on the continent a small berme is raised on the edge of the path, to protect it from the friction of the tow-rope. When the quick boats upon the Scotch principle are used, or when steam-vessels of any description ply upon canals, especial precaution must be taken to prevent the banks from being washed away by the waves thus produced. On the Scotch, and on some of the French canals, the banks have been paved for this purpose; and on the great North Holland Canal a rude species of camp-sheeting has been executed with the same intention.

The philosophical considerations connected with the flow of water in canals, and with the resistance of water to the displacement of floating bodies, enter so intimately into the science of HYDRODYNAMICS, that they are reserved for that head.

In the construction of a canal, the most important works of art, using that expression to designate the works which require the employment of skilled labour, are, 1. the communications with the natural watercourses or rivers; 2. locks; 3. aqueducts, siphons, and culverts; 4. over-bridges; 5. tunnels; 6. basins, docks, or entrepôts, and intermediate stations. As was before observed, the construction of reservoirs will form the subject of a separate article.

1. *The communication with Rivers.*—In the cases of lateral and ship canals it is necessary to consider the conditions likely to affect both

Entrance from river.

the upper and the lower junctions with the existing means of navigation; but in summit level canals the two ends are placed upon the

natural watercourses so as to render both of them in fact lower junctions. A careful examination of the best works hitherto executed shows that it is preferable to place the upper junction at rather an acute angle with the natural flow of the river, and to place the opening towards the down stream; for unless the boats are hauled back in this manner, they are exposed to be carried by the stream with dangerous violence against the entrance walls. If it were possible so to do, it would be desirable to form a basin near the guard-locks; but when this cannot be done, the junction should be formed by a long curve of considerable radius, and it should be made rather wider than the straight part of the canal. In order to prevent any inconvenience from the differences of level in the river, it is necessary to construct a lock with a pair of gates at each end; and it is also advisable to make a provision in the walls of the entrance channel for placing a dam, in case it should be required at any time to close the canal. The principal difficulty which occurs, however, in the construction of the upper junction of lateral canals, arises from the fact that they are usually established upon rivers of a very variable regimen, and that, under such circumstances, it is often necessary to form a cross dam to uphold the river waters. Very great precautions are required, in these cases, to prevent any injurious action from the water falling over the dam; and also to prevent the silting up of the pond of still water thus formed, or of the entrance and basin which are connected with it. In some cases the gates at the entrances are made in separate portions, to allow of their being easily used under considerable differences of level in the river; and in others, again, the first basin of a lateral canal is so arranged that its level may be alternately either above or below that of the river. Double sets of gates are required when this system is adopted, which must be made to point, as necessary, to the up or the down stream.

The outfall, or bottom junction with the river, may be either situated directly upon the stream itself or upon some branch com-

municating with it; and this latter course is adopted when there is danger of the outfall becoming silted up, or of the formation of natural bars, in consequence of the movement of the alluvial matters of the river. However this may be, the principles to be observed in forming such outfalls are—firstly, that the passage of boats from the canal to the river, or *vice versa*, should be easy; secondly, that there should at all times exist a sufficient depth of water; thirdly, that it should be possible, if required at any time, to place sluices for the purpose of scouring the channel; and fourthly, that there should be a basin of considerable area, to receive the vessels about to pass from the one description of navigation to the other. The quays of the lock chambers, basins, and the platforms at the entrances must be kept above the level of the highest tides, or of the land floods; and it is advisable to keep the basin above mentioned open to the canal, so that all the lockage which may be required may be effected in the entrance channel. In establishing the lower cills of the locks of ship or lateral canals which terminate in tidal rivers, it is customary to make the level of those cills correspond with that of the mean low water of neap tides.

2. *Locks and Lock-chambers.*—Locks are, in fact, a species of pounds, in which a portion of the water of a canal is retained within a structure of such a nature as to allow its surface to correspond with the surfaces of either of the reaches of the canal, situated at different levels, which it may be desired to place in communication with one another. This is usually effected by constructing in masonry a small entrance channel, an upper pair of lock-gates, a lock-chamber, a lower pair of gates, and a small exit channel similar to the one on the higher level; and in the gates, or in the side walls of the chambers, small sluices or paddles are formed, through which the water may be passed from one level to the other, so as to fill the chamber to the upper level when the lower pair of gates is closed, or to lower it when the upper gates are brought into use. The operation of passing a boat from one level to the other is called 'locking up' or 'locking down,' as the case may be.

Ellesmere Canal.

The number of locks required to compensate any given difference of level must of course depend upon the fall given to them, and as a general rule, it may be asserted that all the falls of a canal should be made equal, in order to economise water in the passage of the boats. It is to be observed that great falls entail the necessity for more perfect execution of the work, because under such circumstances the hydrostatic pressure upon the lowest part of the floor is increased in proportion to the depth of the water; but evidently the greater the fall the fewer need be the locks to overcome a given difference of level, and therefore there will be an economy of time and of

locks as possible within a short distance; but of course it is necessary in such cases to observe particular precaution in the mode of construction adopted, on account of the increased pressure upon the lower

lock floor, and of the danger of filtration. A number of consecutive locks, it is also to be observed, consume more water than the same number of locks separated by long reaches of canal would do. The falls given to locks vary, according to circumstances, between 5 feet and 10 feet, in canals with 6 feet of water; in ordinary canals, the fall is usually made from 8 feet to 8 feet 6 inches; and it is usually calculated that a boat would require as long a period to pass one such lock as it would do to traverse the distance of one-third of a mile on a level canal.

The parts of a lock may be considered to consist of—first, the upper chamber or head, with its gates, groove for dam, clapping cill, and breast wall; second, the lock-chamber, properly speaking, which extends from the upper breast-wall to the extreme point of the projection of the lower gates; and third, the breast-wall of the said lower gates and the lower chamber.

On many canals the form (on plan) given to the lock-chamber is made such as to give the side walls a concave direction to the water, with a view thereby to increase the resistance to the pressure of the

Lock. St. Lawrence Canal.

superintendence when there are the smaller number of these machines. For the same economical reasons it is desirable to concentrate as many

earth; and this pressure, it is necessary to observe, is greater than that of ordinary earth on account of the filtration which always takes place through the masonry of the locks, or from the upper reach of the canal. It is, however, more than questionable whether there be any real advantage in the adoption of this particular form; because the waste of water it entails is a permanent source of expense, and moreover it is tolerably certain that the extra thickness it will be necessary to give to the lock-floor will more than counterbalance the economy produced in the side walls. For these reasons, therefore, in the best modern canals the lock-chambers are made with parallel sides; and unless the chambers should be formed in the earthwork itself they are also made with vertical sides. The materials usually employed are masonry, whether of stone or of brick; but in Holland, the United States, our own colonies, &c., it may occasionally be advantageous to substitute timber, and even in some instances in our own country, cast-iron has been advantageously employed instead of masonry. Of whatever materials, however, the locks may be formed, the top of the side walls should be kept at least two feet above the maximum water-line of the upper basin.

It is usual to form grooves in the upper and lower chambers, to receive the ends of the temporary dams which may occasionally be required for the purpose of repairing the locks. These grooves should be made about 8 inches square, and of the whole height of the side walls; they must be placed at such a distance from the return walls as to allow a sufficient resistance to the various actions upon the foot of the dam. A reveal must also be formed on each side to receive the gates when open, and it should be made about 4 inches deeper than the gates, and 6 inches longer than their development. In order effectually to protect the gates when shut back in these reveals, the side walls must be carried from 6 feet to 7 feet beyond them on the upper side, before arriving at the groove last mentioned; on the lower side, the walls are prolonged beyond the reveals according to the width of the opening. Thus, for a 15 feet lock, they should be prolonged 12 feet; for an 18 feet lock, 14 feet; for a 20 feet lock, 16 feet; and so on.

In calculating the thickness to be given to the side walls of a lock it is advisable to consider that the earth at the back thereof is a semi-fluid denser than water, and to make the walls of a thickness adequate to resist its action. Some continental engineers make the thickness equal to 0.50 of the height; but in our own country this dimension ranges from 0.25 to 0.50, and the usual proportion adopted is 0.40, for the lock-chambers at least; because it is customary to strengthen the walls below the tail-gates, and when a lock is joined to a dam (as is very often the case in river navigation works), the end wall to the upstream is also strengthened, in order to enable it to resist the weight of water and the filtrations which take place. The floor of a lock is usually executed with an invert, to enable it to resist more effectually the hydrostatic pressure of these filtrations; and it is usual to calculate its dimensions on the supposition that it must be able to resist a head of water equal to the total depth of the lock. The thickness usually given to the floor of a 16 feet wide lock is, therefore, 2 feet 8 inches; and that of a 20 feet wide lock is 3 feet 4 inches. But whatever thickness be given, precautions should be taken to intercept filtrations from the higher level, either by driving a row of close piling or by stepping the foundations below the level of the ordinary parts of the chambers, so as to break the thread of any stream which might find its way under them.

The clapping cills are laid with a projection towards the upper level of the water equal to between one-ninth and one-third of the width of the opening; in the most modern canals the proportion is made between one-fifth and one-sixth, but Professor Barlow states that a projection whose sides would form an angle of about nineteen to twenty-four, or between one-eighth and one-ninth, is the most advantageous. It is customary to allow the cills to project about one foot above the floor of the lock, to form as it were a species of shoulder against which the lock-gates should be able to bear; and when the floor is executed in stone or brickwork, wooden or iron cills are introduced to receive the immediate shock of the gates. It is often desirable to execute the masonry at the back of the cills as a portion of an arch abutting against the side walls of the chambers.

When the upper chambers terminate with a breast-wall, that part of the structure is made concave (on plan) to the lock chamber, in order to economise masonry, and to receive the prows of the boats lying between the gates. Formerly these breast-walls were built vertical, and their upper surface was made to range exactly with those of the

clapping-cills and the upper part of the chamber; but of late years the upper portion of the breast-wall has been made with an incline towards

the chamber, and the face has been formed with a concave front towards the same direction, in order to break the fall of the water from the sluices in the gates; whilst in some of the most modern works, the breast-walls have been suppressed altogether. It is more than questionable whether there is any advantage in this latter system; and certainly it entails considerable trouble and difficulty in the original construction, and in the subsequent management of the lock-gates and chambers. Owing to the agitation produced by the escape of the water from the lower gates, it is advisable to prolong the floor of the lower chamber for some distance into the bed of the canal; and in many cases the entry to the upper chamber is also paved, in order to prevent the excavations which might otherwise be occasioned by the velocity given to the water at the upper gate.

Especial precautions must be observed in working the grooves intended to receive the heel-posts, as it is upon the correctness with which they fit that the water-tightness of the lock mainly depends. In some cases these grooves are executed in stone, in others of hard wood, and in others of cast-iron; but whatever be the material employed, the greatest attention must be paid to their execution. Care must also be taken that no parts of a lock project, and in fact that there shall be nothing in the respective chambers likely to catch the boats, or their loads, during their passage through the locks. Mooring-posts and rings must be provided occasionally, and every provision must be made to facilitate the passage.

In almost all the important canals the lock-gates consist of two leaves, fitting close, and bearing against the cills at the bottom, and against the grooves at the sides. Generally speaking they are made of wood, but of late years many gates have been executed in cast, or even in wrought-iron, or in a compound system of cast and wrought-iron and wood. These gates are composed of the upright posts, distinguished

Upper Gate.

Lower Gate.

by the names of the *heel-posts*, and the *mitre* or *meeting-posts*; and of the *horizontal rails*, which support the weight of the water, and vary in number according to the height of the gate. Against these rails the planking, or the wrought-iron plates, as the case may be, are applied. The posts are kept about two inches clear of the floor of the chambers in which they work, so as not to bear immediately upon it in their revolutions; they are made from eight to ten inches above the highest water line, when they are opened by machinery, but are somewhat longer when that operation is performed by means of a long lever on the top of the gates, as is usually the case. The lowest rail, generally speaking, terminates at four inches from the floor, and the upper rail finishes about four inches above the water line; the intermediate rails are spaced according to the effort they are intended to resist. A raking brace, or strut, is introduced between the rails, and a wrought-iron tie connects the foot of the mitre-post to the top of the heel-post; these, together with the squares let in at the junction of the rails with the upright posts, serve to maintain the rigidity of the framing; but even with these precautions it is advisable, in preparing the gates, to keep the extremity of the framing at least two inches above the level it will occupy in execution, in order to allow for its shrinkage. In the most modern locks, the heel-posts turn upon a metal pivot let into the cill, and working in a reversed socket let into the post itself; and at the top they usually work in a metal collar, attached to the walls of the chamber.

The water is passed from one level in the lock to the other, by means of sluices formed on the gates themselves, or by means of small culverts in the side walls, or by siphons. The usual proportion of the water-way of the sluices to the width of the chamber is about 0.002 or 0.0013 to 1; the conditions which, however, regulate their dimensions are, that they should be made as large as possible, in order to allow the locks to be filled in the shortest space of time, without giving rise to a dangerous current or fall in the lower basin. The orifices should be placed, when vanes on the gates are used, as nearly as may be on the centre line of the leaves of the gates, in order that their jets may meet, and mutually destroy their effects. When side-culverts are used, the sluices are always placed on the upper side of the lock. It has, however, been found that there are so many practical objections to these side tunnels, that at the present day engineers have reverted to the old system of vanes on the gates. The dimensions of the vanes are ascertained by the formula $Q = m S \sqrt{2gH}$; in which Q = the quantity discharged; m = a coefficient expressing the relation between the real and the theoretical discharge, which is equal to 0.625 when

only one vane is used, and 0.548 when two vanes are used; S = the sectional area of the opening of the vanes; and H = the head above the opening.

When the navigation upon a canal is active, it may become advisable to place two locks side by side, so that one should be able to lock up, and the other down, simultaneously. In this manner it is easy to effect a considerable saving of water, by means of a culvert between the two chambers; and in some other cases, as in the Canal d'Antoing, the same object of economising water is effected by means of side chambers. On this Canal d'Antoing, a system was also adopted for

Side-pond on the Canal d'Antoing.

pumping the water, which had served to pass boats through a chain of five locks, back again into the upper reach of the canal; and in countries where water is scarce, this system may be recommended for imitation. There are, it may be added, an almost infinite number of inventions for the purpose of saving time in the passage of boats through locks, and for saving water during that operation, a description of which would extend this article to inconvenient limits. The reader is therefore referred for further details to Telford's *Life*, to Sganzi's *Cours de Construction*, Minard's *Navigation des Canaux et des Rivières*.

The proportion of locks per mile of canal is necessarily very variable; for it depends upon the longitudinal section of the country to be traversed. In England, the average upon the more important canals ranges from 1 lock in 0.33 mile to 1 in 1.43; in France, the average varies from 1 in 0.66 to 1 in 1.89; and in America, there is upon the Erie Canal on the average 1 lock in every 4.36 miles. Occasionally, in very hilly countries, locks are dispensed with altogether, and the boats are raised by means of machinery upon inclined planes, from one level to the other. Thus, in the Duke of Bridgewater's subterranean canals, there is one inclined plane 151 yards long, by means of which a difference of level of 35½ yards is at once overcome. On the Shropshire Canal there are three inclined planes, respectively of 126, 120, and 207 feet rise, executed about the year 1792; and Telford executed an inclined plane of the same description on the Shrewsbury Canal, of 223 yards in length and 25 yards rise. On the Canal du Centre similar inclined planes are used, on account of the want of water; and on the Morris Canal, Pennsylvania, there are no less than fourteen such planes, each of which has a rise of about 100 or 102 feet. In the latter case, the barges are run into a species of lock, which is carried upon rollers, so that the barges are kept constantly afloat. It is said that the economical results of these inclined planes are very satisfactory; but evidently they can only be applicable upon canals of small section, for even in the case of the Morris Canal, the weight of the boat, lock, and carriage is about 85 tons, and in a canal of larger dimensions the weight would increase in so marked a proportion as to increase the cost of lifting the load to a very serious extent. The vertical lift used upon the Bridgewater Canal seems to be the best for large canals.

3. *Aqueducts, Siphons, and Culverts.*—In traversing a great length of country, especially in a hilly or mountainous region, it may often happen that the canal would meet in its course streams holding much foreign matters in suspension, or subject to floods or droughts, of a capricious and dangerous character; and these streams may occur at different levels with respect to the water-line of the canal, requiring consequently a different treatment in each case. If the natural level of the stream should be above that of the canal, of course, it must be carried over it at once by an aqueduct; but this is a case which rarely occurs, and it is far more common to find that it is necessary to pass the water under the canal by means of a culvert, or of a siphon aqueduct. The construction of the culverts is simple enough, for all that is required of them is, that their water-way should be sufficiently large to carry off any flood which may occur in the upper parts of the valley they serve to discharge, and that they should be executed of impermeable materials, both for the purposes of resisting leakage from the canal above them and from their own bed. Greater difficulties, however, attend the execution of the siphons, for they are at all times difficult to repair; there is moreover great danger of their leaking, in

consequence of the hydrostatical pressure acting upon their lower surfaces; and there is a tendency to choke up the passage, from the accumulation of silt or alluvial matter. So great, indeed, is the danger from the latter cause, that siphons should only be used for the most limpid waters, and under any circumstances settling reservoirs should be formed at their entrances.

If the lateral stream thus encountered should attain considerable dimensions, it will become necessary to carry the canal over it by means of a bridge aqueduct, whose form, mode of construction, and dimensions must depend upon the particular circumstances of the case. It is very rarely that the width of the channel is made more than 8 inches on each side beyond the extreme width of the barges using the canal. Only one towing-path is absolutely necessary, though it is usual to execute two, and these paths are made 3 feet wide when the haulage is effected by men, or 6 feet wide when it is effected by horses. When, as it is usually the case, the aqueduct is executed in masonry, the actual bed of the canal ought not to be commenced until the centres have been struck, and the settlements of the materials have taken their full effect upon the piers and arches of the substructure. In the best modern works of this description, the bed itself is formed of hydraulic concrete; and under those circumstances, a strong timber guard is required to protect the concrete from the jars or shocks of the barges; as also an earthwork lining if the bargemen are likely to use their gaffs. The primary object to be borne in mind in executing an aqueduct being, in fact, that it must be water-tight, it is impossible to attach too much importance to the mechanical execution of the bed, and in some cases the engineers have even gone so far as to line the trough with lead. This was a needlessly expensive method of securing the desired end; but it is impossible to exaggerate the necessity for observing the minutest precautions to insure the impermeability of the channel, or the immediate removal of any water which may force its way through, without its being allowed in any way to compromise the solidity of the structure. For this purpose it is advisable to form small aqueducts in the haunches of the arches; and the warm air-flues, which are occasionally formed in these structures, may likewise be made to contribute to the same end. The water should be introduced as soon after the execution of the bed as possible, in order to prevent any fissures from the sudden drying of the lining.

Great difficulties are at times encountered in executing the foundations of canal aqueducts, from the fact of their being necessarily constructed in the beds of rivers, which are composed of loose alluvial matters of a great depth. This was the case with the aqueducts of Digoin and the Allier, erected over some of the torrential affluents of the Loire; and still more markedly with the great Solani and Godavery aqueducts recently executed in India. In the former cases, the foundations were protected by establishing a floor, over the whole of the water-way, between an upper and lower face-wall, and a close row of sheet piling was driven in front of each of the latter. In the cases of the Indian aqueducts, the native system of founding upon wells was adopted; for brick wells were sunk to a considerable depth, and subsequently filled in with concrete, forming, as it were, masonry piles, on which the superstructure was erected. Local considerations must determine the choice of the system to be adopted in any particular case, the object to be effected being to effectually guard against any tendency in the waters of the stream traversed to undermine the foundations.

Amongst the most remarkable canal aqueducts hitherto executed, it may be worth while to mention those upon the line of the Ellesmere and Chester Canal, by Telford, on account of the novel application in them of cast iron to building purposes. In the Chirk Aqueduct, the bed only of the canal was formed of that material; but in the Pont y Cyssite Aqueduct, the whole of the upper structure was executed in cast iron. The Lune Aqueduct, by Mr. Rennie, is a very bold and

Lune Aqueduct.

elegant structure; and there are some very remarkable works of this description near Leeds, executed by Mr. Leather, in which cast iron has again been employed on a very large scale. In France there are some remarkable aqueducts of masonry, such as the ones before mentioned at Digoin and Guétin, the former of which is 810 feet long, and the latter is 1298 feet long; and in the United States there is a great work of this description, of wood, 1077 feet long. The aqueduct of the Ganges Irrigation Canal is however the largest construction of this nature yet erected, for its actual water-way is not less than 170 feet in width by 10 feet in depth; the Godavery Aqueduct is of a smaller section, but its total length is not less than 2248 feet.

4. *Over-Bridges.*—The bridges to be erected over a canal being designed to accommodate the local traffic, it must be evident that the most important general condition to be observed in their construction is, that they should be kept as low as possible, consistently with the service of the navigation. It has been found, practically, that upon

canals having locks of 17 feet clear width, a height of 13 feet from the water-line to the under side of the keystone is sufficient; but that if the barges frequenting the canal are so large as to require the locks to be 26 feet in width, the clear height as above must be made 18 feet. Under these bridges, however, the water-way is usually made about from 1 foot 4 inches to 2 feet wider than it is made in the locks, because the boats do not stop to pass under them as they do to pass through the locks; for this reason also it is desirable, wherever it is possible so to do, to carry the towing-paths under the bridges, in order to avoid the necessity for casting off the tow-ropes. Over-bridges should always be placed in positions where the canal has a straight run above and below them of from 200 to 300 yards.

In very flat districts, as in the fen-lands of the east of England, in Holland, or in Belgium, it is often necessary to execute lifting, or swing bridges, in order to avoid the necessity for raising the level of the approaches. There are many ingenious modifications of this class of structures, such as the lifting bridges upon the Surrey canal, wherein the roadway is raised bodily by means of counterpoises; the ordinary Dutch lifting bridges worked by long levers fixed above the ground; the ordinary turning bridges, like those introduced upon the Regent's canal; or the rolling bridges recently applied upon some of the railway lines. But upon whatever principle these moveable bridges may be constructed, they are always costly in their first execution; and their subsequent maintenance, working, and repair always entails a considerable outlay. If possible, therefore, the erection of this description of works should be avoided, and permanent bridges with proper approaches substituted for them, especially in the neighbourhood of towns.

5. *Tunnels*.—When the cutting required for the purpose of carrying a canal at a given level becomes too expensive, from the mass of earth to be removed, and it is not considered advisable to diminish the depth of excavation by the introduction of locks; or when it is considered that there is a probability of meeting a copious supply of water by passing through the heart of a hill; tunnelling should be resorted to. Local considerations must at all times seriously affect the economical bearings of these questions, but, as a general rule, it is thought that when the excavation for a canal would exceed 50 ft. in depth, there would be an advantage in executing a tunnel rather than in executing such a cutting. Some engineers, in order to avoid the construction of tunnels, which certainly entail many inconveniences upon the navigation of a canal, reduce the width of the water-way in deep cuttings to that which is absolutely necessary for the passage of one boat; and, indeed, it is to be observed that the majority of canal tunnels also are made of this width. But the economy thus attained in a cutting is far less than might have been expected, because the cubical quantity of earth-work in it is mainly affected by the angle of the slopes, and the saving produced is, in fact, only equal to the amount resulting from the multiplication of the diminution of the width by the depth. There is also an objection to diminishing the width of a canal in such positions, arising from the obstruction thus offered to the passage of the boats from the smaller area of the water surface; and for the same reason it is not desirable to reduce the section of the channel even in tunnels.

Whether the tunnel be executed to allow the passage of one or two boats simultaneously, it is customary to give a play of about 2 ft. on either side beyond the width theoretically required. On the Canal de St. Quentin the tunnels are executed with towing paths on either side of 4 ft. in width: in the Paddington and the Harecastle tunnels, there

Harecastle Tunnel.

are towing-paths only on one side, and of smaller dimensions than is desirable; whilst in the Blisworth tunnel there is no towing-path, and the boats are propelled by a process technically called "legging," in which the bargemen lie on the top of the barge, and push it forward by pressing their feet against the top of the arch. In some cases the boats are hauled through the tunnels by means of tow-ropes fixed at the respective ends; and again there is, in other canals, special machinery for the purpose of haulage.

The height to be given to the underside of the lining of a tunnel above the water-line is usually made between 11 ft. and 16 ft.: in the case of the canal between the Chesapeake and Ohio, this height was made 17 ft. 3 in., and in that of the canal St. Quentin it was made 20 ft. In all these cases it is supposed that the masts of the barges are either struck or lowered; but in the project for the great inter-oceanic canal, by M. Garella, for uniting the Atlantic and Pacific, it was suggested that the clear height of the tunnel, near the summit level, should not be less than 122 ft. At all times, however, the clear

height to be given must depend greatly upon the transverse section of the tunnel, and this will in its turn be affected by the nature of the strata traversed. For instance, in the Thames and Medway tunnel the chalk was so fissured, and the strata were inclined at such an angle, that it became desirable to throw out the tunnel to the form of a Gothic arch, rising occasionally as much as 31 ft. 8 in. above the water-line: whilst in the more uniform strata met with in the Harecastle tunnel, the height could at all times be kept within the limits originally intended. Whatever the form of the sides and of the vault may be, the bottom should be formed by an invert. The thickness of the lining (and it may here be observed that it is very rarely indeed that the lining of a tunnel can be dispensed with) must depend upon the nature of the ground traversed, its hygroscopic powers, and the inclination of the strata. It appears, from an examination of the most successful examples of such works, that the extreme thickness to be given to the vaults need not exceed 3 ft. 4 in. or 3 ft. 6 in. even in the largest tunnels, and the worst descriptions of soil; the sides should be made about from 6 in. to 12 in. thicker. [TUNNELS.]

6. *Basins, Docks, and intermediate Stations*.—At the termini of an important line of navigation it is necessary to provide accommodation for the transaction of the business to which it gives rise, or to provide wharves where the barges may unload or receive their cargo, and where the goods they transport may be stored for sale, or transhipped at once into seagoing vessels if required. It must, therefore, be evident that the nature of the terminal arrangements must depend greatly upon the local conditions under which they are placed; and that the principles which would be applicable to a ship canal would be very different from those applicable to a mere summit level one. The only invariable rules which apply to this class of works are, that the area of the basins should be sufficient to allow the barges or vessels, which are being loaded or unloaded, to lie alongside the wharves without interfering with the movement upon the canal itself; and that the level of the water in the basins should be maintained independently of that in the inner reaches: in the best canals there are therefore locks at the junction of the canal with the basins, for the express purpose of isolating the level of the former if it should be requisite so to do. In the cases of canals terminating in a tidal river, the observance of this precaution is more than usually imperative.

The area of a terminal basin depending, as was above stated, on the character of the vessels resorting to it, it follows that the basin intended to serve the purposes of both the canal and the deep sea vessels must be much larger than the terminal basin which is exclusively devoted to the purposes of the inland navigation. For ordinary working operations, it would appear that it is not desirable to allow more than two tiers of vessels to lie alongside of the wharves of a dock at the same time; and it is also known that it is essential to leave a space between the vessels moored alongside the quays, which should allow at least one of the longest of the vessels using the dock to move freely in any direction. The minimum width of a basin must, then, be equal to at least four times the width, plus once the length, of the largest vessel it is intended to receive, and plus the space to be left between each of the elements of the calculation; and its length should on the average be equal to at least ten times that of the longest vessel using the basin, plus four times the width of the said vessels, in order to allow some boats to moor at the ends. The unloading machinery, cranes, staiths, derricks, and timber slips, must be regulated by the precise nature of the traffic of the canal, and they cannot give rise to any very general observations. The terminal basin of the Regent's Canal is one of the most perfect structures of this description in existence; the Basin de la Villette, in Paris, is a very fair specimen of an inland basin in a great town; whilst the details of the Entrepôt des Marais may be advantageously studied, on account of the ingenious combinations therein effected to facilitate the vexatious operations of the French Custom House.

Intermediate stations upon a canal must be established mainly upon the same conditions as have been above traced for terminal stations; observing, simply, that precautions must be taken to prevent the barges lying alongside the wharves from interfering in any manner with the through traffic. It would, indeed, be advisable to place any important intermediate stations upon lateral branches from the main line of the canal.

Statistics.—It would be difficult at the present day, when so many canals are being transformed into railways, to give any very accurate statistics of the lengths of canal actually in existence. From the observations of Mr. G. Rennie, it would however appear, that in the years 1838 and 1839, before this description of change had taken place to any notable extent, there had been formed in Great Britain about 2236 miles of improved river navigation, at a cost of 6,269,000*l.*; and a total length of 2477 miles of artificial canal navigation, at a cost of 28,406,389*l.* In the United States there had been executed up to the same period about 2000 miles of canal, at a cost of about 9,200,000*l.*; and in France there were about 1974 miles of canal, which had cost about 12,257,184*l.* The average annual cost of maintenance varies from 180*l.* to 600*l.* per mile of canal, according to the nature and activity of the traffic. As a general rule, it may be assumed that the cost of a canal may in England be estimated to be about 4*l.* per yard lineal, with an addition of 1000*l.* per yard vertical of lockage, or rather with an addition of about 3000*l.* for every lock of ordinary dimensions. The

cost of basins and intermediate stations is not included in these prices, on account of their very variable importance; but as a rude approximation, they may be assumed to cost about one-tenth of the total cost of the rest of the canal. Common, under, or over-bridges are not included in the above prices; but they may be considered to cost about 500*l.* each.

CANARIES, in music, a quick dance-tune, in three-eight time, said to have been imported from the Canary Islands, though in all probability it was exported thither from Normandy by John de Bethencourt, who invaded them at the close of the 14th century. Purcell has, in his 'Diocletian,' introduced the *Canaries*. His tune is in two strains of eight bars each, in three-eight time.

CANARY GRASS (*Phalaris Canariensis*) is an annual grass, cultivated for its seeds, with which cage birds are fed. The consumption of this seed is so considerable as to make it an article of commerce. Canary seed is chiefly cultivated in the Isle of Thanet in Kent, and about Sandwich. It requires a good soil, neither too light nor too wet, and an open country, without many hedge-rows; for small birds are so fond of the seed, that where they abound it is scarcely possible to protect the crop from their depredations. The plant grows like a strong grass, with an oval spike at the extremity of the stem. The seeds are closely enveloped by a strong chaff or husk, from which they are not easily separated; they are oval and pointed at both ends, and of a bright straw colour. The kernel of the seed is pleasant to the taste, and has the flavour of nuts.

Canary grass has been tried in a green state for cattle; but besides the price of the seed, which is high compared with that of other grasses, it has not been found sufficiently abundant or nutritious to make it preferable to any of the grasses usually cultivated for that purpose. When sown for the seed it is best sown in drills, about half a bushel to the acre, at the distance of eight or nine inches from each other; this admits of hoeing, by which the quantity of seed produced is much increased, and it is kept free from the admixture of weeds. When it is reaped it is left for some time in heaps or wads, and exposed to the dews: this does not injure the seed, and by softening the husk facilitates its separation by threshing. The same effect may be produced by breaking off the heads from the stem with the flail, and pressing them close in casks or bags before they are perfectly dry; a slight fermentation takes place which renders the chaff brittle, and after some time the seed comes out very readily. The same thing is done with clover seed. The produce of an acre of canary seed is from three to five quarters.

CANCER, a disease of a malignant character. This disease depends upon the exudation from the blood of a peculiar matter, accompanied by the development of fibres and cells. This exudation produces a tumour or swelling, which ultimately ulcerates, forming an open sore. Dr. Bennett divides these tumours into three kinds: 1. The structure is very hard, and principally formed of fibres (*schirrus*). 2. The structure is soft, containing a copious milky fluid, in which numerous corpuscles swim (*encephaloma*). 3. The structure has a fibrous basis, so arranged as to form areolæ or loculi, containing a gelatinous gum or glue-like matter (*colloid cancer*).

1. *Schirrus*.—On making a thin section of a schirrus tumour, it is found to be principally composed of filaments, which vary in size and run in different directions, sometimes forming waved bands, at others an inextricable plexus, among which nucleated cells may be seen to be mixed. These nucleated cells are peculiar to cancerous growths, and are called *cancer cells*. They are round, oval, caudate, spindle-shaped, heart-shaped, according to the pressure to which they have been subjected. They vary in size from the $\frac{1}{1200}$ th to $\frac{1}{400}$ th of an inch. When young, the cell-wall is smooth and distended; when old, they are more or less corrugated and flaccid. Each cell contains at least one nucleus, sometimes two or more. Such is the microscopic structure of schirrus.

Schirrus is an indolent, hard, and nearly insensible tumour, accompanied with little or no discoloration of the surrounding skin. It commonly commences as a small hard knot in the part which it attacks, and from this minute spot spreads in all directions, like rays from a centre. In this state it has little or no pain, and it may be either distinctly circumscribed and movable, or blended with the surrounding substance, and scarcely at all movable.

As the disease passes from an indolent into a more active state, the size of the tumour enlarges; its surface generally, though not invariably, becomes unequal; pain begins to be felt in it, slight at first, recurring at intervals, and progressively increasing, being always of a shooting or lancinating kind; the skin acquires a purple or livid hue; the cutaneous veins enlarge, become what is termed varicose, and spread out over the livid and puckered skin in such a manner as to present some likeness to the body of a crab with its claws extended, whence it has received the name of cancer. The most characteristic marks of a true schirrus then are puckering of the skin over the tumour, dull leaden colour of the integuments around it, knotted uneven feel of the tumour, and occasional darting pains through it. If to this assemblage of symptoms be added a uniform resistance to all the remedies employed to disperse the tumour, a constantly progressive enlargement of the tumour, and a manifest tendency to involve contiguous parts in the same morbid condition, the evidence of the true nature of the malady will be indubitable.

The rapidity of the progress of a schirrous tumour to open cancer is different in every different case. Sometimes indeed the induration remains in the state of schirrus for many years, and even to the termination of life, the skin never actually breaking. At other times the interval is short from the first discoloration of the skin to its termination in the state of ulceration, or the formation of open cancer.

The carcinomatous ulcer consists of a large chasm formed in the substance of the part in which the malady is seated, the chasm being produced partly by a sloughing and partly by an ulcerating process. The opened tumour is now found to consist of cells; as these cells burst and pour out their contents, which consist of a pulpy matter of different degrees of consistence and of various colours, the surrounding parts are irritated by an excoriating ichor. This discharge sometimes takes place with a celerity which would induce the belief that it can scarcely result from the process of secretion. When the diseased actions have in a manner exhausted themselves, an attempt at reparation appears to take place, analogous to those which in other cases lead to the restoration of a part from a diseased to a healthy state. New flesh is formed, but instead of healthy muscle it consists of a fungus of peculiar hardness, the formative vessels communicating to the new product the same qualities as to the tumour previously generated by their morbid action. This diseased fungus occasionally even cicatrises, and so arrests for a time the progress of the disease. But the morbid action, though mitigated or suspended, is not subdued; it soon recommences its destructive course, and the part never returns to a healthy condition. In the meantime the disease extends through the medium of the absorbing vessels, and by their agency is propagated to parts at a considerable distance from the original tumour.

In the progress of the ulceration a good deal of blood is often lost from the destruction of the coats of the blood vessels. A burning heat is felt universally over the ulcerated surface, the source of unceasing torment. The shooting lancinating pains, sufficiently distressing in the occult state of the disease, now increase both in degree and constancy, and the strongest constitutions ultimately sink under the progressively augmenting irritation and suffering.

When a section is made in a schirrous tumour, in the early stage of its formation, its central portion is found to be more compact and harder than the other parts of its substance. This central portion, which often does not exceed in magnitude the size of a silver penny, is nearly of the consistence of cartilage, and from this centre radiate in all directions, white, firm, ligamentous bands, which are crossed by transverse bands of a somewhat fainter appearance, and in this manner is formed a kind of net work, in the meshes of which the new-formed substance is enclosed.

In an advanced stage of the tumour the whole of the diseased part has a more uniform structure; no central point can be distinguished; and the ligamentous bands which extend in every direction, and which are still very apparent, do not follow any regular course, or at least not distinct enough to be traced.

When the tumour passes into the state of ulceration, the central part of the ulcer consists of a small irregular cavity, which is filled up with a bloody fluid, the edges of the cavity being hard, jagged, and spongy, and exquisitely painful. "Beyond the edges of the cavity there is a radiated appearance of ligamentous bands, diverging towards the circumference; but the tumour nearer the circumference is more compact, and is made up of distinct portions, each of which has a centre, surrounded by ligamentous bands in concentric circles."

Encephaloma also presents a fibrous structure, but it is very loose when compared with that of schirrus. In the harder parts it presents fibres, but in the softer parts no traces of fibres can be found. On cutting into one of these tumours it is found to be more or less mottled with a grayish, pinkish, reddish, yellow, or blackish colour, from varying degrees of vascularity. The reddish forms of these tumours are what is known by the name of *Fungus hæmatoides*. The yellowish forms are dependent on a fatty degeneration of the cancerous matter, whilst the black forms are owing to the growth of black pigment cells. This constitutes the *melanosis* or *melanic cancer* of some authors.

On placing some of the soft cream-like fluid under the microscope, it presents a large number of the cancer-cells, which are mixed with a number of rude cells and granules, compound granular cells, blood corpuscles, and more or less fibres. The cells are often degenerated, presenting crystals of margarine and cholesterine. Sometimes it is mixed with a good deal of calcareous matter.

3. *Colloid cancer* is composed of fibres arranged in such a manner as to form areolæ or loculi which are filled with a gray or amber-coloured glutinous matter, which is sometimes transparent, at others opalescent or semi-opaque. This matter is sometimes found quite structureless, or exhibits only a finely molecular surface. At other times it contains numerous cancer cells. It occurs on free surfaces, as the peritoneum, &c. When collected in masses it has an irregular nodulated aspect.

These three forms of disease occur at all periods of life, attack all organs of the body, and both sexes. They are less frequent in the young than in the aged. Females are more liable to them than males. Schirrus has a tendency to attack the glands of the body, and is especially frequent in the female breast. [BREAST, DISEASES OF.]

The causes which lead to the development of these terrible cells, which when once they have begun to form, go on to form others

till the tissue in which they are developed is destroyed, and the system is worn down by their unnatural growth, are hidden in obscurity. Sometimes a suspicion has been created of inoculation, at other times hereditary tendency seemed to account for it. With regard to the first, the evidence is deficient. With regard to the second, it is shown that only a limited number of cases occur in persons whose parents have had the disease previously. Mr. Paget, in his 'Lectures on Surgical Pathology,' says that in only a sixth of the cases of cancer can there be traced any hereditary transmission. As cancer is not an uncommon disease, a large proportion of these cases may have no relation of transmission, but have occurred independently in people related. The tendency to the transmission of this disease is, under any circumstances, not so great as is usually supposed.

With regard to treatment, this must always be palliative. The disease is necessarily a fatal one, and the presumption always is, in the case of a tumour getting well, that it was not cancer. This ought to put people on their guard against those who pretend to cure cancer. Harmless tumours are always easily cured [TUMOUR], and these are often called cancer, and thus credit is obtained by ignorant or designing men for the cure of this disease. A temporary benefit is sometimes derived from the removal of the tumour. Mr. Paget states that the average duration of life after the appearance of the cancer is 49 months. He then adds, "In 49 cases in which the cancer was once removed by operation, the average duration of life after the first observation of the disease was again something more than 49 months. I believe, therefore, that the removal of the local disease makes no material difference in the average duration of life." But, he adds, it appears "probable that the course of the more rapid cases is retarded by operation."

With regard to the treatment, it divides itself into *local* and *general*. The local treatment is directed either to *remove* the disease, or to relieve the pain. The evidence is not more satisfactory of a removal of the disease by escharotics, as caustic potass, chloride of zinc, tannic acid, &c., even when applied after producing incised wounds in the tumour, than in removing by the knife. The relief of pain seems a more rational indication, which may be obtained by the application of hemlock, henbane, opium, chloroform, and other local anaesthetics. The general treatment consists in keeping up the strength of the patient, and procuring freedom from pain, and sleep, by the soporific narcotics.

(Paget, *Lectures on Surgical Pathology*; Bennett, *Clinical Lectures on the Principles and Practice of Medicine*.)

Cancer in the Domesticated Quadrupeds is oftenest observed in the bitch, and every character and stage of it may be satisfactorily traced. A small, hard, insensible, isolated tumour is felt in one of the teats. It seems to give no pain, and causes no kind of inconvenience; it is not larger than a pea, perhaps not of greater size than a millet seed. During many months it seems scarcely or not at all to grow, but it never retrogrades. After an indefinite period of time however it begins evidently and rapidly to increase, and smaller ones may be detected at its base. It then assumes an irregular figure, and the whole, or portions of it, become hard—of a schirrous hardness, and perfectly incompressible; other portions are soft, perhaps hollow, and cellated. At length a portion of the tumour begins to become prominent and soft. It is intensely red, then purple, and after a while it breaks, and discharges a corroding ichorous fluid. The tumour is evidently disorganised deeply within its substance, and a cancerous ulcer, with an irregular elevated edge, is established. Perhaps it heals in the course of eight or ten days, but it soon opens afresh, wider and deeper, and at length the animal is destroyed, either by the general irritation which is established, or by the contamination of the circulating fluids, which are speedily affected by the vitiated secretion of the part.

Iodine, which has so much power in dispersing glandular and many other tumours, is inert, whether applied externally to the cancerous tumour or ulcer, or administered internally, in order to affect the constitution. The excision of the tumour is generally useless after it has acquired any considerable bulk, for it will appear on examination that the constitution is affected, and that the nuclei of other tumours are to be found in the other teats. After the ulcerative process has been once established the case is perfectly hopeless. Even if the nuclei of new enlargements cannot be felt, the animal will nevertheless soon perish from the development of the disease internally, or, to speak more properly, from metastasis of the disease.

The only effectual mode of treatment is to remove these nuclei as soon as they are perceived, and before the system can be contaminated.

The cause of cancer in these cases is the comparative inactivity of certain parts, which nature intended to be actively and usefully employed. At every period of estrum in the bitch, there is a secretion of milk in the teats, which not being drawn away in the natural process of suckling, the fluid is long detained in the teats, irritates them by its presence, and produces this specific and fatal inflammation. Hereditary predisposition, over-feeding, and sometimes external violence, are sources of scirrhus tumours.

Cancer is found also in the vagina and uterus of the bitch, and occasionally canker in the ear assumes the character of true cancerous ulcer. All applications and operations are perfectly useless.

In the teats of the cat, cancer establishes itself to an extent that

would scarcely be thought credible. The whole of the external surface of the belly often presents one horrible mass of cancerous ulceration.

The horse is subject to cancer in the eye, and the scrotum externally; and the kidney, and the vagina, and the uterus, and particularly the pyloric orifice of the stomach internally. The symptoms by which the presence of internal cancer might be indicated are not known, and if they were, no medical skill could arrest the evil.

Cattle and sheep are subject to cancer of the jaw, the eye, the scrotum, and the udder externally; and of the pyloric orifice of the fourth stomach internally.

CANCER, the Crab, the fourth constellation of the zodiac, being one of those in Ptolemy. From the end of January to that of April, its time of coming on the meridian in this country varies from midnight to six in the evening. In the obsolete and useless division of the ecliptic into signs, Cancer is the part of that circle between 90° and 120° from the vernal equinox. The surrounding constellations are Hydra, Leo, Lynx, Gemini, and Canis Minor.

There are edifying mythological stories in Hyginus, &c. [ZODIAC.] The mythology of the minor constellations is hardly worth a reference. There are no stars of conspicuous magnitude in this constellation. The following are the designations of the brightest:—

α	65	3055	4

CANDELABRUM, an article of furniture used by the ancients both in their public edifices and private dwellings. The candelabra used in public edifices were usually of a greater size, and made with a large cup at the top to receive a lamp or sufficient unctuous material to feed a large flame: they were also employed for burning incense in the temples. Candelabra have been found in the private dwellings discovered at Herculaneum and Pompeii, consisting of tall slender bronze stands, sometimes with a flat circular top. In other instances

[Bronze Candelabrum from [A, moveable Candelabrum; C, moveable shaft; 1 l, connecting joints of the legs.] Herculaneum.]

they have a vase-like top, also flat, or with a socket, and projecting feet at the bottom of the long stem on which the light was placed.

The base is usually triangular, with the foot of a goat, lion, or griffin at each angle; and the shaft terminates in a capital which supports the tray or socket. The flat part at the top was called by the Greeks *pinakion*, or "little tablet" (Πινάκιον or Πινάκιδιον). Candelabra were among the richest ornaments of public and private buildings. They were constructed of bronze, iron, marble, terra-cotta, and wood; but

[Marble Candelabrum, from Piranesi's works.]

some are mentioned as being made (or covered) with the precious metals. Their forms were varied in all possible ways to please the taste of the wealthy: sometimes the stand was a human figure,

holding in one hand the cup or receptacle of the oil, and ornamented with gilding:—

"Si non aurea sunt juvenum simulacra per aedeis
Lampadas igniferas manibus retinentia dextris,
Lumina nocturnis epulis ut suppeditentur."

(Lucretius, ii. 24.)

These candelabra or lamp-stands "in their original and simple form, were probably mere reeds or straight sticks fixed upon a foot by peasants to raise their light to a convenient height. . . . Sometimes the stem is represented as throwing out buds; sometimes it is a stick, the side branches of which have been roughly lopped off, leaving projections where they grew. . . . Some have a sliding shaft, like that of a music stand, by which the light might be raised or lowered at pleasure." The annexed cut represents two bronze candelabra, one of a simple form, the other in some measure complicated. "The base is formed of three goats' legs, each having a ring at each end, 5, 5, 5. The centre piece is attached to the side pieces by rivets, 3, 4, round which these rings are allowed to turn, so that the three lie either parallel when the candelabrum is taken to pieces, or may be made to stand at equal distances in the circumference of a circle, in which case the two exterior rings lap over each other, and are united by a moveable pin. The end rings, 5, 5, 5, which are placed at different heights as shown at *h*, will then be brought into the same vertical line; and the round pin, *c*, which terminates the stem, passes through them and is secured by a pin, 7, passing through the hole, 8, which keeps the whole tight." The shaft is square and hollow, and surmounted by two busts. Within this lower shaft a smaller shaft, *e*, plays up and down, and is fixed at any desired height by the pin, *f*. ('Library of Entertaining Knowledge'—'Pompeii,' vol. ii. pp. 295-6.) According to Pliny ('Nat. Hist.' xxxiv. 6) the finest candelabra were made at Tarentum and Ægina.

The annexed cut of a marble candelabrum is from Piranesi's work, 'Vasi, Candelabri, Urne, Tripodi, ed altri Ornamenti Antichi,' 2 vols. fol. atl., Romæ, 1778. In these works excessive richness in the design and delicacy in the execution are often combined. Two exquisite works of candelabra, carved in marble, are preserved in the Radcliffe Library, Oxford. The fragments of which they are composed were found in the villa of Hadrian at Tivoli, and were presented to the university of Oxford by Sir Roger Newdigate.

[Small Candelabra, from the Townley Collection in the British Museum.]

It appears that a smaller kind of candelabrum was used as an altar. (See bas-relief engraved in the 'Museo Chiaramonti,' vol. i.; also p. 56, note 24. The plates xxxvii., xxxviii., xxxix., xl., vol. vii., 'Museo Pio Clementino and Chiaramonti,' contain representations of ancient candelabra; see also the dissertation of Ch. Monsignor Gaetano Marini,

'Sopra gli Usi de' Candelabri.') The marble candelabrum in the Townley collection of the British Museum is about four feet high, with a representation of a large flame on the top. In the Townley collection there are also several bronze candelabra from twelve inches in height to upwards of five feet, and of various patterns. They are mostly flat on the top, although some are formed with a cup-like top, as if for a large flame. One has a spike to receive a clay lamp, with a hole in the centre. There is also one formed upon the principle of the lamp represented in the cut, so that it can be raised or lowered at pleasure. In all, there are about seventeen lamps, of which some of the annexed engravings are representations. In the 'Museo Borbonico' are several representations of bronze candelabra found in Herculaneum and Pompeii.

CANDLE MANUFACTURE. Candles are commonly made of tallow; but superior kinds are made of bleached wax, of the purified head-matter of the spermaceti whale, or of a composition of purified tallow and wax. Within the last few years, the concrete matter from which the more fluid portion of the oil of cocoa-nuts has been separated by pressure has been used for making candles; and some manufacturers have separated the fatty from the oily substance of tallow, and have used the former alone, which is called *stearine*, for the purpose. Indeed the careful analysis of tallow and other fatty substances has recently added largely to the list of materials for candles, and to the scale on which the manufacture is conducted, as we shall show further in a later paragraph. The form of a candle is always cylindrical, and a fibrous and combustible substance called a wick always occupies the centre of the cylinder throughout its length.

The process by which light is produced from the combustion of a candle or a lamp is the same in both cases—with this difference, that the solid matter of the candle must be rendered fluid by the heat of the wick previous to its conversion by the continued application of heat into inflammable gas. In all cases the office of the wick is merely mechanical: serving in the first instance by the heat given out during its combustion to fuse that portion of the tallow or wax to which it is more nearly applied, and then to take up through its fibres the fluid matter, which is thus prepared by minute division or separation for decomposition and combustion.

It is essential to the goodness of a candle that the size and substance of the wick should be adapted to the substance of the candle. If the wick be too thin, it will not be capable of absorbing the fused portion of the candle so fast as it is melted, and this unabsorbed portion will consequently run down the side of the candle and be wasted. If, on the other hand, the wick should be too large, perfect combustion will be impeded through the want of air in the middle of the wick, and the melted fatty substance being less completely decomposed will pass off unignited in the form of smoke; in this case, too, the light will be partially impeded by the body of the wick. Candles made of wax and of other matters which fuse less easily than tallow burn longer than tallow candles, and yield a purer and steadier light. The less fusible matter requires a smaller wick to act as its carrier and to place it in circumstances favourable for combustion; and this smaller wick being less capable than the more substantial wick of a tallow candle of supporting its own weight, the extremity falls out of the perpendicular, and being brought into contact with the oxygen of the atmosphere, is consumed. The wick of a wax candle, consequently, requires no snuffing, as that of a tallow candle does, in order to ensure the brilliancy of its flame; neither does it occupy so large a space in the centre of the flame, and thus intercept the rays of light given off during the combustion. In what way modern improvements have rendered possible the manufacture of tallow or common candles which "require no snuffing," will be explained presently.

There are two ways of making candles, which are distinguished as *dipped* or *mould* candles according to the method employed. Dipped candles are made as follows:—Wicks made of spun cotton are selected of a size proper for the intended diameter of the candle, and are cut into the requisite lengths by a simple and convenient machine, being first doubled and twisted so as to leave a loop at one end. Into this loop a smooth cylindrical stick half an inch in diameter and about three feet long is inserted; and several of the cottons or wicks, being so treated and disposed at regular intervals on the sticks, are ready to receive their external coating of tallow. The number of cottons ranged upon each stick varies according to the size of the candles to be made, it being usual to place such a number as, when the requisite quantity of tallow has been attached, will weigh two pounds: that is, if candles, eight of which will weigh a pound, are to be made, sixteen wicks are ranged upon each stick; if six are to make a pound, then twelve wicks are used; and so on. The tallow, being previously melted and strained, is placed in a kind of trough, into which the wicks are dipped three times for the first 'lay;' after being kept a short time over the trough for the wicks to drain, the sticks are placed on a rack from which the candles hang freely, and are thus allowed to harden. The same process is repeated a second and a third time and oftener, according to the required weight of the candles. During the operation the tallow in the trough must be stirred from time to time, and fresh tallow supplied, the whole being kept in a proper state of fluidity by the external application of a brazier or a bath of hot water. In some of the large establishments, the number of candles dipped at once is very considerable. In making (to take

an example) the candles called 'twelves,' that is, twelve to the pound, there are in the first place twenty-four wicks hung on each broach or stick; thirty broaches are ranged side by side, and form a group called a 'frame;' and thirty-six of these frames are attached to a machine revolving on a vertical axis. The number altogether thus amounts to $24 \times 30 \times 36$, or 25,920. In front of such a machine is a vessel of melted tallow; the thirty-six frames are each in turn brought round to a position directly over the vessel, and each frame of 480 wicks dipped at once. A 'wiping-board,' is, after each dipping, brought over the cistern by the movement of a lever; the ends of the wicks or candles are wiped on it, and the board rapidly re-ascends to its former position. The mode of determining when the candles have been dipped a sufficient number of times is by the use of a kind of steelyard or balance weight, indicating the total weight of all the candles on the machine. This method of dipping can of course be modified in a great number of ways; but by such a machine as is here described, a man and a boy can make nearly 26,000 'twelves' in ten hours.

Mould candles are made in cylindrical pewter moulds, one end of which is smaller than the other, to allow of the easy removal of the candles. In the simple and smaller mode of conducting this operation, from ten to sixteen of the moulds are placed together in a wooden frame, in such way that their larger ends terminate in a kind of trough common to the whole; the wicks are inserted and kept firmly in their proper places in the centre of each cylinder by strong wires. The frame being then placed with the trough uppermost, the moulds are filled with melted tallow, and are placed in the air to cool; the wires by which the wicks are fixed are then withdrawn, the superfluous tallow is removed from the trough, and the candles are pulled out of the mould.

In Morgan's beautiful mould-candle machine, however, the operations are conducted in a very different manner. The wick, instead of being cut off to the exact length required for each candle, is wound upon a reel in lengths of 100 feet. There are as many of these lengths as there are moulds. In a kind of case are enclosed a certain number of moulds, with a reel of cotton attached to each. A portion of cotton is unwound from each reel, and made to pass through a mould, the lower end of which is only large enough to admit of the passage of the wick, and is held in its place by a pair of forceps. The frame is then brought under a kind of cistern, into which melted tallow of fine quality is poured. By turning a handle, the melted tallow is allowed to flow out of as many little holes as there are moulds; and thus the moulds become filled. As the moulds fill, a man pulls the wick in each mould straight and uniform, by laying hold at the lower end. When one set is filled, the frame which contains them is wheeled along a kind of railway, and another is filled in a similar manner. As soon as the tallow has solidified, a workman disengages the forceps, and scrapes the superfluous tallow from the upper-ends of the moulds. The frame is then turned so as to bring the moulds into a horizontal position; and an ingenious piece of mechanism forces all the candles out of the moulds, and places them in a row on a flat table. The wicks in these candles are still connected with the coils of cotton wound round the little reels in the frames; but the whole are severed in a few seconds by the attendant workman. Still further to facilitate the working of this most ingenious machine, all the mould-frames are made to move along a double line of railway.

Wax candles are made by a process much more primitive than any of the above. The wicks being cut and twisted, several of them are suspended over a basin of melted wax; the wax is taken up in a large ladle, and poured from time to time on the top of the wicks; the melted wax, running down, adheres to and covers the wicks throughout their length. This is repeated until a sufficient weight of wax has been gathered upon each. After the candles are sufficiently cooled, they are rolled upon a smooth table in order to give them a perfectly cylindrical form, and are then polished.

Various plans have been proposed to obviate the inconvenience of snuffing tallow candles. One of the most ingenious of them was the subject of a patent in 1799. This plan consisted in making the candle a solid cylinder throughout without any wick in the centre, and applying on the top of the candle a very short wick which acted in the same manner as the short wick of a lamp. Two different methods were employed for keeping this wick in contact with the top of the candle during its combustion. One was to attach the wick to a small metallic frame or ring which was placed round the top of the candle like a collar, and was of such a size as to admit of its moving freely on the candle, so that it sunk in proportion as the matter of the candle was consumed. A cross piece, in the centre of which a socket was made for the insertion of the wick, kept the latter in its proper position, and prevented the undue sinking of the frame. The other method was that of attaching the wick to an immovable vertical rod which formed part of the candlestick, and of keeping the top of the candle in contact with the wick by placing its lower end upon a spiral spring which constantly pressed the candle upward against the frame that contained the wick. It is probable that one principal cause of the failure of these contrivances arose from the nature of the substance of which the candles were made; the unconsumed carbonaceous matter would form a crust upon the wick which would occupy in part the place of the frame, and thus to a considerable degree cause the same inconvenience as the ordinary wick.

The construction of candles requiring no snuffing is, however, now among many novelties successfully practised. These novelties are, indeed, singularly numerous. Patents have been obtained for candles made of palm oil, which is solid in our climate though liquid in Africa. Stearine and margarine are also employed for this purpose. *Palmer's* candles are distinguished chiefly by the use of a wick which, bending out to the hottest part of the flame as it burns, consumes without the necessity of snuffing. But the chief feature in *Palmer's* patents is the use of a candlestick which maintains the candle always at the same height; there is a spring beneath the candle, which presses it upwards with such force, that the top of the candle is always maintained on a level with the top of the candlestick, the wick alone protruding. A kind of candle lamp was introduced a few years ago, in which solid tallow is placed within a lamp, and melted as it is required for burning. One of the patents obtained by Mr. *Palmer* relates to several improvements in the manufacture of wicks for candles. The first is the formation of helical or spiral wicks, consisting of a number of strands bound together by cross gimp; with one strand stiffer than the rest, to retain the wick in its proper position. The second form consists of cotton cord, twisted hard and firm. The third is the formation of wicks plaited on a wire, which wire is afterwards withdrawn to leave a space for capillary action of the melted tallow. The fourth is for coating one of the strands of a wick in a metallic envelope, by dipping it in melted bismuth. Another of *Palmer's* patents relates to the use of a paste of borax, bismuth, flour, and charcoal; when applied to the *sides* of wicks, in a stripe or line, it is said to facilitate combustion, and to cause the wick to burn out of the flame.

Mr. *Maudslay* has patented a remarkable machine for making candles by a sort of tube-drawing process, something akin to the Italian mode of making *macaroni*. The tallow or composition is brought to a soft warm paste-like state, and in that state is forced through a tube kept cold by immersion in water; it gradually solidifies during its passage through the tube (which is of considerable length, and is coiled round a circular vessel), and is discharged into water, where it at once assumes a solid form. At one particular point before the tallow has solidified, an end of cotton wick is introduced into the tube, and is drawn in and enveloped by the tallow as it passes. The theory of the machine is such that it could produce an *endless* candle, which may be cut by simple machinery to any given length. The machine is remarkably novel and ingenious in its arrangements.

The Patent Candle Company's works at Vauxhall and Battersea are interesting, as showing the application of chemistry and of mechanism on a large scale to this manufacture. The cocoa-nut oil is chiefly procured from Ceylon, but the palm-oil (which is the chief ingredient in the patent candles) from Africa. The palm-oil reaches this country in a semi-solid state. It is first liquified by passing a steam-pipe through it; then converted by chemical processes into a colourless concrete mass; and then cut by a rotatory machine into slices, which are placed one upon another, with cocoa-fibre mats between them, and iron plates between the mats. These bundles are taken to a room where are powerful hydraulic presses, worked by steam power; and this immense pressure is applied, first cold and then hot, to force out the oleic acid from the palm-oil, leaving the solid stearine behind. This stearine, after being again liquified, is in a fit state for use in making candles, which is effected by the patent moulding machine. The company spin their own wicks (29 miles of which form the preliminary "cottoning" of one machine), and conduct several other subsidiary arrangements on a large scale. One of the many patented novelties which have been brought forward at the Vauxhall works, is a curious method (introduced in 1856), of casing night-lights with a hard material. Stearic acid and white wax are dissolved in spirits of wine; and the night-lights, or any other kinds of candle, are dipped in the melted composition. They come out with a hard film, which dries at once. Or the solution may be poured into the metal moulds for mould candles, and then quickly emptied out; it leaves a film lining the inner surface of the mould. The different kinds of candles manufactured at the Vauxhall works, chiefly owing to a skilful chemical analysis of various sorts of tallow, fat, and oil, by Mr. G. F. Wilson, are singularly numerous. These celebrated candle-works are probably the most extensive in the world. Besides large establishments at Vauxhall and Battersea, the Company are owners of another near Birkenhead. Mr. G. F. Wilson, manager of the company's works, gave the following account of the working arrangements in 1856. "In the month of October, 1840, from which time I can speak from personal knowledge, we employed 74 men and 10 boys, and manufactured about 20 tons of cocoa-nut candles, value 1590*l.*, and about 12 tons of stearine and composite candles, value 1227*l.*, per month. In the corresponding month of 1855, we employed 1098 men and 1191 boys and girls; and manufactured of stearine and composite candles and night-lights, about 707 tons, value 79,500*l.*, per month." They have, or have had, also establishments in Africa for procuring and preparing the palm-oil.

Candles are occasionally made of such composition as to aid the healing art. The "medicated candles," employed more frequently on the continent than in England, are so prepared as to diffuse the active principle of certain volatile substances through the air of a room; or to act as a fumigator. "Mercurial" candles are made by a combination of sulphuret of mercury with wax; they are burned under a glass

funnel, which has an orifice at the top, so shaped as to bring the fumigation to bear on a diseased part.

Without deeming it necessary to describe any of the innumerable forms of candlestick, either as articles of manufacture or as artistic productions, we may say a word concerning the numerous curious little pieces of mechanism patented within the last few years, having for their principal object the mode of adjusting candles in candlesticks. One consists of a candle shade constructed in a circular ring, which ring is suspended from a conical cap resting on the top of the candle; as the candle burns this cap sinks with it, and by that means, the shade maintains a constant level relatively to the flame of the candle. Another little piece of apparatus consists of a wire-frame for supporting a shade, and which is itself supported by having a sort of circular spring hoop, which clasps the candle. Many varieties of wedges and springs have been devised for fixing candles into the candlesticks. An ingenious self-acting extinguisher for candles was invented a few years ago, but we believe not patented. A steel spring clasps the candle firmly within its jaws: and the extinguisher is hinged to the handle of this spring by a bent arm. A wire projects from the arm of the extinguisher, and thrusts into the solid part of the tallow of the candle. When the candle has burned down so as to soften the tallow around the wire, the latter slips aside by being no longer able to maintain its position; and the extinguisher falls over the flame of the candle. By adjusting the wire to any particular distance below the wick, the candle can be extinguished after any pre-arranged lapse of time.

The extent of the candle manufacture in this country is not known, since the removal of the excise duty in 1832; in that year the quantity taxed was about 120 millions of pounds. So far as regards export (chiefly stearine, or hard candles, common candles being ill-fitted for exportation, except to very cold countries), the following figures have been exhibited:—

1856	6,038,881 lbs.
1857	5,605,335 "
1858	3,061,761 "

The years 1856-7 were, from exceptional circumstances, above the average.

CANDLEMAS, the popular name for the Feast of the Purification of the Virgin Mary, February 2nd, derived from the lights which were then distributed and carried about in procession. These lights, it should seem, were carried more immediately in allusion to the prophetic words of Simeon, who, speaking of the Infant Saviour, presented in the temple at the same time, said he was "a light to lighten the gentiles." *Alcuin*, 'De Divinis Officiis,' p. 231, says, the candles at the purification were an exchange for the lustration of the pagans. From this ceremony of purification the present religious ceremony of the churching of women after child-birth arose.

'The Doctrine of the Masse Booke,' &c., from Wyttenburge, by Nicholas Dorcaster, 8vo, 1554, preserves the prayer for "the hallowing of candles upon Candlemas Day." The candles, having been sprinkled with holy water, were lighted and distributed. They were considered to possess a virtue sufficiently powerful to frighten away devils, and to be a charm against thunder and lightning. *Stow*, in his 'Annals,' fol., 1631, p. 595, says, "On the 2nd of February, 1547-8, being the Feast of the Purification of our Lady, commonly called Candlemasse Day, the bearing of candles was left off throughout the whole city of London."

"There is a general tradition," says Sir Thomas Browne ('Vulgar Errors,' book vi. c. 4), "in most parts of Europe, that inferreth the coldness of succeeding winter from the shining of the sun on Candlemas Day." A similar notion still prevails in some parts of this country, though it is rather that the succeeding spring will be a cold one.

Candlemas Day was also called Christ's Presentation, the Holiday of St. Simeon, and, in the North of England, the Wives' Feast Day.

It is stated by the author of the 'English Festyvall,' that the practice was borrowed from a pagan custom at Rome, of bearing lights in honour of the god Mars, and that pope Sergius commanded that, instead of the heathen deity, the same ceremonies and the same day should be consecrated to the Virgin Mary. (Brand's 'Popular Antiquities,' edited by Sir Henry Ellis, 1841; Brady's 'Clavis Calendaria.')

CANDY. A candy is generally a mass of sugar, to which a peculiar quality has been given by boiling with it certain other substances. These substances may be chosen for their taste, their aroma, or their medicinal properties, and may be used in any one of the forms of infusion, decoction, tincture, juice, or powder. In such case, the sweetmeat or confection is allowed to cool into flat cakes, or is cast into moulds. Another form of candy is that in which the vegetable substance, whether a fruit, a peel, or any other, is so treated as to retain its shape, but at the same time to assume a semi-transparent appearance, in consequence of being thoroughly saturated with sugar. In one or other of these forms we find candied almond, angelica, apricot, caraway, citron, figs, ginger, horehound, lemon-peel, orange-peel, orange-flowers, &c. Candied sugar, or sugar-candy, is simply sugar rendered very pure by crystallisation. It is brown, white, or red in colour, according as it is prepared from raw sugar, loaf sugar, or from a syrup coloured by cochineal. Besides being used as a sweetmeat, sugar-candy is useful to keep the throat moist during coughs, and is blown into the eyes as a remedial agent in certain cases.

CANELLA ALBA, a tree growing on the coast of many of the West

India islands, particularly Jamaica, also on stony hills; and in woods of the mainland of South America. It was called by Linnæus, at one time *Laurus Winteranus* ('Spec.' ed. i. p. 371), and at another *Winteriana Canella* (Lin., 'Sp.' 636). It is referred to a small tribe called *Canelleæ*, related to *Guttifera*. The bark of the young branches of this tree, freed from its outer rind, is the *Canella alba* of the shops (called also *Costus dulcis* and *Costus corticosus*, and *Cortex Winteranus spurius*, or False Winter's bark). Owing to its white appearance, it has received the name of white cinnamon, which it also resembles in smell as well as cloves. The whole tree is very aromatic, and when in flower perfumes all the neighbourhood; even the dried flowers, when softened again in warm water, have a fragrant odour, similar to that of musk. The smell of the leaves resembles that of laurel. The bark is brought to Europe in rolls or quills of two or three feet long, or short broken pieces of from a-half to one and a-half inch in diameter, and a half to one and a-half line in thickness. The outer surface is either reddish-yellow or verging to a whitish-yellow; the inner surface smooth, resembling the external in colour. The taste is at first agreeably aromatic, and somewhat bitter; afterwards acrid and peppery.

According to Petros and Robinet, it contains a very acrid aromatic volatile oil (which Sloane says is heavier than water, Henry and Cartheuser say is lighter, and which is employed for the adulteration of oil of cloves), a bitter extractive, a resin, a sort of manna sugar, called *canellin*, gum, albumen, and starch. It is rarely, if ever, adulterated, but is itself often substituted for the *Drymis Winteri*, or true Winter's bark. The two may be distinguished by the following characters:

CANELLA ALBA.	WINTER'S BARK.
Of a pale orange or ash colour.	Gray or reddish gray.
Fracture whitish, marbled.	Fracture compact or foliaceous, gray at the circumference, red towards the centre, with a very obvious line of demarcation.
Internal surface covered with a whitish pellicle.	Internal surface of a deep red or black.
Odour agreeable, resembling cloves.	Odour peppery, and, when powdered, turpentine-like.
Taste acrid, bitterish.	Taste sharp, burning, intolerable.
Powder white.	Powder grayish yellow.
Watery infusion pale.	Watery infusion red.

The cold infusion of each, treated with the following re-agents, conduct themselves thus:

	TINCTURE OF GALLS.	MURIATE OF IRON.
Canella Alba.	Slight whitish disturbance.	Brown yellow discolouration.
Drymis Winteri.	No action.	Dark brown discolouration.
	SULPHATE OF IRON.	NITRATE OF BARYTES.
Canella Alba.	No action.	No action.
Drymis Winteri.	Precipitate.	Precipitate.

Alcohol is the most appropriate menstruum: water takes up the less powerful principles only. As the infusion is not affected by many articles which it is often desirable to give at the same time, it affords an eligible vehicle for these, such as tincture and infusion of galls, lime-water, tartar emetic, and the salts of iron and mercury. It may also be given in powder. From its aromatic properties it is likewise a suitable adjunct to mere bitter infusions, such as those of gentian. In the dyspepsia, attended with constipation, of sedentary people, along with sulphate of iron, aloes, and sulphate of potass, it is a most efficacious medicine. This is an improved form of a powder still popular, properly *Hiera Picra*, corrupted into *Hicry Picry*.

Canella alba is used both by the Caribs and the Negroes in the West Indies as a spice and as a preserve, thought to be useful against scurvy. In Martinique the berries furnish a liqueur much prized.

CANES VENATICI, the Hounds, a constellation added by Hevelius, who called the nearest to the pole Asterion, and the other Chara. They are held in a string by Bootes, and are surrounded by Bootes, Coma Berenices, and Ursa Major. [COR CAROLI.]

The following are the designations of the two principal stars in this constellation:—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
<i>d</i>	8	4235	4
<i>a</i>	12	4346	2.5

CANG, CANQUE, or KEA, a large wooden collar, used as an instrument of legal punishment by the Chinese. It is a species of walking pillory, fitting close round the neck of the culprit, and of such a weight that he can carry it, though with pain and difficulty. The weight is proportioned to the nature of the offence; but the cang most commonly in use weighs from fifty to sixty pounds. When it is fastened round the neck, long slips of paper are pasted over the two parts of the cang, which opens and shuts like our stocks; on these papers the mandarin puts his seal, so that the parts cannot be separated or the criminal relieved without its being perceived. The crime for which he suffers and the duration of his punishment are then inscribed on the cang in large letters, and the officers of the police parade the criminal through the town, after which he is left exposed in some

much-frequented street or square, or at one of the gates of the city. As the cang prevents his making any use of his hands, he must be fed by others. M. Huc, in 'L'Empire Chinois' (Paris, 1854), relates that on one occasion, at Fou-ki-hien, he and his companion found a man suffering under the cang, who implored their forgiveness. They examined the slips of paper, and found he was "condemned to fifteen days of canque, the nights not excepted, for the offence of disrespect towards the strangers of the West;" and they succeeded in procuring his release from a punishment for the offence of calling them by a common nickname, and of which they had been entirely ignorant. The Chinese consider this species of punishment very infamous and degrading. Correct representations of the instrument and the manner in which it is applied are given in Sir George Staunton's account of the Chinese, and in the work of Sir J. F. Davis. The cang, called by them Tahtakulah, was formerly in use among the Turks.

CANIS MAJOR, the Greater Dog, a constellation which contains SIRIUS, the brightest star in the heavens, called also the Dog Star. To this article we shall refer all historical and mythological information connected with this constellation, it being in fact the star, and not the constellation, about which we shall have to speak.

This constellation is directly found by the bright star Sirius, which is in the continuation of the line drawn through the belt of Orion. The surrounding constellations are Argo, Monoceros, Orion, Lepus, and Columba Noachi. At the end of January, Sirius is on the meridian at midnight.

The following are the principal stars in this constellation. The letters within parentheses are from Baily's *Flamsteed*:—

CANIS MINOR, the Lesser Dog, a constellation situated above the Greater Dog, and distinguished by a remarkable star of the first magnitude, PROCYON, which see for information connected with the history of this constellation. It may be found in the heavens thus: draw a line through Orion's belt and Sirius; a perpendicular to this line from Sirius upwards will pass through Procyon, which is too large a star to be mistaken. It is also nearly in the line joining Sirius and Pollux, about midway between them.

The following are the principal stars in this constellation:—

CANKER. This term is applied, perhaps not with strict propriety, to a very serious disease of the foot of the horse. The horn having been separated from the sensitive portion of the foot, a fungous substance is produced instead of new and healthy horn. The treatment, however, is exceedingly simple. Every portion of horn that has begun to detach itself must be removed. Some superficial caustic must then be applied in sufficient quantity to repress the growth of the fungus, and to rouse the exposed surface to healthy action, but not to eat into and corrode the foot. The butyr (protochloride) of antimony is the best agent for accomplishing these purposes; for, being speedily decomposed by the moisture of the part, it can only act as a superficial caustic. The fungus having been repressed, the Friar's Balsam may succeed as a mild stimulant to the secretion of good horn. No ointment should touch the cankered foot; but pledgets of soft and clean tow should be placed over the sore, and bound firmly upon it, making as equable a pressure on every part of it as can possibly be effected. The foot should be dressed at least once in every day, and kept as dry as circumstances will allow.

Inflammation of the internal part of the ear of the dog will sometimes produce a fungous ulceration, to which also the term *canker* has been applied. A dog may be observed to be continually shaking his head, or scratching his ear, or carrying his head on one side. If the part is examined, some degree of redness or enlargement of the irregular projections on the inside of the ear will be seen. This will generally yield to a few washings with warm soap and water; but should actual ulceration have commenced, a drachm of the extract of lead should be added to half a pint of a decoction of the heads of white poppies, and this substituted for the soap and water. The

inflammation beginning to subside, a scruple of alum should be added to this lotion, in order to dry up the ulcer; but nothing stronger than this should ever be applied, and even the alum should be cautiously added, in proportion as the dog is able to bear it. Purging and alterative medicines will be useful auxiliaries.

If the case is obstinate, and the ear begins to be extensively ulcerated, and the ulcer spreads over the flap of the ear, a seton should be inserted in the poll precisely between the ears, and extending from ear to ear. All water-dogs are particularly liable to this species of canker.

There is another variety of canker belonging to the flap of the ear, to which the hound and the pointer are especially subject. It is either the consequence of that which has just been described, or exists independently of it. A sore appears on the edge of the flap of the ear of a true cankerous nature, and corrodes the very cartilage. The treatment of this also is simple and effectual. The ears, or at least the diseased ear, must be confined by a cap of leather or strong calico, for while the dog can flap and beat his ear, it is evident that the sore can never heal. This being contrived, a strong ointment of alum or white vitriol (sulphate of zinc), or both combined, should be well rubbed on the sore morning and night. The simple alum ointment should first be tried.

Sportsmen too often round the ears of the dog; that is, they cut off the diseased parts. This disfigures the animal, and is rarely effectual. Either a new ulcerative inflammation is set up by the operation, or the whole ear having been inoculated and empoisoned by the discharge from the old wound, the peculiar ulcer of canker speedily appears again as extensive and as obstinate as before.

CANNABIN. This name has been given to a resinous substance of unknown composition, extracted from hemp. It is highly poisonous.

CANNIBALS, *Anthropophagi*, or men-eaters. In the *Odyssey* of Homer we have the story of Polyphemus devouring human flesh; and in Herodotus, the Massagetæ (i. 216) are said to eat their aged parents. The Padæi of India (Herod. iii. 99) were in the habit of killing and eating their relations when they fell ill; a story which some would reject with as little show of reason as others would believe it. Modern facts, the truth of which is put beyond all doubt, confirm the statements of Herodotus. Among the ancient Tupis of Brazil, when the Pajé (chief) despaired of a sick man's recovery, he was by his advice put to death and devoured. (Dr. Martius in 'London Geog. Journal,' ii. 199.) Herodotus (iv. 26) also says that among the Issedones, when a man's father dies, his relations come and help to eat the dead man, whose flesh they render more palatable by mixing it with that of some animal. That these facts as to cannibalism, as reported by ancient writers, are not to be hastily rejected, need hardly be remarked.

In the middle ages, it is true, these stories of cannibalism were wonderfully enlarged, and people who had not yet embraced Christianity were pretty generally set down as anthropophagi. When the Lombards invaded Italy at the end of the 6th century, it was reported of them that they ate human flesh; and a century later the same aspersions were cast on the Slavonian tribes. It became the fashion to bandy the accusation between enemies; thus, during the Crusades, the Saracens said the Christians ate human flesh, as well as the unclean flesh of swine, while the Christians on their side maintained that the Saracens ate men, women, and children, and were particularly fond of a sucking Christian babe torn fresh from the breast of its mother. The giants and ogres of our nursery tales are only the Saracens of the holy wars seen through the magnifying glasses of tradition and romance.

It does not much surprise us that in those rude ages men should try to fix a revolting practice on their sworn foes, but we can hardly understand why the minstrels of the Christians should convert their most approved heroes into cannibals, and praise them for the quantity of infidel flesh they devoured. Yet our Richard I. is put in this predicament by the author or authors of the romance of 'Richard Cœur de Lion.' According to the poem, the first symptom of the king's recovery from a dangerous sickness at Acre was a violent longing for pork, and as pork was difficult to procure in a Mohammedan country, his cook dressed him a Turk's head, of which Richard ate with good appetite, and felt himself quite well in consequence. After some more repasts of the same kind, he is made to say:—

"King Richard shall warrant,
There is no flesh so nourissant
Unto an English man,
Partridge, plover, heron, ne swan,
Cow ne ox, sheep ne swine,
As the head of a Sarezyne."

The old travellers abound in stories of cannibalism, which we may almost invariably pronounce to be false. Few persons would now credit that the Indians and Chinese sold human flesh in the market, or that the grand khan of Tartary fattened his astronomers and magicians with the carcasses of condemned criminals; but Marco Polo, the Venetian, who resided in China and traversed the Indian seas in the 13th century, in speaking of a people in Sumatra (the Battas), and of the fierce inhabitants of the group of islands called the Andamans, relates no more than has been confirmed by modern travellers.

In the 16th and 17th centuries, the wildest accounts of the natives of the newly-found lands in America, and of places on the African

coast recently brought within the range of European commerce, were circulated by ignorant sailors and believed by credulous writers. In many of these cases there was a small matter of truth at the bottom, which was wonderfully magnified by fear and credulity. It was reported, for example, that the Caribbees preferred sucking infants to all other food—that the Peruvians kept mistresses for the purpose of breeding children for their tables, and fattened, killed, and ate these women when they were past child-bearing—and, not to mention numerous other instances, that the Anzigas of South Africa exposed human flesh for sale in their shambles, as we do beef and mutton. The industrious old compiler, Purchas, says he was assured of the last-mentioned fact "by John Battell, of Essex, a near neighbour of mine, and a man worthy of credit." Even in modern times, the inhabitants of Van Diemen's Land have been set down as cannibals, in Dentrecaesteaux's Voyage, because the bones of a kangaroo were mistaken for those of a young girl. Mr. Kane, who recently resided some time among the Indian tribes of Canada, speaks of particular families in several tribes as being confirmed cannibals. But he says these Weendigoes, "eaters of human flesh," as they are called, are always made to encamp apart from the main body of the tribe, though they are treated with respect and a sort of reverence. With them, as far as he could ascertain, the practice always originated in extreme hunger; but it was believed that the taste once acquired the Weendigo was afterwards wholly unable to resist its indulgence. (Kane, 'Wanderings of an Artist among the Indians of North America,' Lond. 1859.) This is the most recent testimony to the prevalence of cannibalism.

Many persons, who admit that human flesh has been eaten under the pressure of necessity, as in sieges, shipwrecks, &c., still maintain that there is no evidence of any race or people eating human flesh from choice. But proof the most conclusive has been brought against the New Zealanders, who devoured their captives taken in war in the most open manner. It is also stated on good authority that even the New Zealanders who had been humanised by intercourse with Europeans and their voyages in European ships, resumed their habits of man-eating as soon as they returned home. That the horrid practice lasted long in New Zealand is proved by a captain in the French navy, who stayed some months at the island. (See 'Voyage de la Favorite, de l'année 1830 à 1833,' par M. Laplace.) The practice has now become obsolete.

The Battas of Sumatra are undoubted cannibals, and there are still native tribes in Guiana, in South America, who fatten and eat their prisoners. ('London Geog. Jour.,' vol. ii. p. 70; but compare vol. ii. p. 240.)

We refrain from offering any conjecture as to the origin of cannibalism. No explanation we have seen appears to us satisfactory.

CANNON, the generic term for large guns. Under this head will be described the method of making cannon in the foundry. Cannon were originally composed of strips of metal bound round and kept together with iron rings; to this succeeded the improvement of casting them in one piece, which was done at first by casting them hollow by means of a core. [ARTILLERY.] At the beginning of the 18th century it was a debated question among several artilleryists, whether cannon should be cast hollow or solid. In 1749 a founder of Geneva, of the name of Maritz, informed the court of France that he had discovered a method of boring guns and mortars that had been cast solid; he was at once employed, and worked first at Lyon and then at Strasburg, and the guns were considered very satisfactory, so much so, indeed, that from that time guns have usually been cast solid, and afterwards bored. In casting guns hollow, it was found that they were much weaker in some parts than in others, in consequence of the irregularity of the cooling of the metal; whereas, when they are cast solid, the outside, which cools first, has a much closer and sounder grain, and the centre, which is afterwards bored out, is unequal and spongy in parts.

Cast-iron ordnance for the government in England is principally made at private foundries by contract; the Low-Moor Company, whose works are at Blackford, in Yorkshire, and the Messrs. Walker, of the Gospel Oak Foundry, in Staffordshire, being the principal contractors. Within the last few years an iron foundry has been established in the arsenal at Woolwich, from which a few guns are turned out, principally as a check on private manufacturers, and to avoid the necessity of government being wholly dependent on them.

The usual method of casting iron ordnance is this: A model representing in form, but a little larger than the piece, is made in some hard, well-seasoned wood, or else of cast-iron; the muzzle of the gun, or rather model, is continued for some feet by a solid cylinder, to form in the mould the portion for the dead-head, a waste portion, which is afterwards turned off, and is only added to ensure the whole of the metal of the gun being solid and good, and to supply the shrinkage when cooling, which is generally about .08 inch for each foot in length. A jacket or box is employed to form the mould in; this jacket is divided into about six parts in its length, each part being again divided into two parts, with flanges on each side, to connect them together by screws and nuts. The mould itself, which is composed of sand and clay-water, is made by commencing with the breach, the model of which is placed on a board, and covered with charcoal-dust and clay-water, to prevent its adhering to the mould, the jacket is then nicely adjusted at the proper distance from the model, and the interstice filled by ramming in sand and clay-water; the next piece is then put on, the jacket adjusted and filled as before, and so on till

the whole is built up. The portions of the jacket are kept slightly apart when making the mould, in order to allow for the contraction when drying. The mould is then dried gradually in a stove; when dry, the jackets being opened and the model taken out, the portions are taken to the pit, and there carefully put together again in a vertical position. A number of moulds being put up side by side, the intervals are filled in with earth or sand, and channels made to a central basin by which the metal is allowed to run in at the top of the dead-head, to this basin another channel is made from the reverberatory furnace. The metal usually employed in England is a mixture of the different sorts usually known as Nos. 2, 3, and 4 of the best cold-blast iron. To arrive at the right qualities for a gun, which are, hardness combined with toughness and strength, is a delicate operation, and requires great judgment and experience in the mixture of the different qualities of iron. The metal is melted in two or three reverberatory furnaces, according to the number of castings, with the purest description of coal, when the furnaces are tapped, and the metal run into a basin of sand, made close to the moulds, into which, when at the right temperature, it is allowed to run. The casting, after standing for twenty-four hours in the pit, is taken out, and remains for about the same length of time in the jacket, which is then released, and the mould broken off by a few blows of the hammer.

The dead-head is then cut off in a lathe, and the gun taken to the boring bench. If found to be without flaws, and sound, it is then taken to the lathe again, and turned down to its proper dimensions. It is then carefully examined inside and out, and if without faults taken to the machine for turning the trunnions; after which it is vented and finished off, either by filing or turning. The specific gravity of the iron of which guns are made varies from 7.0 to 7.2. To obtain the best quality of iron for guns, about the following proportions of iron ore are generally mixed in the smelting furnace: Black iron ore, $2\frac{1}{2}$; aluminous clay ore, $1\frac{1}{2}$; silicious clay ore, $1\frac{1}{2}$. This gives an iron not nearly so soft and crystalline as the quality known as No. 1, nor so hard and brittle as No. 4, but a mean between them, being a mixture combining some of the qualities of each.

Bronze Ordnance.—All the brass or bronze guns used in the British service are cast at Woolwich, in the foundry in the Royal Arsenal. The metal is an alloy of ten or twelve parts of tin to 100 of copper. Copper of itself, though a very ductile, malleable metal, with great tenacity, has not sufficient hardness to resist the wear and tear and chance of external injury to which a gun is exposed. Though it resists the action of gunpowder better than any other metal, shot would soon indent the bore if it were not hardened with some other metal; and tin, though a softer metal, has the property of hardening it. The specific gravity of bronze gun-metal is from 8.6 to 8.9. Bronze guns, in the same manner as iron ones, are cast solid, and with a large dead-head, by which the whole length of the gun is obtained of sound metal; the dross and impurities rising to the top, and the column of metal, by its weight, assisting to compress the lower portion and supply the shrinkage.

Bronze is not so much used in England as abroad for the manufacture of guns. In France the siege artillery has been formed of bronze on account of its lightness, and perhaps from the difficulty of obtaining good castings with the foreign iron, which, with the exception of Swedish iron, is not adapted for guns. The defect of all iron for guns, and more particularly foreign iron, except the Swedish, which is the best, is its want of elastic work and small sphere of cohesive force. The want of elastic work prevents the particles of metal, when expanded by the charge of powder, returning to their former state; and the smallness of the sphere of cohesive force makes the gun liable to burst when at all strained. The tenacity of cast-iron is influenced by the amount of carbon it contains; and as it is extremely difficult to regulate this quantity, guns, even from the same casting, vary much in their strength. The tenacity of cast iron varies from 6 to 9½ tons on the square inch, while that of bronze is 15 tons, and the sphere of cohesive force is greater; while its principal defects are its want of hardness, which causes the bore of the gun to lose its shape from the mechanical action of the gas and ball if exposed to continued rapid firing, the bore becoming enlarged and indented, and drooping at the muzzle. They are also likely to suffer from the chemical action of the gas, which has a tendency to separate the metals of the alloy,—an effect which would be increased by the addition of more tin, which, though it would harden the compound, would decrease its tenacity.

The method of forming the model employed in the Royal Arsenal at Woolwich is rather different to that described for iron ordnance. The model is formed on a wooden spindle, of a slightly conical form. This spindle, which is a good deal smaller than the required model, having been well greased to allow of its after withdrawal, is rested in a horizontal position between two supports, and has a cross handle attached to one end to turn it by. The portions of the model formed on the spindle extend from the base ring [ORDNANCE] to the muzzle and part of the dead-head, the rest of the dead-head and breach and cascable being formed separately. Plaited straw is now wound round the spindle, bringing the whole nearly to the size and form of the desired model; the object of the straw is to furnish a key for the model composition to adhere to. The model composition is now put on by hand in a moist state; it consists of sand, loam, and horse-dung,—the horse-dung being added to make it friable when burned. A modelling board, cut out to the profile, so to speak, of the gun, is placed alongside, at

the proper distance from the centre of the spindle, which being turned round, the soft composition is cut off to the required shape. Care is taken to ensure a sufficient thickness of composition over the straw, and it is laid on in three coats, each coat being dried by a charcoal fire before the next is put on. The model of the cascable is made in the same manner on an iron spindle, and a wooden patch added at the base ring for the tangent scale. The wooden models of the trunnions are then fixed on by an iron pin, and the vent-patch and dispart, if a howitzer, being added, the model is complete. It is washed over with tan-ash and water, to prevent the adhesion of the mould composition. The mould composition consists of loam, sand, and cow-hair, well mixed together with water; this, first in a wet and then in a drier state, is laid on in coats, which are strengthened with hemp fibres and iron hoops. The vent and dispart patches are removed after the first coat, and the trunnions when the mouldings are finished. After the three coats have been put on, and the mould strengthened with iron bars, the spindle is knocked out, and the straw carefully removed. A wood fire is then made inside, and the model composition becoming quite brittle is easily extracted. The mould of the cascable, prepared in the same way, and the remainder of the dead-head, having been added, the mould is raised vertically in the casting-pit, in the same manner as with iron guns. The metal is melted in a reverberating furnace, and if it be a re-casting, a small quantity, about .3 per cent. of tin, is added to replace the waste, the whole being kept well stirred with fir-poles. When at the right temperature, it is allowed to run into a channel which communicates with the moulds; and having risen to a certain height (about eight inches), the sluice-gates are opened, and the moulds filled two at a time. After remaining three days in the pit, the moulds are taken up and broken off the casting. From two to three times the quantity of metal actually required for each piece when finished is allowed to make up for dead-head, turning down, &c. The dead-head of a 24-pounder howitzer is about $3\frac{1}{2}$ feet long.

The casting is now taken to the boring department, and the dead-head cut off in a lathe. It is then put in the centering machine, the object of which is to obtain the exact centre or axis of the piece, on which all the other lathe operations depend. The piece is laid horizontally on two saddles; each saddle has a system of three slides moving inwards at a uniform rate on screws of the same pitch, two moving horizontally towards each other, the other vertically upwards. As they move at the same rate, the faces of the slides at each saddle are always tangential to the same circle, the centre of which is a drill which is moveable horizontally. When the faces of the slides all touch the outside of the casting, the drills are moved forward, and the centerings are cut.

The gun is now taken to the second lathe, and being fixed by these centerings, the muzzle and base rings, and two rings, one on each side of the trunnion, are accurately turned. This is an important operation, as on it depends the accuracy of the bore.

The trunnioning machine is now employed. The gun rests between two cones, which run into the centerings, and are moveable horizontally to suit any length of gun, and vertically to raise the gun according to its calibre to the right height for the frames carrying the cutting-tools to work on the trunnions. The frames work in and out opposite to each other, on a bed exactly at right angles to the bed on which the gun rests, and have motion communicated to them by a driving-shaft underneath. When the trunnions have been turned, the portion between the trunnions is removed by a planing-machine, from which the gun is removed to the drilling-frame, where the hole for the tangent scale is drilled, and also that to receive the bushing for the vent. As the bush does not run in vertically to the bore, the gun is tilted up to suit the drill, which acts vertically. The hole thus prepared is tapped, and a bush of pure copper with a vent two-ninths of an inch in diameter is screwed in. Copper is employed in preference to other metals, as it withstands the chemical action of powder best.

The boring is next performed, the muzzle-ring (accurately turned in the second lathe) resting in a V, and the gun receiving motion from the mandrill of the lathe; the boring-bits are fixed to the end of a boring-bar, which has a horizontal self-acting motion, or is driven forward by the hand.

The remaining portions of the outside of the gun having been cleaned off in a turning-lathe, the portions at the shoulders of the trunnions which cannot be touched are removed in the shaping-machine. It is then proved, and the driver sawn off, and the button finished with the hand.

The foregoing description applies only to the manufacture of guns at present in use. With respect to the newly adopted Sir William Armstrong's gun, the manufacture is kept strictly secret, and no precise details can therefore be given. The following account, extracted from the 'Times' of May 14th, 1859, is believed to give an accurate general idea:—

"Two hundred guns are to be made this year by Sir William Armstrong, all of them 9, 12, and 18 pounder field guns, a number quite sufficient to supply all our field artillery batteries. Before long, however, we hope to see guns of 50 cwt. which will throw a 90 lb. or 100 lb. ball a distance of five miles. Each gun is made in about three feet lengths, and on much the same principle as the twisted gun-barrels. Thin bars of the best wrought iron, about two inches broad, are heated to a white heat, and in this state twisted and welded

together in spiral rolls round a steel bar or core, smaller in diameter than the bore of the gun. Over this, when cold, another twist of the same kind is made with the spiral running in a contrary direction, and so until three or four layers have been put on, according to the calibre of the gun and the thickness required; the whole is then reheated and welded together for the last time under the steam hammer. The edges of the three feet lengths are next planed down so as to admit their joining and lapping over; and over these edges are forced on thick wrought iron rings, which, being welded down at a white heat, of course contract so as to make the joint almost stronger than if made in one piece. In the breech an opening is cut down into the chamber; but the breech itself is separate from the gun, and is worked backwards by a powerful screw. When the gun is to be loaded, the breech is worked back, and a wedge-shaped piece, fitting into the opening of the gun, lifted out, but not to admit the introduction of the charge, which is pushed forward with a ramrod at the back, working through the large screw in which the breech turns into the chamber, where the rifling begins. The wedge is then replaced, the breech screwed close by a single turn of a lever handle, and the gun fired. The operation of loading and firing can be performed, we believe, three times in one minute. Apart from the simple but effective mechanism of the breech, the great merit of this gun consists in the manner in which it is formed in spirals of metal bands, which give it such an enormous increase of strength that one-half the thickness of iron can be dispensed with. Thus, an ordinary long 32-pounder weighs 57 cwt., and requires 10 lb. of powder to throw a ball to its utmost effective range, 3000 yards. Sir W. Armstrong's 32-pounder only weighs 26 cwt., and a charge of 5 lb. of powder throws its shot $5\frac{1}{2}$ miles, or nearly 10,000 yards. In a 32-pounder of this latter kind there are no less than 44 rifle grooves, having one pitch in 10 feet, or making one complete twist round the inside in a gun of that length. A greater pitch would no doubt give greater impetus to the shot, but the risk of 'stripping' the lead was so great that it could not be attempted. The shot used are iron and cylindrical, and at first were completely coated over with lead; but this plan has just been altered, and the shot have now only two rings of lead a quarter of an inch thick and an inch and a half broad, one at the shoulder and one at the base of the cone. Both these rings are dovetailed, so to speak, into the iron shot, so as to leave about one-tenth of an inch to fit the rifling. Thus, when the cartridge is ignited, the ball is forced forward from the chamber into the narrow bore, which it fills so closely, being actually too large for it, that there is no windage whatever, and every portion of the explosive force is applied to projecting the ball."

CANON (*κανών*), a rule. The several senses in which this word is used are all derivatives from its first or original sense: and this sense it appears to have acquired, as itself a derivative from *canna* (we use the Latin form, though in fact both *canna* and *canon* are Greek terms transplanted into the Latin language), which signifies a *reed* or *cane*; such a plant as produced straight, round, smooth, and even shoots, adapted to the purpose of a *rule*; or as we say, a *ruler*, used in drawing straight lines. The word *canon* is the same with *canon*, and is applied to the instrument of war so called on account of its resemblance to a rule. The word *canon* is used in mathematics and in music; and also to express certain grammatical rules formed by the critics. But it is more particularly appropriated to *rule* in respect of things ecclesiastical, and it is in this application of it that we propose here solely and briefly to treat of it.

If it is asked why *canon* should be used for *rule* especially in things ecclesiastical, we answer that the most probable reason that can now be given is, that the word was so used by St. Paul (Gal. vi. 16). "And as many as walk according to this *rule* (*canon*), peace be on them and mercy, and upon the Israel of God."

The *rule* here spoken of was the Christian rule, the rule or law of the Christian church: and as these rules became explained or amplified in subsequent times by persons deemed of authority in the church, as by popes, bishops, councils, whether general or particular, these new rules or explications of the ancient and fundamental rules of the Christian church were designated by the term *canones* or *canons*. Of these there is a great multitude. Thus they speak of the canons of the Council of Nice, the canons of the Council of Trent, meaning the decisions of those councils on points of doctrine or discipline submitted to them. The *Apostolical canons* are canons which are supposed to have been agreed upon at a very early period in the history of the church. By some learned persons they have been referred even to the times of the Apostles, whence this name.

The collected body of these canons forms what is called *The Canon-Law*, which in other words is the law of the church, that body of injunctions regulating men's private discipline, and their social relations, which originate, not in the conferences and wills of civil authorities or parliaments, but in the deliberations of ecclesiastical courts or ecclesiastical assemblies, the members of which were ecclesiastics, and the precedents on which they acted the decrees of similar assemblies, or of other persons possessing ecclesiastical authority, or finally, of the most sacred authority of all, that of the Apostles and of the Founder of the Christian church. We may here make a slight deviation from our subject to point out the distinction between the canon law and the civil law. The former is already explained. The civil law is the political and municipal law of the Roman empire. When we hear a

person spoken of as doctor of laws, what is meant is, that he is a doctor of both civil and canon law; but the term in Great Britain is now little more than a mere honorary distinction.

Canon is also used for the *rule* of persons who are devoted to a life strictly religious: persons who live according to (religious) rule, such as praying at certain hours, and for a certain length of time, keeping themselves from marriage, eating particular kinds of meat, periodical fastings, and the like. It is applied to the *book* in which the rule was written, and which was read over to such professed persons from time to time; and since in such a book it was not unusual to enter also the names of persons who had been benefactors to the community, which names were recited from time to time with honour, and they were held and reputed to be holy persons or saints (*sancti*), the entry of such names formed what is meant by *canonisation*, though in later times, when it was found that saints multiplied too fast, when every small religious community added any benefactor to their list, the term became confined to such persons as had their names enrolled in the great imaginary volume of which the head of the church was the sole guardian. It was also applied to *persons* who lived under a rule; as the Augustinian canons, persons who adopted the rule of Saint Augustine. And here the distinction is to be observed of *regular* and *secular canons*. The regular canons were persons who were confined to their own monasteries, where they practised their rule; the secular canons were persons living indeed a religious life, or one according to some prescribed Christian form and order, but who nevertheless mixed more or less with the world, and particularly as discharging the various offices of Christianity for the edification and benefit of the laity. This was the species of canons that are found in the cathedral churches, or in other churches called conventual, as at Southwell in Nottinghamshire, which were all churches of very ancient foundation, the centres of Christianity throughout an extensive district. There they lived a kind of monastic life under the presidency generally of a bishop: but issuing forth from time to time to introduce the light of Christian truth into districts into which it had not before penetrated, or to instruct the persons lately received into the church, and to perform for them the various ordinances of Christianity. As parish churches arose, the necessity for such visits from the canons in the cathedral churches was diminished. But the institution remained: it was spared at the Reformation, and continues to the present day. These canons are sometimes called *prebendaries*. This arises from their being endowed with land or tithe, as many of them are to a greater or less extent, which endowment is called a *prebend*. The canons have stalls in the cathedral churches, which are generally called *prebendal stalls*. They form the chapter in the expression the dean and chapter, and are still nominally what they actually once were, the council of the bishop for the administration of the affairs of his diocese.

From *canon* is formed *canonical*, which occurs in many ecclesiastical terms, as *canonical hours*, *canonical sins*, *canonical punishment*, *canonical letters*, *canonical obedience*, and *canonical scriptures*. These terms require no explanation, except it be to add that the canonical scriptures are the usually received books of the Old and New Testament.

CANON (in mathematics). This word, which signifies a rule, has generally been employed to mean a set of mathematical tables. Thus it was customary to speak of the canon of logarithms, of sines, &c. A collection of formulæ has sometimes been called by the same name, and even any mathematical instrument. (*Vitalis, Lex Math.*)

CANON in music (*κανών*, a rule), a composition, generally vocal, sometimes in two, but commonly in more parts, in which, with the exceptions that will be mentioned, precisely the same melody, or subject, is given to every part. Thence the word, from the fact that every part follows the same *rule* or *model*. This melody is sung by each, after the leader, either on the unison, or the octave, or on the fourth and octave, &c., below, the voices severally following or answering each other at the expiration of one or more bars. According to many German and French writers the canon is a *perpetual fugue*, but this definition is liable to great objection: indeed, the term *fugue* is itself by no means satisfactory. [FUGUE.]

To compose a canon on the unison, or octave, requires less labour than genius, and, with very few exceptions, is the only composition of the kind that produces a constantly agreeable effect. A canon is said to be written *three-in-one* (or *four-in-one*, &c.) on the unison, when the parts follow on the same degree of the scale. Cherubini's 'Perfida Clori,' and Dr. Hayes's 'Come follow me to the greenwood tree,' are admirable examples of this sort. The renowned 'Non nobis, Domine,' of Birde is an unrivalled specimen of the canon three-in-one, on the fourth and octave below; and Dr. Blow's 'Gloria Patri' (engraved on his monument in Westminster Abbey), a canon four-in-one, on the fifth, octave, and twelfth below, is entitled to the encomiums that have been bestowed on it.

A canon in many parts may have two or even more melodies. Thus a canon four-in-two is for four voices, two singing one melody, two another, both subjects blending. But the canon takes numerous shapes, which it would be impossible, even if it were desirable to describe in this place. The *Canon by Augmentation* is that in which the notes of the answers are double and quadruple in length as compared with those of the subject. Dr. Cooke's 'Amen' (regularly sung after 'Non nobis' at the Catch-Club) is an ingenious example of this species. The *Canon by Diminution* is exactly the reverse of that by

augmentation. The canon *Recte et Retro* has but one peculiarity, and pretends to only one merit, namely, that it may be sung either forwards or backwards. And here we cannot forbear expressing a regret that any composer of real talent should have exposed himself to the mechanical drudgery of generating such ungrateful offspring as canons, except those in the unison. In schools, as exercises for youth, they may be of some use; but even there, if much importance should be attached to them, the imagination of the student will be in danger of being chilled, and his taste depraved. To reduce art to such rule as canon imposes, is preposterous, for it is impossible to name a single composition of the kind that might not have been improved by a breach of the laws laid down for its formation. Canons in music are what acrostics and *bouts-rimés* are in poetry. Good sense now disdains such laborious trifling in literature; let us hope that it will soon prove as influential in the sister-art.

CANON LAW (adopted from the Greek word *κανών*, signifying a rule,) a collection of ecclesiastical constitutions for the regulation of the polity and discipline of the Church of Rome, consisting for the most part of ordinances of oecumenical or general and provincial councils, decrees promulgated by the popes with the sanction of the cardinals, and decretal epistles and bulls of the popes. The origin of the canon law is said to be coeval with the establishment of Christianity under the apostles and their immediate successors, who are supposed to have framed certain rules or canons for the government of the church. These are called the apostolical canons; and they are said to have been drawn up by Clement, bishop of Rome, A.D. 93: they did not, however, appear till the 3rd century, and are now generally treated as the production of that age.

These rules were subsequently enlarged and explained by general councils of the church. The canons of the four councils of Nice, Constantinople, Ephesus, and Chalcedon (which were held at different times in the 4th and 5th centuries), received the sanction of the secular power by a law of the Emperor Justinian. (Novel. 131, cap. 1.) The chapter referred to, after confirming the decrees of the four councils, adds, "we receive the doctrines of the aforesaid holy synods (that is, councils) as the divine Scriptures, and their canons we observe as laws." Collections of these canons were made at an early period. The most remarkable of these collections, and that which seems to have been most generally received, is the *Codex Canonum* which was compiled by Dionysius Exiguus, a Roman monk, A.D. 520. This body of constitutions, together with the capitularies of Charlemagne and the decrees of the popes from Siricius (A.D. 398) to Anastasius IV. (A.D. 1154), formed the principal part of the canon law until the 12th century. The power of the popes was then rapidly advancing to the height which it afterwards attained, and their jurisdiction being constantly extended by new encroachments, required a uniform system of law for the regulation of their decisions.

This necessity excited the active zeal of the monkish lawyers. After some minor compilations had appeared, a collection of the decrees made by the popes and cardinals was begun by Ivo, bishop of Chartres, in 1114, and perfected by Gratian, a Benedictine monk, in the year 1150, who first reduced these ecclesiastical constitutions into method. The work of Gratian is in three books, arranged and digested into titles and chapters in imitation of the *Pandects* of Justinian, and is entitled '*Concordia discordantium Canonum*,' but it is commonly known by the name of '*Decretum Gratiani*.' It comprises a series of canons and other ecclesiastical constitutions from the time of Constantine the Great, at the beginning of the 4th, to that of Pope Alexander III., at the end of the 12th century. The *Decretals*, which were rescripts or letters of the popes in answer to questions of ecclesiastical matters submitted to them by private persons, and which had the authority of laws, were first published in 1234, in five books, by Raymond de Renafort, chaplain to Pope Gregory IX. This work, which consists almost entirely of rescripts issued by the later popes, especially Alexander III., Innocent III., Honorius III., and Gregory IX. himself, forms the most essential part of the canon law, the *Decretum* of Gratian being comparatively obsolete. These decretals comprise all the subjects which were in that age within the cognisance of the ecclesiastical courts, as the lives and conversation of the clergy, matrimony and divorces, inquisition of criminal matters, purgation, penance, excommunication, and the like. To these five books of Gregory, Boniface VIII. added a sixth (in 1298), called '*Sextus Decretalium*,' or the '*Sext*,' which is itself divided into five books, and forms a supplement to the first five books, of which it follows the arrangement. The *Sext* consists of decisions promulgated after the pontificate of Gregory IX. The *Clementines*, or *Constitutions* of Clement V., were published by him in the council of Vienna (in 1308), and were followed (in 1317) by those of his successor, John XXII., called '*Extravagantes Johannis*.' To these have since been added some decrees of later popes, arranged in five books after the manner of the '*Sext*,' and called '*Extravagantes Communes*.' All these together, namely, Gratian's *Decree*, the *Decretals* of Gregory IX., the *Sext*, the *Clementines*, and the *Extravagants* of John XXII. and his successors, form what is called the *Corpus Juris Canonici*, or body of canon law. Besides these the institutes of the canon law were compiled by one John Launcelot, by order of Paul IV., in the 16th century; but it appears from the author's preface, that they were never publicly acknowledged by the popes. And in 1661 was published a collection of the decretals of

ARTS AND SCI. DIV. VOL. II.

different councils, which is to be found in some editions of the *Corpus Juris Canonici*, but this likewise has never received the sanction of the Holy See. It is to be remarked that the canons of the Roman or Latin churches were never received by the Eastern or Greek Church.

The introduction of this new code into the European commonwealth gave rise to a new class of practitioners, commentators, and judges, almost as numerous as those who had devoted themselves to the study and exposition of the civil law, from which, as from an analogous system of jurisprudence, they looked for aid in all cases of difficulty and doubt. In fact, the two systems of law, though to a certain extent rivals, became so far mutually entwined, that the tribunals of the one were accustomed, wherever their own oracles were silent, to adopt the rules of decision that prevailed in those of the other; thus it became customary for those practising before those tribunals, to assume the degree of "*Doctor utriusque juris*."

The main object of the canon law was to establish, by means of the legislative authority of the pope, the supremacy of ecclesiastical authority over the temporal power, or at least to assert the total independence of the clergy upon the laity. The positions, that the laws of laymen cannot bind the church to its prejudice, that the constitutions of princes in relation to ecclesiastical matters are of no authority, that subjects owe no allegiance to an excommunicated lord, are among the most prominent doctrines of Gratian's *Decretum* and the decretals; but the constitutions of Clarendon, promulgated by Henry II., to curb the arrogance of 'A Becket, put an end in England to the claims of the clergy to exemption from secular jurisdiction. We have shown in a former article [BENEFICE] that the encroachments of the church upon temporal rights and authorities were never encouraged in England. The doctrines of passive obedience and non-resistance, so slavishly inculcated by the *Decretals*, were not likely to be relished by the rude and fierce barons who composed the parliaments of Henry II., Henry III., and Edward I. Accordingly we find that this system of jurisprudence never obtained a firm or extensive footing in this country: and our most eminent lawyers, in all periods of our history, have shown great unwillingness to defer to its authority. It is well observed by Blackstone ('*Com.*' i. p. 80), that "all the strength that either the papal or imperial laws have obtained in this realm is only because they have been admitted and received by immemorial usage and custom in some particular cases and some particular courts; and then they form a branch of the *leges non scriptæ*, or customary laws; or else, because they are in some other cases introduced by consent of parliament, and then they owe their validity to the *leges scriptæ*, or statute law." There was indeed a kind of national canon law, composed of *legatine* and *provincial* constitutions, adapted to the exigences of the English Church. Of these the former were ecclesiastical laws enacted in national synods held under the cardinals Otho and Othobon, legates from Pope Gregory IX. and Clement IV., in the reign of Henry III. The provincial constitutions were the decrees of provincial synods held under divers archbishops of Canterbury, from Stephen Langton, in the reign of Henry III., to Henry Chichele, in the reign of Henry V., and adopted also by the province of York in the reign of Henry VI. (Blackstone, '*Com.*' i. p. 83; Burn's '*Eccl. Law*,' preface.)

Previous to the Reformation, the metropolitan of each province had the power of making in convocation such canons as received its sanction; but when the king became the head of the church, it was enacted (25 Hen. VIII. c. 19), that no constitutions or ordinances, provincial or synodal, or any other canons, should be made or promulgated by the clergy without the king's assent and licence (this proviso stands unrepealed, it is therefore not competent to convocation to enact canons independent of the sovereign's permission). The same statute (repealed by 1 Philip & Mary, c. 8, but revived by 1 Eliz. c. 1) also provided that such canons, &c., as had theretofore been made by the clergy of the realm, should be reviewed by the king and certain commissioners to be appointed under the act, but that, till such review should be made, all canons, constitutions, ordinances, and synodals provincial, being then already made and not repugnant to the law of the land or the king's prerogative, should still be used and executed. No such review took place in Henry's time; but the project for the reformation of the canons was revived under Edward VI., and a new code of ecclesiastical law was drawn up under a commission appointed by the crown under the stat. 3 & 4 Edward VI. c. 11, and received the name of *Reformatio Legum Ecclesiasticarum*; but the confirmation of this was prevented by the premature death of the king.

In 1571, a Latin copy of the *Reformatio Legum Ecclesiasticarum* was produced in parliament as the model for a code of canon law. It was resolved that it should be translated into English, and referred to a conference of members of the house to be had with the bishops, for the purpose of reforming the ecclesiastical laws, and considering the articles of religion. Archbishop Parker, however, objected to it as omitting the Homilies, and containing no form for the consecration of bishops, and claimed for himself and the bishops, without the intervention of parliament, the sole right to judge of and determine the matter. Some warm discussion took place between him and one of the members of the conference (Wentworth), but the matter was allowed to drop, and the *Reformatio Legum Ecclesiasticarum* remains only as historically illustrating the principles which actuated the early reformers; but although of no legal authority it is, as observed by

P P

Lord Stowell, "a work of great authority in determining church matters, whatever be its correctness in matters of law." (Hutchins v. Denzcløe, 1 Haggard's Consis. Rep. 179.) In 1603, another effort, attended with more success, was made to draw up a form of canons.

James I. empowered by letters patent, directed to the Bishop of London (in consequence of the death of the Archbishop of Canterbury, and his successor not being then appointed), the Bishop and clergy of the province of Canterbury, to agree in convocation upon such canons, &c., as they should think "necessary, fit and convenient, for the honour and service of Almighty God, the good and quiet of the church, and the better government thereof." The result was the canons of 1603, to which the king gave his royal assent "according to the form of a certain statute made on that behalf in the 25th year of King Henry VIII., and by our said Royal and Supreme authority in causes ecclesiastical, to ratify by our letters patent under our Great Seal of England, and to confirm the same." These canons contain for the most part, save where modified or aided by statute, the ecclesiastical law of England; but not having received the sanction of parliament they do not bind the laity, but having received the sanction of the Sovereign, the clergy are amenable to them. (Lord Hardwicke in Middleton v. Croft, Strange's Rep. 1056). In 1640, the Archbishop of Canterbury (Laud) produced, to the convocation assembled in St. Paul's, a commission under the Great Seal to enable the two houses to agree upon the explanation or alteration of any canon then in force, or to make such new ones as should be thought convenient for the government of the church. A form of canons was accordingly drawn up and approved by the Privy Council and judges, and adopted by the province of York, but they have not been received as superseding or affecting the canons of 1603. It may be added that the canons of 1603 were framed in Latin, and that the English translation is in some parts not strictly accurate (for example, the 100th). It is somewhat difficult to state with accuracy in what the canon law of England is at this day comprised.

The statute of Henry VIII. admits those canons (albeit of the Romish church) which previous to the passing of that Act had been received and adopted either by the consent of parliament or from *immemorial usage and customs*. Ecclesiastical authorities have received our own domestic canons, chiefly to be found in Lepidwood's 'Provinciale,' and Gibson's 'Codex.' The canons of 1603 stand alone in weight and authority, but they affect the clergy alone. The injunctions of Edward VI. and Elizabeth, together with constitutions of Peckham and other archbishops, although of no great authority, still must not be omitted in a summary of our canon law.

There are two species of courts in England, in which the canon law is under certain restrictions used. 1. The courts of the archbishops and bishops and their derivative officers, usually called in our law courts Christian, *Curiæ Christianitatis*, or ecclesiastical courts. 2. The courts of the two universities. In the first of these, the reception of the canon law is grounded entirely upon custom; but the custom in the case of the universities derives additional support from the acts of parliament which confirm the charters of those bodies. They are all subject to the superintendence and control of the courts of common law, which assume the exclusive right of expounding all statutes relating to the ecclesiastical courts, and will prohibit them from going beyond the prescribed limits of their respective jurisdictions; and from all of them an appeal lies to the king in the last resort.

Before the Reformation, degrees were as frequent in the canon law as in the civil law. Many persons became graduates in both, or *juris utriusque doctores*; and this degree is still common in foreign universities. But Henry VIII., in the 27th year of his reign, issued a mandate to the university of Cambridge, to the effect that no lectures on canon law should be read, and no degrees whatever in that faculty conferred in the university for the future.* It is probable that Oxford received a similar prohibition about the same time, as degrees in canon law have ever since been discontinued in England.

Before we conclude this article, it may be as well to observe that the Decree of Gratian and the Decretals are usually cited not according to book and title, but by reference to the first word of the canon, which renders it necessary for the modern reader to consult the alphabetical list of the canons, in order to find out the book, title, and chapter, under which the canon he wishes to consult is to be found.

CANOPUS, the name of an Egyptian jar of a big-bellied form, with a cover or top representing a human head or that of some animal, and frequently having handles. These vessels are generally made of baked earth, sometimes of alabaster, and even of green basalt, and they are often represented on Egyptian coins: several of the so-called Alexandrine medals have canopi on the reverse. Some have hieroglyphics on them, and are painted and glazed; and they occur so fresh and new in appearance that Belzoni, when one was offered to him for the first time, thought the Arab was attempting to palm upon him a new jar for an ancient one. Bodies of sacred animals are sometimes found in these vessels; and they appear to have been much used in religious ceremonies. Canopus is the Greek form of the name of an Egyptian deity; but that the deity was the same as Cneph or Cneph, as some have asserted appears, to say the least, very doubtful. Earthen jars

* Stat. Acad. Cantab., p. 137.

of this form seem to have been used for keeping water cool, as they still are in Egypt. The British Museum contains several excellent specimens of these canopi. ('Egyptian Antiquities,' vol. ii.; 'Description de l'Égypte,' vol. i.; Jablonsky, 'Pantheon Ægypt.,' vol. iii.; Wilkinson, 'Ancient Egyptians,' vol. ii.)

CANOPUS, a star of the first magnitude, in the rudder of the constellation Argo. In Ptolemy it is *κάρωβος* (*canobus*), in Pliny, *canopus*. It does not become visible to any part of the earth higher in latitude than the southern part of the Mediterranean.

Hyginus, the author of a book of gossip about the stars, and Martianus Capella, a poet (cited by Grotius), have stated that Canopus was a star in the constellation Eridanus, which they say was the Nile, and the star was therefore the island of that name. Sir John Hill, a modern Hyginus, author of just such another work, has stated that "some old astronomers" have placed Canopus as above described; and Dr. Hutton, who should not have made an authority of Sir John Hill, has copied his words, and repeated the mistake in his 'Mathematical Dictionary.' It therefore becomes worth while to correct it.

CANOPI, the covering over a niche used in Gothic architecture. Being intended not merely as a covering to protect the statues under them from the weather, but as a mark of distinction also, they were used like a baldachin. Hence, as they afford an opportunity for the display of considerable taste and ingenuity, they are usually elaborately and often very beautifully carved. Canopies are sometimes met with in Norman tombs, &c.; they occur more frequently in first pointed architecture, but they are most freely used in the middle and third pointed or decorated and perpendicular styles of English Gothic. In French Gothic buildings canopies are found of exceeding richness. The various Gothic edifices, and especially the cathedrals, in England present numerous examples of canopies, and they occur frequently, and of the most elaborate kind, on the tombs of our kings and princes, placed horizontally, and therefore in such a situation as clearly shows that they were intended, like a baldachin, to be a mark of honour, and not a mere covering. [BALDACHIN.] The dripstone over a window or door is also called a canopy when enriched.

CANTA'TA, in music (from *cantare*, It. *to sing*), originally signified a short lyric drama, consisting of recitative, airs, duets, and occasionally choruses, the subject of which was sometimes sacred, sometimes pastoral, but more commonly of the erotic kind. The invention of the cantata is generally ascribed to Giacomo Carissimi, pontifical Maestro di Cappella, about the year 1650. The 'May Queen,' by Mr. Sterndale Bennett, is one of the most recent English examples of the cantata in this its complete form; and the 'May Day,' by Mr. Macfarren, is another. Subsequently the cantata assumed a more contracted form, and was written for a single voice. Of the latter kind, the most celebrated are those of Alessandro Scarlatti, Handel, Porpora, Marcello, Pergolesi, &c. Purcell's 'Mad Bess' and 'From Rosie Bowers' are cantatas that far exceed in depth of feeling and richness of harmony any that either preceded or followed them. Dr. Pepusch's 'Alexis,' a lighter composition, is a justly-admired cantata; and Dr. Arne's 'Cymon and Iphigenia,' for simplicity and sweetness of melody, is entitled to our notice.

CANTEEN, a small wooden vessel capable of containing three pints, which is carried by each soldier on the march on foreign service or in the field. The use of them has been some time general in the British army; they are usually made of oak and painted blue. They are slung over the shoulder by a leather strap, and have the number or appellation of the battalion and regiment, and the number or letter of the company to which they belong painted on one side.

Another kind of canteen is a square box fitted up with compartments, in which officers on foreign service pack a variety of articles, such as spirit-bottles, tea and sugar canisters, plates, dishes, knives, forks, glasses, and other requisites for the table.

A canteen is also a place in barracks where a licensed sutler is allowed to sell provisions, liquors, coffee, &c., to non-commissioned officers and privates, and the quarter-master of the regiment is responsible that no irregularity occurs; the sale of wine, beer, or spirits is not allowed except at the canteen, and the quantity sold at one time is regulated by the commanding officer.

CANTHARIDIN. Spanish flies contain a crystalline principle, discovered by Robiquet. In order to isolate it, the flies are to be digested in alcohol; the alcoholic solution is to be evaporated to dryness, and treated with ether, which dissolves the cantharidin, and by spontaneous evaporation deposits it in the state of micaceous particles, which are to be purified from some yellow matter by washing with alcohol.

The properties of cantharidin are—that when pure it is insoluble in water, but very soluble in boiling alcohol, and crystallises from it as the solution cools. It is also very soluble in oils, but neither acetic nor hydrochloric acid dissolves it; it melts when heated, and sublimes without decomposing at a high temperature. It is to this principle that cantharides owe their blistering power. One grain of cantharides, mixed with an ounce of lard, is sufficient to produce a very powerful blistering effect when applied to the skin.

According to Regnault, cantharidin consists of carbon 61.68, hydrogen 6.04, and oxygen 32.28, or $C^{61.68}H^{6.04}O^{32.28}$.

CANTHARIS OFFICINALIS (Geoffroy); *Meloe vesicatorius* (Linnaeus); *Lytta vesicatoria* (Fabr.); *Cantharis vesicatoria* (Latreille, and 'London Pharma.' 1851); is extensively employed to produce blisters.

The volatile principle which is exhaled by the living insect is so pungent as to cause great inconvenience to those who approach the trees where they alight. They are generally collected during the morning or evening when somewhat torpid, by persons, whose face and hands are protected by coverings, shaking or beating with poles the trees on which the insects are seated. The most common method of killing them is to expose them to the vapour of hot vinegar; they are then dried on hurdles, and put up for use. Turpentine is said to protect them from the attacks of certain small insects, which prey upon particular parts of the dead insects. These insects are, a mite (*Acarus domesticus*), a moth (*Tinea flavifrontella*), and two very small beetles (*Anthrenus muscorum* and *Hoplia farinosa*).

The common blistering fly is sometimes found in Suffolk and Essex. Though bearing the name of Spanish blistering flies, the greatest quantity is obtained from St. Petersburg; and the Russian insects are superior to those from Sicily or France. When good, they are of a shining yellowish-green colour; the odour is strong, virose, disagreeable, resembling that of mice; taste acrid, caustic, urinous. By drying they lose a great portion of their weight; but age does not greatly lessen their active properties if preserved from damp. The worms or insects which attack them feed only on the inert part, and are only so far injurious that they create a quantity of dust which is not vesicant; consequently, where worms are present in large proportion, more of the powder must be employed.

Cantharides, analysed by Robiquet, yielded:—

1. A green, fluid oil, insoluble in water, but soluble in alcohol (inert).

2. A black matter, soluble in water, but not in alcohol (inert).

3. A yellow viscid matter, soluble in water, and in alcohol at the common temperature; which has no vesicating power.

4. A white substance, under the form of small crystalline plates; when pure, insoluble in water; but soluble in that liquid when mixed with the yellow matter; soluble in boiling alcohol, from which it is deposited on cooling in crystalline plates; it is also soluble in fixed oils. To this principle the name of cantharadin has been given; many consider it a kind of animal camphor. It is the vesicating principle of the insect. [CANTHARIDIN.]

5. Another fatty matter, insoluble in alcohol (inert).

6. Phosphate of lime }
7. " magnesia } in the skeleton.

8. A small portion of free acetic acid.

9. A still larger portion of free uric acid.

Possibly other principles exist in them. The odour is due to a volatile oil, which is very pungent, and when it reaches the eyes causes severe ophthalmia.

Cantharidin may be extracted in various ways; but where it is desired for practical purposes to employ cantharidin apart from the other constituents of the fly, turpentine, at the temperature of 212° Fahr., allowed to stand upon a number of the powdered flies, especially the large female flies, will extract it; and the terebinthinate solution may be used as a most efficacious vesicant. Cantharidin is so powerful, that one-hundredth part of a grain applied to the skin will excite vesication. Cantharides are employed both externally and internally; but even when applied externally, should their active principles be absorbed, the same effect will be produced as if taken by the mouth. Applied to the skin, in moderate quantity, the only effect is rubefaction of the part, followed in general by vesicles or blisters, and the secondary effects of counter-irritants on the system at large. Should any of it be absorbed, a specific effect will be exerted on the urino-genital organs, precisely as if administered by the mouth. If a very large quantity be absorbed or introduced into the system by the mouth, or any other channel, such as injection by a vein, a powerful and often dangerous degree of action is exerted on the cerebro-spinal system, giving rise to violent nervous symptoms. The quantity which acts as a poisonous dose varies greatly in different individuals. This difference of degree of action is referable to idiosyncrasy; and while one individual has been sensibly affected by merely smelling the powder, six ounces of the tincture have been taken by another without injury. It is a medicine which requires the utmost circumspection in its administration. Even the process of powdering it should be carried on in such a way as to secure the operator from either inhaling any of the floating particles, or from receiving the volatile principle in his eyes. For internal administration, a solution in alcohol or ether is preferable to the powder, as it can be more perfectly incorporated with any fluid vehicle, and prevented from remaining in contact with the mouth or palate. The cases in which its internal exhibition is necessary or justifiable are very few. In some cases of atony of the bladder its use may be allowed; but it is productive of no benefit in diabetes, and should be avoided. Externally cantharides may be employed in various forms for different purposes, to act as a local stimulant, to cause rubefaction, to produce vesicles and a discharge of fluid, or simply for their secondary effects, which may be either stimulant or sedative, according to circumstances. As a local stimulant, tincture of cantharides is very useful in the languid circulation of the extremities which leads to the formation of chilblains. Cantharides appear to act primarily on the nerves of the part to which they are applied, and afterwards on the vessels. In certain conditions of the nervous system, such as occur in

apoplexy and palsy, they do not cause vesicles to arise. To produce a rubefacient action, either a mixture of the tincture with some oleaginous fluid may be applied, or the common blistering plaster may be laid upon the part, and both removed before vesication has occurred. This limited application of so potent an agent is often useful, and in some instances all that can with safety be employed. In the inflammatory complaints of young children or feeble persons, it is necessary to remove the applied substance before vesicles form, otherwise troublesome ulcers and occasionally gangrene ensue; this is particularly apt to follow when measles have preceded the application of a blister. Sometimes the discharge of the serum is as exhausting as blood-letting, and must be avoided by the above precaution. To quiet the irritability of the nervous system of old people, accompanied with restlessness, fidgettiness, and discontent, nothing is more effectual than this limited application of cantharides to the nape of the neck. In many chronic cutaneous diseases, especially of the squamous or scaly, and even of the pustular kind, the repeated application of blisters kept on only for a short period is very advantageous. Nothing will so soon cure (along with proper internal treatment, and attention to diet and regimen) ring-worm of the scalp, as blisters applied alternately with poultices, followed by creosote, so soon as the inflammatory stage is removed. As a general rule, blisters, or the employment of cantharides in any way, are not proper at the commencement of any inflammatory complaint. But after the stage of great vascular excitement is over, and when a failure of the vessels of the parts is likely to take place, blisters are of unquestionable service. Also when diseases are assuming the chronic form, blisters have great power in preventing this, or removing it when it has actually occurred. In deep-seated diseases of the joints or bones, the frequent repetition of small blisters in the neighbourhood of the part is of much utility. They are also of great use in relieving pain of the chest in the latter stages of phthisis pulmonalis.

In case of an over-dose, it is more easy to say what should not, than to say what should be done. If vomiting has begun, it should be encouraged, and should be caused where it has not commenced, in order to remove the substance from the stomach; but the stomach-pump is inadmissible, owing to the state of the throat and pharynx. Oily fluids are condemned by some, who affirm that even warm water is bad. Venesection may be necessary; but the state of the nervous system is to be kept in view, and the excitement, if any, moderated, or if there be lethargy, the person is to be roused. Camphor is of little use in allaying the strangury, hæmaturia, and other signs of over-action of the kidneys: opiate enemata are most useful against these symptoms.

Several other insects contain cantharidin, such as the *Meloe proscarabæus*, the *Mylabris cichorii*, the *Coccinella septempunctata*, &c. These or others are used in different parts of the world to produce vesications, especially the *Cantharis vitatta*, or potato-fly, and *C. atrata*, both in North America; *C. ruficeps*, in Sumatra and Java; *C. gigas* and *C. violacea*, in the East Indies; *C. atomaria*, in the Brazils; *C. Syriaca*, in Arabia; *Meloe majalis*, *M. proscarabæus*, and *Mylabris cichorii*, in China and East Indies, also *Mylabris trianthemæ*; *M. pustulata*, Cape of Good Hope, used in China; *Lydus trimaculatus*, in the north of Europe.

The old crude method of applying blistering plaster made of the powdered flies is almost entirely exploded. A small portion of linen cloth cut the size and shape of the blister desired is to be dipped in the acetous or terebinthinate solution of cantharides and applied to the spot. Or the portable and clean vesicating paper, or blistering tissue paper are preferable. Chloroform is a good solvent for cantharidin. Very improper uses are occasionally made of cantharides, from which serious injury may result. These are sometimes given or taken from ignorance, but more frequently with a criminal object. Cantharides is an ingredient in a preparation of iron or steel, where its presence is not suspected. Common iron or steel lozenges are safe enough where any preparation of iron is required, but the aromatic lozenges of steel contain, besides sulphate of iron, tincture of cantharides—the prolonged or injudicious use of which may have an injurious effect on the kidneys, bladder, &c., not to mention the nervous symptoms cantharides can produce. These nervous symptoms do not always appear immediately; sometimes not for a week or a fortnight, when their cause may not be remembered or suspected.

CANTICLES. [SOLOMON, THE SONG OF.]

CANTILEVER, a bracket with a projection beyond the line of the supporting wall, considerably in excess of the width of its face. The name is applied utterly irrespective of the nature of the material of which the cantilever is composed. The strength of a cantilever is to be ascertained by considering it as a beam loaded at one end, and having one solid bearing, unless the section should be such as to render it equivalent to a beam supported also by an inclined strut.

CANTO FERMO. [PLAIN CHANT.]

CANTON'S PHOSPHORUS. [CALCIUM, SULPHIDE OF.]

CANTONMENTS are the dwelling-places occupied by an army during any suspension of active operations in the field [TACTICS]: the term, though frequently applied to winter-quarters, particularly designates the more temporary shelter which an army may occasionally take; for example, during a season of excessive heat. The troops are distributed in villages, houses, &c., as when in winter-quarters, but they are made to occupy a smaller extent of country, and hold themselves in readiness to take the field at a moment's warning.

CANVAS, is a plain, woven material, usually made of hemp, sometimes of flax, sometimes of a mixture of both, and occasionally of less-known fibrous substances. It is a coarse and strong fabric, used for sails, sacks, floor-cloth, tents, &c. All that need be stated concerning its manufacture will be found under FLOOR-CLOTH; SAIL-MAKING; WEAVING.

CANZONET', in music (*canzonetta*, Italian, a diminutive of *canzone*, or *canzona*, a song), a short song, one that is brief compared with the sacred airs of the oratorio, or with the *arie* of the Italian opera. Formerly the term was applied to vocal music in parts; now it is confined to songs for a single voice.

CAOUTCHEN. [CAOUTCHOUC.]

CAOUTCHIN. [CAOUTCHOUC.]

CAOUTCHOUC (India-rubber, Gum-elastic) is the dried milky sap of various plants. [INDIA-RUBBER, in NAT. HIST. DIV.] The fresh juice of the India-rubber tree in appearance closely resembles cow's milk; its taste is also somewhat similar, and it may be drunk without producing any marked injurious effect. It has an acid reaction. Allowed to stand for some time, it separates into two portions. Exposed under the microscope, it is seen to consist of a number of small globules, floating in a clear aqueous fluid; the globules are the caoutchouc, and form thirty to forty per cent. of the fresh juice.

Caoutchouc may be obtained in a pure state by frequently washing the sap with water, or by dissolving the common gum in chloroform, precipitating with alcohol, and drying at a temperature of 70° or 80°. It then has the appearance of gum arabic. Its ultimate principles are carbon and hydrogen, in the proportion of 87.2 of the former to 12.8 of the latter ($=C_8H_8$).

Caoutchouc has been known in Europe but little more than a century. As it occurs in commerce it is of a brownish colour, and has neither taste nor odour. Specific gravity .920 to .960. It is unaltered by exposure to the air; is soft, flexible, and very elastic. It burns readily, giving off much smoke. According to M. Payen, it is mainly composed of two proximate principles. One, forming thirty to forty per cent., perfectly taken up when caoutchouc is digested in solvents; the other, fifty to sixty per cent., only slightly soluble, but becoming very much swollen under their influence, owing to the penetration of the solution into the numerous pores which, under the microscope, are seen to traverse caoutchouc in every direction. By carefully renewing the solvent several times, these two principles may be separated from each other; in its highly extended state, however, the slightest agitation breaks up the insoluble one. It is in this way that ether, benzole [MARINE GLUE], bisulphide of carbon, oil of turpentine, and other essential oils, act upon caoutchouc. This porosity also explains the cause of the increase in volume and weight that caoutchouc undergoes when immersed in water, alcohol, and other liquids that exert no chemical action whatever upon it. The soluble principle is softer, less coloured, and much more adhesive than the insoluble portion, the latter however is much superior in tenacity and elasticity. The best solvent for caoutchouc is a mixture of six or eight parts of absolute alcohol with one hundred parts of bisulphide of carbon. Concentrated sulphuric or nitric acids slowly attack and decompose caoutchouc; beyond this it is unaffected by acids, alkalies, chlorine, or chemical agents generally; properties which render it almost invaluable for many purposes in the arts.

When caoutchouc is heated it soon softens, and at about 250° melts into a liquid having the consistence of tar. It does not solidify on cooling, but remains fluid for many months. In this state it forms an excellent lute for pneumatic apparatus; spread over a cork or stopper, it effectually prevents the escape of gases or liquids. Heated to near 600° caoutchouc boils, the greater part being converted into vapour, which by proper refrigerating apparatus may be condensed into a liquid having powerful solvent properties. By repeated rectification it may be obtained colourless. It rapidly dissolves, without the aid of heat, caoutchouc, copal, and the varnish resins generally. The boiling point of this liquid varies extremely. By the aid of freezing mixtures, a portion may be obtained which boils at about the freezing point of water. Specific gravity at 25° is .630. A large quantity distils over between 280° and 390°, and this, by repeated fractionation and purification, assumes a tolerably constant boiling point of 340°. Amongst these liquids *tetrylen*, *caoutchen*, and *eupion* seem to be present.

Caoutchin ($C_{20}H_8$) is the name given to the substance just mentioned. Its specific gravity is .842. Vapour density 4.461.

It is almost insoluble in water, and miscible in all proportions with alcohol, ether, and the fixed and essential oils. It combines with hydrochloric and hydrobromic acids, and is resinified by peroxide of hydrogen.

When a strip of caoutchouc stretched to five times its length is heated to 212° and allowed to cool slowly, it does not again contract. Advantage is taken of this fact in the manufacture of elastic cloth. A strip a foot long will thus by six successive operations yield a thread 15,625 feet in length.

Vulcanised India-rubber is obtained by causing sulphur to combine with caoutchouc. This may be done by triturating the latter, softened by digestion in naphtha, with ten to twenty per cent. of sulphur, and heating the mixture to 320°. Another method is by immersing sheets of caoutchouc for two or three hours in melted sulphur at a temperature of 240°, and then heating to 320°, when the vulcanisation imme-

diately takes place. A third process, accomplished without the aid of heat, consists in dipping the caoutchouc into bisulphide of carbon containing two and a half per cent. of protochloride of sulphur; after remaining in the solution for two or three minutes, it must be taken out and washed with water to remove excess of the chloride. By these processes the caoutchouc takes up from ten to fifteen per cent. of sulphur, one to two parts being chemically combined with it and the remainder absorbed by its pores. The latter may be removed by caustic alkaline solutions, bisulphide of carbon and other sulphur solvents. It is also gradually eliminated by the continued expansion and contraction which this kind of caoutchouc undergoes in several of its mechanical applications. Another process of vulcanisation, by which the excess of sulphur taken up by the pores is avoided, consists in heating the articles, manufactured of ordinary caoutchouc, for two or three hours in a solution of protosulphide of potassium contained in close vessels at a temperature of 284°. After washing first in alkaline solution and then in water, the objects are found to be very equally and thoroughly sulphurised.

Vulcanised caoutchouc is quite as elastic as the normal substance. Its great advantages over the latter are that it retains its elasticity when subjected to temperatures below the freezing point, and even above the boiling point of water: conditions under which unvulcanised caoutchouc would become in the one case quite hard, in the other soft and adhesive.

CAOUTCHOUC MANUFACTURES. The name *India-rubber* is extensively applied to this substance, and might have been adopted in the present case; but already many of the manufacturers are shortening it into the form of *rubber*; and, for aught we can tell, further changes of designation may take place. We shall therefore adhere to the original name.

Few departments of manufactures have owed more to the ingenious contrivances of one man than that of caoutchouc owes to Mr. Thomas Hancock, who took out his first patent nearly thirty years ago, and has secured more than a dozen patents in all. His name must necessarily be mentioned frequently in any fair account of the progress of this branch of industry, even if he had not been the author of the best extant work on the subject. It will be convenient—referring to the NATURAL HISTORY DIVISION for an account of the growth and early history of this remarkable substance—to commence with the year 1819, and rapidly glance at the chief inventions down to the present time.

1819.—Caoutchouc received its name of India-rubber from its remarkable property of rubbing out pencil-marks; but its elasticity and its imperviousness to moisture were known to the natives of the countries where the tree grows; and it was natural to expect that European and American manufacturers would endeavour to apply the substance in such a way as to render these properties available. Mr. T. Hancock commenced his experiments with the substance in 1819. He felt that one of the important questions to be determined was, whether caoutchouc can be dissolved so as to render it useful in that state. He first began with oil of turpentine, a liquid which is now known to be suitable to the purpose; but his early attempts were unsuccessful.

1820.—Laying aside the solvent operation for a time, Mr. Hancock applied his ingenuity to various modes of cutting the caoutchouc (imported in bottle-shaped masses) into thin pieces, and applying them as elastic additions to various articles of dress. He took out his first patent in 1820, for a method of applying these elastic pieces to glove-wrists, waistcoat-backs, waist-belts, pockets, braces, trouser-straps, gaiter-straps, stockings, garters, riding-belts, stays, boots, shoes, patens, and clogs. In the articles first manufactured under this patent, the elastic pieces were fastened to the garments by sewing; but the stitches broke away, and the holding was not secure. He therefore made the pieces additionally thick at the edges, and steeped them in hot water, to enable them to resist better the tearing action of the stitches. One of his contrivances was to cut the bottles of caoutchouc into rings, and apply these rings to the tops of gloves and stockings. Another was a mode of joining surfaces by pressure of the caoutchouc under hot water. A third was that of cutting the material into thin slices by a sharp-edged cutter working under cold water. By degrees there accumulated around him a large quantity of fragments of caoutchouc, which he endeavoured to bring into some use; he invented a *masticator*, consisting of a spiked roller working inside a spiked hollow cylinder; the tearing action of this machine, when the roller was made to rotate, gradually made the fragments hot, and combined them all into one mass. This advance was a very important one; the process was not patented, but Mr. Hancock contrived to keep the secret to himself and his workmen during the long period of twelve years: surreptitious imitators were thrown off the right scent by the process being called "pickling."

1821.—The masticating process was exposed to this difficulty: the gum resisted with immense force the tearing action, inasmuch that only two ounces at a time could be masticated by the wooden machine first made; but in 1821 an iron machine was made, worked by horse power instead of by a winch, and with it 15 lbs. could be treated at once. It was found, also, that if the caoutchouc were first heated to about 300°, the mastication was more readily performed.

1822.—Improved forms of machine, and improved modes of heating the caoutchouc, enabled the manufacturer to work up a larger and

larger quantity of fragments at once, and to produce a more homogeneous substance. The heating was now effected in metal vessels, surrounded by high-pressure steam. The caoutchouc was made into blocks, which were cut into thin slices by an ingenious but simple apparatus. It was now found that these sheets were soluble in good oil of turpentine, producing a thick liquid, which promised to be of great value in the arts.

1823.—Mr. Hancock procured a patent, in 1823, for a mode of combining caoutchouc with pitch, tar, and other substances, either in the mastication or by means of the solution. The compound was spread out by means of a hot iron protected by a damp cloth, and the sheets thus produced were used as an under-sheathing for ships beneath the copper. This manufacture was taken up by other firms, and many improvements made.

1824.—The easy production of a solution of caoutchouc soon led to important extensions. It was now found that the elastic pieces could be fastened to gloves, &c., by cementing with this solution instead of by sewing. The upper and under-leathers of boots and shoes were rendered waterproof by cementing in this way thin sheets of caoutchouc. Further applications of the caoutchouc, now rendered practicable, were to the edges of 'noiseless' wheels, the surfaces of rollers and cylinders, the cushions of billiard-tables, tubes and pipes, catheters and bougies, gas-bags, experimental balloons, and washers or collars for stop-cocks. Mr. Hancock obtained from America a small quantity of caoutchouc in its liquid or creamy state, and he took out a patent in 1824, for making a kind of artificial leather by its aid; he mixed the cream with felt, carded cotton, hair, hemp, or flax, dried and pressed it, and produced strong and tough sheets of a substance suitable for boot-soles, hose or water-pipes, straps for machines, harness, and other purposes, all waterproof, and free from stickiness of surface. In this year the name of Macintosh came into the trade. Mr. Charles Macintosh, of Glasgow, took out a patent for the double waterproof cloth, which has had such a world-wide reputation. Two layers of cotton or other cloth were cemented together with a solution of caoutchouc, and then pressed so closely and evenly as to preclude the passage of air or water.

1825.—The two inventors, Hancock and Macintosh, entered into a working agreement in 1825, concerning their respective patents. Macintosh made his own particular solutions at Glasgow; Hancock, his in London; a new factory was built at Manchester for the manufacture of waterproof cloth, while Hancock carried on other departments in the metropolis. Captain (afterwards Sir John) Franklin had several boat-coverings, four life preservers, eighteen bags for cork beds, and four pillows, made of Macintosh's waterproof cloth, for one of his Arctic expeditions; and the great service rendered by these articles tended to increase the reputation of the new material. In this year Mr. Hancock obtained another patent for making artificial leather, by using the caoutchouc solution instead of the native cream or sap. He procured flat fleeces of carded cotton wool, and pressed each fleece between two layers of cloth moistened with solution; by varying the process he could produce sheets of any thickness, and any degree of toughness; and they could have other qualities imparted to them by mixing the solution with resin, size, glue, ochre, pumice, or whiting. These sheets of so-called artificial leather came much into use for the backs of cards for carding-cotton, for blankets in calico-printing, for deckel straps in paper-making, and for machine-straps. The double textures, made of two different kinds by Macintosh and Hancock, became extensively manufactured into air-beds, bolsters, pillows, cushions, mattresses, swimming belts, life preservers, and surgical bandages; the outer surfaces were of jean, jeanet, cambric, silk, kid, or morocco; and the hollow spaces within were inflated by means of bellows acting through a valve or stop-cock. Another patent was taken out this year for a mode of applying the caoutchouc solution to ropes and cordage.

1826.—As it was found that tailors either could not or would not make up garments in a proper way from the waterproof cloth, Macintosh and Hancock were driven to take up this department themselves, and to establish shops for the sale of the garments; from this time the use of such garments by travellers and sea-faring men spread very rapidly.

1827.—Many manufacturers had by this time entered the trade, some of them devoting their ingenuity to articles which had not been attempted by Macintosh and Hancock. India-rubber shoes afforded a special example of this kind.

1828.—Hancock next established a working arrangement with a firm at Paris, sending over solution, sheets, workmen, and machinery, and leaving the Parisians to manufacture such articles as seemed most likely to find a market.

1830.—In 1830 Hancock sent an agent out to Para in Brazil, to instruct the natives in the best mode of collecting and shipping the gum in a liquid state; he still hoped to make some useful discoveries and inventions in this direction; but he ultimately found that the solution, as prepared by himself, was more commercially useful than the original sap.

1831.—About this time, the elastic properties of caoutchouc became more than ever valued, by the production of woven goods having caoutchouc either in the warp or weft. For such purposes a compound thread was formed, having a centre or core of caoutchouc, with an

envelope of cotton or worsted twisted round it. The method is said to have been first practised at Vienna, from whence it extended to Paris, and thence to this country. The bottle-shaped masses of caoutchouc were, in the first instance, cut up into slips. This used in the first instance to be done by cutting up the bottle with scissors, and then separating the layers of which it is formed; another plan was to soften the bottle, inflate it by a forcing-pump to the requisite degree of thinness, and then cut it; but the method finally employed was to soften the bottle in hot water, cut it into two halves, press it between two iron plates till it assumed a flat form, and cut the discs or pieces thus produced into ribbons, by a cutter working spirally from the circumference of the disc towards the centre. The ribbons so prepared were next cut into filaments or threads of the desired width, by passing them through a machine having a number of cutting edges. The threads were softened in warm water, and stretched by a winding machine to many times their original length; and being kept in that tended state till cool, they did not spring back again when released. They were then attached to a braiding-machine, and sheathed with threads of cotton, silk, linen, or other material. The threads so sheathed were used as 'warp' or long threads, and were woven into the kind of textile fabric required. A heated iron passed over the woven goods caused the caoutchouc to relax, corrugated the sheathing, and gave to the whole a great elasticity and power of yielding without fracture. If the caoutchouc thread were sheathed while in the natural state, it could not afterwards be stretched without breaking the sheathing; and it was for this reason that the sheathing was applied to a stretched thread of the inner material. Sometimes the compound threads sheathed in this way were used as alternate warps only, sometimes both for warp and weft; and various other modifications were adopted according to the purpose to which the woven material was to be applied. Gloves began very soon to be made at Leicester and Nottingham with caoutchouc knitted into the wrist; and stockings with the same material at the top, to serve in lieu of garters.

1833.—By the year 1833 civil engineers and manufacturers had become accustomed to the use of a large number of articles made of caoutchouc, including gas-bags for repairing main-pipes, pump buckets, plug-ball valves, hydraulic ram packing, buffer-rings, cylinders of tubes of various diameters, hose-pipes, machine-bands, fire-engine hose, malt-ing shoes ("anti-grain crushers"), gig spring blocks, &c.

1835.—Steam machinery became now necessary for working up the vast quantity of caoutchouc used at the Manchester factories; and many London firms also carried on the manufacture on a considerable scale. Another patent was obtained by Hancock for improving his air-beds and cushions; by corrugating the outer casing of cotton or canvas, the cushions were rendered more soft, yielding, and elastic. A year or two afterwards he obtained another patent for applying the caoutchouc to cloth in a dough-like state instead of a solution, producing results more useful for certain purposes. And another, by the same indefatigable inventor, bore relation to the production of wide sheets of any length and width; cloth was used, but only to spread the caoutchouc upon, and was susceptible of separation by a preliminary preparation in a particular way.

1840.—By this year the Manchester factory of Messrs. Macintosh and Co., often produced four thousand square yards of waterproof cloth per day, so large was the demand for the various purposes above indicated. Large air-proof vessels, like flat-bottomed boats, were made as substitutes for metal pontoons in military operations. Numerous other uses rendered necessary the means of masticating the caoutchouc more rapidly than ever; and a new masticator was made capable of treating 200 lbs. at once. This quantity was cast into a smooth, solid, homogeneous block, six feet long by one foot wide, and seven inches deep, ready to be cut and shaped into any desired forms.

1841.—About this time Mr. Brockedon devised an ingenious mode of making a substitute for corks, more equable than corks are usually found to be. In the first place, fibres of wool were felted or worked into an oblong rod or solid cylinder; this rod was cut up into pieces the proper lengths for corks, and the corks so made were coated with a thin sheeting of caoutchouc.

1842.—In this year a remarkable and important improvement was made by the admixture of sulphur with caoutchouc. Manufacturers had been much perplexed by three defects in the ordinary gum,—its clammy adhesiveness, its liability to be affected by change of temperature, and its sensitiveness to the effects of oil and grease. Of these, the second is the worst; the substance becoming hardened by cold and relaxed by heat. In 1842, an agent from Mr. Goodyear, an American inventor, brought to England a few specimens of caoutchouc which had been so treated as to lose these defects; he wished to negotiate for the sale of his invention; but as the process was kept secret, English manufacturers declined to treat. Mr. Hancock deemed it quite fair, commercially and morally, to try to discover by his own experiments how such an effect could be produced. After much time and trouble, he devised a mode of combining sulphur with caoutchouc, producing a compound possessing very curious and important properties. Mr. Brockedon suggested the name 'vulcanisation' for this process, and hence originated *Vulcanised India Rubber*. Mr. Hancock obtained a patent for this in 1843; and an English patent was also granted to Mr. Goodyear in 1844. The two patents were worked without interruption for eleven years; but in 1855, an action was

tried to determine whether Hancock had stolen Goodyear's idea. Hancock admitted that the specimens sent by Goodyear had suggested to him the expediency of a course of experiments; but contended that the experiments were entirely his own, unaided by any analysis of those specimens; and the decision was given in his favour—confirming the validity of both patents. Many other law-suits have taken place between rival patentees, in relation to this manufacture.

1845.—A patent was granted in this year for a mode of getting rid of the excess of sulphur in vulcanised caoutchouc, by a mode of treating it with a strong hot solution of sulphate of soda or potash; restoring to it the colour and transparency of the original material, without lessening those peculiar properties which the sulphur produces. Blocks and sheets of this extremely tough material began soon to be made for a very varied range of purposes. Twelve-inch cubes were made solid and uniform throughout; and sheets were formed a hundred and fifty feet long by nearly five in width. Mr. Cow, connected with one of the royal dockyards, suggested a very useful application of vulcanised sheets. Whenever a ship requires repair, it generally calls for the troublesome process of dry-docking, to examine the injuries without interference from the water; this dry-docking it was now found might in many such cases be dispensed with, by the use of a ship-sheet, a piece of vulcanised caoutchouc about ten feet square by three-eighths of an inch thick; this was lowered over the side of the vessel, and when properly adjusted, was pressed against the damaged part of the hull so firmly by the action of the sea or river water, as to permit the water within the ship to be pumped out, and the damaged place examined.

1846.—By this time, many articles previously made of plain caoutchouc were found to be better if made of the vulcanised material; while new applications were every week devised. The public thus became accustomed to the use of vulcanised caoutchouc for elastic bands, washers and packing for machinery, engine-valves, corrugated sheets for railway purposes, billiard cushions, hose-piping, tubing, surgical bottles, gig- and carriage-springs, hydrostatic bed-covers, sacking for iron bedsteads, solid wheel-tires, buffer-springs, japanned artificial leather, pump buckets, gas holders, buoys, vulcanised thread, trousers- and vest-straps, swimming belts, socket joints, printers' rollers, boots, overshoes, machinery bands, spherical valves, knee-caps, sheet expanders, baby jumpers, corn protectors, cigar cases and tubes, tobacco pouches, sponge and soap bags, jar covers, conical stoppers, bows for archery, playing balls, horse-shoes, greyhound and sheep stockings, cricket gloves and leggings, waggon and cart covers, rick covers, carriage aprons, knapsacks, canteens and drinking cups, &c. So tough is this material, that Mr. Hancock and Mr. Nasmyth, judging from certain remarkable experiments made by them at Patricroft, believed it might be usefully applied to the hulls of ships to render them shot-proof—a supposition not, so far as we are aware, yet practically tested. Two patents about this time gave a still greater extension to the use of caoutchouc: one was to render it softer than usual, so as to serve as a kind of spongy stuffing; the other was to render it harder than usual, by casting or pressing it upon moulds, and vulcanising it while in that state. The spongy caoutchouc did not find a very wide sphere of usefulness; but the other novelty admitted of very beautiful results in reproductions of chasing, carving, engraving, bas-reliefs, medallions, &c.; and also a very hard material for slabs, bars, tablets, inlaying, door-knobs, combs, knife-handles, carriage panels, and even flutes. Different degrees of elasticity, flexibility, toughness, hardness, and strength could thus be ensured, according as the caoutchouc was vulcanised before or after its fabrication into articles. The harder kind can be turned in a lathe, or have a screw-worm cut in it, as readily as wood; it is indeed strong enough to build houses, ships, and waggons of, if we had any motive to incur the expense.

1851.—By the year of the Great Exhibition, the caoutchouc manufacture had reached a high degree of excellence in England and America. No less than fifty English patents had been procured for the application of vulcanised caoutchouc to various purposes,—the vulcanising itself still being done by or under licence from the firm of Hancock and Macintosh. The Exhibition displayed in a striking way the ingenuity of the Americans in the use of caoutchouc. Many English productions had been prepared under a process patented by Mr. Parkes; he devised a mode of vulcanising thin sheets of caoutchouc very quickly, without the aid of heat, by treating them with a solution of chloride of sulphur in bisulphuret of carbon. Another patent, by Mr. Brockedon and Mr. Hancock, for a mode of combining caoutchouc with gutta-percha, led to the production of many very beautiful articles, thin sheets of this compound material being afterwards vulcanised by Parkes's process. Various inventors had devised modes of producing in caoutchouc some such change as vulcanisation by substances other than sulphur; and thus new useful forms of the gum came into notice, under the names of "galvanised," "mineralised," "metallised," and "thionised" caoutchouc.

1858.—The seven years following the Great Exhibition were marked by a development of all the various modes of employing caoutchouc, and by the invention of many new ones. The patents obtained were not so much for new processes, as for improvements on processes already known. One was for a mode of printing on surfaces of vulcanised caoutchouc, susceptible of subsequent expansion or contraction. Another was for a mode of using up scraps of vulcanised

caoutchouc—much more difficult to effect than when the gum is in the unvulcanised state. A third was for a new method of making vulcanised caoutchouc thread; and there were numerous others, which need not be particularised here. Messrs. Silver, at their works at North Woolwich, are endeavouring to render caoutchouc a substitute for gutta-percha as an insulating covering for telegraph wires.

The importation of caoutchouc, as may be supposed from the above details, has rapidly and largely increased. In 1850 it amounted to 800,000 lbs., whereas in recent years it has more than once exceeded 3,000,000 lbs. The produce of Brazil brought to market far exceeds that of all other countries combined. Singapore is the market to which the caoutchouc from Java, Sumatra, Malacca, Borneo, Penang, Manilla, &c., is brought, and from which it is shipped to England. Much of the caoutchouc brought into the market is found to be adulterated with chalk, Paris white, pumice, clay, barytes, oxide of zinc, white lead, red lead, ivory black, lamp black, black lead, and other substances.

CAPACITY, the same in sense as CONTENT of volume in pure mathematics. In physics it generally signifies power of holding or retaining. Thus we speak of the capacity of a body for heat, &c.

CAPELLA, or α Aurigæ, a star of the first magnitude, in the body of the goat which Auriga is represented as carrying. [AURIGA.] This is a double star, with a small proper motion, + 0".13 in right ascension, — 0".35 in declination.

CAPERS, considered botanically, are the flower-buds of the *Caparis spinosa*, a plant which grows largely upon rocks and ruined walls in the south of France and Italy, and which looks very attractive with its white blossoms and lilac stems. The flower-buds are picked as an article of commerce, to undergo a certain preparation before using. On an average, each plant yields about a pound of buds. The smallest quantity is yielded when picked young; but these are the finest, and bring the highest price. When the buds are picked, they are thrown into a cask of strong vinegar, and sold to dealers, who, by the use of various kinds of sieves, separate the buds into *nonpareils*, *capuchins*, *capotes*, *seconds*, and *thirds*, differing in quality and in price. The green colour of capers is an evil rather than a good; it does not naturally belong to them in the pickled state, but is produced by an artificial application of copper, which is in its nature deleterious. Capers, though not largely consumed in England, find a considerable sale in the south of Europe.

CAPIAS. This term denotes in law certain writs so called from the occurrence of the word (*capias*) in the ancient Latin forms:—

1. *Capias ad respondendum*. This is a judicial writ by which all personal actions (that is, such as do not relate to land or real property) were, prior to the 1 & 2 Vict. c. 110, commenced in the superior courts of common law against any person whom it was intended to arrest or hold to bail, and who was not already in custody.

Since the passing of that Act, the writ of *capias ad respondendum* is no longer the commencement of the action; and its use is restricted to certain special cases specified in the 3rd section, and noticed above. [BAIL.] In form it is a command from the king to the sheriff, to take the defendant if he shall be found in his bailiwick, and him safely keep until he shall have given bail, or made a deposit according to law in a specified action at the suit of the plaintiff, or until the defendant shall by other lawful means be discharged from custody. The sheriff is also required to deliver a copy of the writ on execution to the defendant; and the defendant is enjoined to take notice that within eight days after the execution of it he must cause special bail to be put in for him in the court from which the writ is issued. The sheriff is also commanded to make his return to the writ immediately after he has executed it, stating the day of such execution; or if not executed within one calendar month from the date, then that he also return it, or sooner, if lawfully required to do so. It is witnessed in the name of the chief judge of the court from which it issues, and is dated on the day it issues.

2. *Capias ad satisfaciendum*, usually called a *ca sa*. This is a writ of execution to imprison the person of the defendant after judgment has been obtained against him, until he make satisfaction to his creditor. It commands the sheriff (of any county within which the defendant is supposed to be) to take the defendant, and him safely keep, so that he may have his body in court on the return of the writ to satisfy the plaintiff. This writ must strictly pursue the judgment upon which it is founded; that is, in a judgment against two persons, the *ca sa* cannot issue against one only, without showing upon the face of it a valid reason for it being so; nor can it be sued out for a larger sum than has been recovered against the defendant.

Formerly it was the practice to *teste* (that is, date it) in Term time, but now it may be *tested* on the day on which it is issued (3 & 4 Will. IV. c. 67, s. 2). It may also by that act be made returnable immediately after the execution, instead of waiting until the ensuing Term, which was often productive of great loss and delay; nor is it now necessary that any certain number of days should elapse between the *teste* and the return. Where the sheriff can do so, he ought regularly to return, by indorsement on the back of the writ, the manner in which he has executed it; for instance, that he has either taken the defendant and has his body ready, or that the defendant is so ill that he cannot be moved, or that he is not to be found in his bailiwick. The writ, when returned, is lodged with a master of the court out of which it issued;

and a sheriff is answerable in damages to the plaintiff for making a false return.

Every writ of *ca sa* should be indorsed with the party's addition and residence, or such other description as the plaintiff may be enabled to give, together with the amount of the debt which the sheriff is to levy; the plaintiff at his peril indorses more.

The mode of executing this writ is generally the same as in the case of a writ of *capias ad respondendum*. Persons privileged from arrest under the one are generally so under the other. These privileges are noted above. [BAIL.]

The effect of taking a party in execution upon a *ca sa* is, that it operates at once as a satisfaction of the debt, and no other writ of execution can be sued out upon the same judgment against the defendant's goods or lands, unless he die in confinement or escape from custody.

3. *Capias ad satisfaciendum to fix the bail*. Where bail have been given in the original action, they stipulate in this triple alternative, that the defendant shall, if condemned in the suit, satisfy the plaintiff his debt and costs; or that he shall surrender himself a prisoner, or that they will surrender him, or pay the debt and costs for him. [BAIL.] Where therefore the defendant is at large after the judgment, and the bail are responsible, it is often of importance to fix them with the debt; for this purpose a *ca sa* must first be sued out against the principal, upon which the sheriff must return that he is not to be found, for the bail are not bound to render their principal until they know by the plaintiff's suing out this writ, that he means to proceed against the person of the defendant and not against his goods [EXECUTION]; and for the purpose of affording the bail this information, the writ must lie in the sheriff's office four clear days before the return, and be entered in a book kept for that purpose. It must be directed to the sheriff of the county where the action was tried. The sheriff returns that the defendant is not to be found as a matter of course, without even attempting to take him (except where he is actually in his custody) as the *ca sa* is merely intended as a notice to the bail of the plaintiff's intention to proceed against them; and if they do not render their principal in time, the plaintiff may proceed for the debt against the bail.

4. *Capias utlagatum* is a writ that lies against a person who has been outlawed in any action. It is either general or special; the former against the person only, the latter against the person, lands, and goods. (Stat. 2 Will. IV., c. 39, s. 5; and 7 Will. IV. and 1 Vict. c. 45, s. 2.) [OUTLAWRY.]

5. *Capias pro fine*, the name of an ancient writ now obsolete, by which the defendant who had judgment given against him might in some cases be arrested for his wilful delay of justice until he paid a fine to the king for the same.

6. *Capias in withernam* was a writ, now obsolete, which lay where a distress taken was driven out of the county, so that the sheriff of that county could not deliver them to the party applying to have them replevied. [DISTRESS, REPLEVIN.]

(Archbold's Practice, by Prentice, 10th edit.; Index, tit. Capias.)

CAPILLARY ATTRACTION and REPULSION. These names have been given to the properties of matter which cause the ascent or descent above or below the level of the surrounding liquid, which takes place when a tube of very small diameter (like a hair, *capillus*) is dipped into water, mercury, &c. This phenomenon, which excited early notice from its peculiarity and apparent exception to all the laws which regulate the equilibrium of fluids, has given its name to what is rapidly becoming an extensive and well connected theory of the action of the parts of solids and liquids upon each other. We shall, however, in this article confine ourselves to the description of phenomena which are strictly capillary, in the original sense of the word, referring to MOLECULAR ATTRACTION for an account of the general theory which explains these phenomena as particular cases of a more extensive class.

That solid substances, either directly or by means of some interposed agent, attract each other [ATTRACTION, where this article is referred to as CAPILLARITY], or endeavour to produce motion towards each other, has been abundantly demonstrated both by celestial and by terrestrial phenomena. That the parts of solids exercise force on each other is evident from the force which is required to separate them. That the parts of liquids exercise a feeble action of the same kind is also sufficiently obvious. And the common property of most

liquids with respect to solids, namely, that the former wet the latter, is proof of a similar connection between solids and liquids. If glass be

dipped into water and then drawn out, a portion of the liquid is drawn out with it, some of which hangs from the bottom of the glass. Here is sufficient proof of a force which overcomes the weight of the liquid; whatever may be its cause or mode of action, there is an attraction of the particles of the water to those of the glass; but the every day character of the phenomenon did not excite much attention until the appearance of the same kind of effect in a peculiar form, namely, that of capillary attraction, made the experiment a philosophical one.

The preceding figures represent the appearance (in section) of a liquid into which a tube of very small diameter, but enlarged for the sake of distinctness, is plunged. The liquid either rises or sinks in the tube above or below the level of the exterior; and at the same time is slightly curved at what would be, were it not for this curvature, the exterior level immediately adjoining the tube. It is also to be observed that in cases where the liquid stands higher within the tube than without, its upper surface is always concave; but that when the liquid is lower within the tube, it is convex: both appearances are represented in the diagrams. When the solid is one which can be wetted by the liquid, the elevation and concavity are observed; but when the solid appears to repel the liquid, the depression and convexity are observed. Glass and water furnish an instance of the first; glass and mercury of the second. Thus the bulbous appearance of the top of the mercury in a barometer is a phenomenon of the kind represented in the second diagram. [BAROMETER.] The different appearances presented by water and mercury with respect to glass may be thus stated. A drop of water upon a level piece of glass becomes hemispherical or nearly so, and adheres: a very small drop of mercury retains its spherical form, and rolls easily. It is not true that the glass actually repels the mercury; M. Gay-Lussac found that a disc of glass of 120 millimètres, or 4.6 inches, in diameter, required a separating force of from 150 to 300 grammes (a pound avoirdupois is 453½ grammes) to detach it from the surface of a bath of mercury. The inference is that the attraction of the particles of mercury upon mercury is stronger than that of the particles of glass upon mercury, but that the action of glass upon water is stronger than that of water upon water.

The laws according to which the liquid rises or falls have been experimentally determined, and are also found to be deductions from the theory which has been proposed for their explanation. They are as follows: 1. The action of the liquid or solid, of what kind soever it may be, is sensible for a very small extent only; thus a tube of dry glass, and the same tube previously wetted throughout its whole interior with the liquid to be examined, cause different amounts of elevation. In the first case, when the equilibrium is established, the particles in immediate connection with the top of the concavity are of glass: in the second case they are of water, and we are in fact immersing a small tube of water into water, the glass being merely an outer case, on which the water is deposited. The action of the glass appears not to extend the depth of the thin film of water which comes into immediate contact with the water from the vessel. And it is found that whatever the substance may be which serves as a case for the film, the elevation is the same. 2. When cylindrical tubes of different diameters are compared, the elevation is inversely proportional to the diameter: so that in a glass tube of $\frac{1}{100}$ of an inch in diameter water stands twice as high as in one of $\frac{1}{50}$ of an inch; and so on. The height, however, bears no evident ratio to the density or specific gravity of the liquid used, as Muschenbroëck and Gay-Lussac have shown by numerous experiments. 3. Whatever the form of the tube may be, the elevation or depression is found to depend only upon the diameter at the upper part of the elevation: thus, if a small conical tube widening downwards be dipped into a liquid, which is found to rise in it to an elevation at which the tube has a diameter of $\frac{1}{100}$ of an inch, then if a cylindrical tube of $\frac{1}{100}$ of an inch were immersed in the same liquid, the water would rise to the same height as in the conical tube. The converse of this is true, with regard to the pressure of a liquid on the base of a vessel containing it. [HYDROSTATICS.] Hence, if a drop of water be placed in the wide end of a conical tube, it will rapidly move towards the smaller end. The drop, when placed in the tube, becomes doubly concave, the surface nearest the apex of the tube being the more curved of the two; so that the drop moves towards the apex by reason of the attraction of the sides of the tube for the liquid. Laplace has shown that this attraction is inversely as the radius of the curve terminating the liquid column. 4. If the tube be double (one tube within another) the liquid rises to the same height in the interval between the two tubes, as it would do in a tube with that interval for its radius. 5. Between two parallel plates immersed at a very small interval the liquid rises as high as in a tube with that interval for its radius, that is, only one half as high as in a tube having that interval for its diameter. 6. Between two plates vertically placed, but inclined at a very small angle (like a double screen nearly closed) the liquid rises higher and higher as we proceed towards the upright line of junction: and the curve of the upper surface of the liquid is an hyperbola. In fact, if we assume the law mentioned in (2) to be correct, and if we take two sides of the plate, vertical and horizontal as co-ordinates, we have at once the equation:—

$$y = \frac{k^2}{x}$$

y being the height of any part of the curve, or its ordinate, and x its

abscissa, which varies as the interval of the plate *directly*; and k^2 being a constant; hence

$$xy = k^2$$

which is the equation to a rectangular hyperbola referred to its asymptotes.

We shall not give a table of the results obtained by different experiments, because they vary considerably as to amount, though, in the results of the same observer, the fact, marked (2) in the preceding list, generally appears to be very near the truth. The discrepancy probably arises from the various degrees of internal moisture in the tubes. Experiments have been made from the time of Newton, but it is only since the application of the molecular theory by Laplace that it seems to have been always admitted and acted upon, that the internal coating of the tube immediately adjacent to the liquid is the cause of the phenomenon. The results of various observers upon glass and water give elevations of from two to five inches in a tube of one-hundredth of an inch; the result of M. Gay-Lussac (who always observed with moistened tubes, and found all his experiments to agree very nearly with each other) gives an elevation of 4.62 inches for the same diameter. The elevations of liquids vary also with the temperature, the former diminishing as the latter increases. It is, however, remarkable that capillary attraction is able to oppose very strongly the evaporation of the liquids. Fine tubes of glass containing water have been exposed for many months in the sun without losing any appreciable quantity of liquid.

A class of phenomena referable to capillary action is the apparent attraction and repulsion of small bodies floating on water, placed near one another. If one of the bodies only, be composed of a substance capable of being *wetted*, mutual *repulsion* will occur; but if both are incapable of being moistened, mutual *attraction* ensues. When the bodies are *wetted*, the liquid rises around them according to the law of capillarity, but when they are incapable of being *wetted*, the liquid is repelled, and they lie in a *trough*, or hollow depression, and accordingly run together by reason of the lateral pressure of the water beyond, seeming to attract one another.

The phenomena of capillarity discovered by Dutochet in 1828, will be noticed under the head OSMOSE. We shall conclude this article with considerations which may give readers who cannot study the mathematical theory, a notion of the manner in which the phenomena may be supposed to arise, referring to MOLECULAR ATTRACTION for some account of the different modifications which the theory has undergone.

The tube being immersed in the liquid, of which the natural level is AB , let us consider a small canal of liquid $CDEFB$. The glass immediately above C exercises an uncompensated attraction on the liquid; but at any point x between C and D , the action of the glass is equal upwards and downwards, so that there is no further disturbance till we come to D , where the side of the canal ceases to be of glass, and becomes of liquid. There is then at D the difference of the actions of the glass and liquid, *downwards*, if the action of liquid on liquid be the stronger; *upwards*, if that of glass on liquid be the stronger. We suppose the actions to extend to very small distances only. But the counterpoising column BF is in its natural state. If then twice the action of the glass on the liquid (namely, those exerted at C and D) exceeds that of the liquid on the liquid at D , a part of the weight of the column CD is counterbalanced by the excess of upward pressure, and this column, so relieved, cannot counterbalance the weight of BF , unless its length is so increased that the excess of length may counterpoise the upward pressure. The liquid immediately adjoining the side will therefore rise, and the same all round the interior of the tube. But so long as the cohesive quality of the liquid exists, the liquid still more in the interior of the tube will also rise, and this will continue until the whole body of liquid raised is a counterpoise to the inequality of the actions. Similarly, if the action of the liquid at D exceed those of the glass at C and D , there will be a downward pressure equivalent to an increase of weight in the column CD . That column therefore will fall, and with it the column still more in the interior. This explanation, though exceedingly imperfect, will serve to give the first notion on the subject: and the following experiment tends to confirm it. If the tube be filled with liquid, and then held vertically with the lower opening stopped by the finger, which is then gently removed, some of the liquid will drop out, but a column will remain suspended in the tube, ended by a hanging drop from the lower extre-

mity. And it is always found that the length of this column is considerably greater than the elevation when the tube is immersed in the liquid: in fact, the action of the liquid below D on the right is now removed, or a pressure downwards is removed, consequently a longer column is required to counterbalance the actions of the glass at C' and D .

In consequence of the minuteness of the tubes which are required to produce sensible effects, few persons have the means of making experiments on this subject for their own instruction. But a lump of white sugar or a fine sponge, either of which is a collection of minute tubes, held with the lower end slightly immersed, will immediately cause an ascent of the liquid.

CAPITAL is a term used in commerce to express the stock of the merchant, manufacturer, or trader, used in carrying on his business, in the purchase or manufacture of commodities, and in the payment of the wages of labour; and is understood not only of money, but of buildings, machinery, and all other material objects which facilitate his operations in trade. The term itself, and the practical qualities and uses of capital, are sufficiently understood in this its commercial sense. Capital in a more extended sense, as within the province of political economy, may be defined as the products of industry possessed by the community, and still available for use only, or for further production.

To consider capital in all its relations to the material interests of man, to the increase of population, the employment and wages of labourers, to profits and rent, it would be necessary to travel over the entire range of political economy; but this article will be confined to the following points:—I. The origin and growth of capital. II. Its application and uses.

I. A desire to accumulate some portion of the produce of industry being natural to mankind, and nearly universal, the growth of capital may be expected wherever the means of accumulation exist; or, in other words, wherever men are not obliged to consume the whole products of their labour in their own subsistence. From the moment at which a man produces more than he consumes, he is creating a capital; and the accumulated surplus of production over the consumption of the whole community is the capital of a country.

Thus far the origin and growth of capital are perfectly intelligible; but in order to understand completely the progress of accumulation, it will be necessary to advert to certain matters which interfere with its apparent simplicity. A distinction has been drawn between those parts of the products of labour which are reserved for the reproduction of other commodities, and those parts which are intended solely for use or consumption. These two classes of products have been divided by Adam Smith and others into capital and revenue; by which division all products are excluded from the definition of capital unless they be designed for aiding in further production. The impropriety of this distinction, however, has been pointed out by Mr. M'Culloch ('Principles of Political Economy'), and it does not appear that any such division of the stock of a country is founded on a proper distinction. How can its future application be predicated? The fund exists, and so long as it is not sent abroad or consumed it must be regarded as capital. The whole of it may be made available for further production, or the whole may be consumed in present enjoyment; but no part is separable from the rest by an arbitrary classification. The stock has the same capacity for production while in the possession of the owner.

But it must be observed that the accumulation of capital proceeds slowly or rapidly in proportion as one or other of these modes of expenditure is most prevalent. If men habitually consumed or wasted all the results of their industry, it is obvious that the effect of such conduct would be precisely the same to themselves, in preventing accumulation, as if they were unable to earn anything more than was absolutely necessary for their support. It is true that they would enjoy more of the luxuries of life, and, as will presently be seen, their expenditure would conduce, indirectly, to the accumulation of capital by others; but still their labour would only suffice for their own support from year to year, and no part of the produce of last year's labour would be available, in the present year, either for their support or for any other purposes.

As it is evident from these illustrations, that capital must increase in the ratio in which the products of labour exceed the expense of subsistence, it would seem to follow as a necessary consequence that, when a certain amount of capital has already been produced, the higher the rate of profit which may be obtainable from such capital, the greater will be the means of further accumulation. [PROFITS.] It is not necessary, indeed, that larger savings should in fact be made, as that must depend upon the conduct of those who enjoy the profits. Yet, whether savings proportionate to the means of saving be made or not, it is undeniable that a high rate of profit offers the best opportunity for augmenting capital. If three *per cent.* profit upon a man's stock will enable him to subsist as he has been accustomed, and to lay aside one *per cent.* annually as capital, the rise of profit to six *per cent.* would at once give him the power of adding four *per cent.* instead of one, to his capital, so long as he made no change in his style of living: and thus the doubling of the rate of profit would add to the means of accumulation in the proportion of four to one.

But, apart from abstract reasoning, does the experience of different countries bear out the same conclusion? These questions do not always receive the same answer. Mr. M'Culloch compares the progress

of the United States of North America, in wealth and population, with that of England and Holland, and ascribes the comparative rapidity of their advancement to the fact, that the rate of profit is generally twice as high in America as in either of the other countries. ('Principles of Pol. Ec.') He adds, that if the rates of profit have become comparatively low, the condition of a nation, "how prosperous soever in appearance, is bad and unsound at bottom." Professor Jones, on the other hand, denies this inference, and takes a more encouraging view of the state and prospects of our own country. He says, "That fall of the rate of profits, which is so common a phenomenon as to be almost a constant attendant on increasing population and wealth, is, it will be seen, so far from indicating greater feebleness in any branch of industry, that it is usually accompanied by an increasing productive power in all, and by an ability to accumulate fresh resources more abundantly and more rapidly. So far, therefore, is this circumstance from being, as it has hastily been feared and described to be, an unerring symptom of national decay, that it will be shown to be one of the most constant accompaniments and indications of economical prosperity and vigour." ('Distribution of Wealth,' Preface.)

These opinions, apparently conflicting, upon matters of fact, may prove, upon examination, not to be wholly irreconcilable. It is doubtful whether the United States of North America be a good example for the purpose of this inquiry, as there have been many concurrent circumstances in operation in that country, all tending to the same result; and of which high profits may be regarded as the effect rather than the cause. It will be safer, therefore, to confine the examination of the effects of high profits upon accumulation to our own country at different times.

First, then, it will be admitted on all hands that individual fortunes have been more rapidly accumulated in England at those times in which the profits in particular departments of industry were the highest. This admission is no more, in other words, than the truism, that when a trade is prosperous money is made by it. The next question is, whether a high rate of profit in all departments of industry has the same effect in augmenting the sum total of national capital. Political reasoners are too apt to assume a universal analogy between individuals and nations, which is often deceptive, and leads to inaccurate conclusions. In the present instance, if this analogy were allowed, it would be decisive of the whole question, and would exclude all observation of facts. The fact, as stated by Professor Jones, is undeniable, that a fall in the rate of profits is the ordinary accompaniment of increasing population and wealth. There is more capital in England and in Holland, in proportion to the population, than in any country in the world, and in those countries the rate of profit is the lowest. The resources of England have been increasing in an extraordinary manner during the last half century; and, at the same time, the more evident the wealth of the country has become, the lower has fallen the general rate of profits.

The examination of the causes of profit is reserved for a separate article [PROFITS]; but here it may be stated that a fall in the rate of profits is the inevitable result of enormous accumulations of capital. Capitalists are forced into competition with each other, and are ultimately obliged to content themselves with lower profits. But in the meantime, does the aggregate accumulation of national wealth diminish? This inference is contradicted by all the statistics which illustrate the progress and present condition of Great Britain. All evidence shows that British capital is positively overflowing, and seeking employment in every enterprise at home or abroad.

This fact, it is submitted, is nevertheless consistent with the general proposition, that high profits are favourable to accumulation. In calculating the aggregate savings of a people already rich and populous, it must be borne in mind, first, that the existing generation has inherited the accumulations of many preceding generations; and, secondly, that a large number of persons continually saving a small portion of their individual gains may produce a greater aggregate accumulation than the larger proportionate savings of a less number of persons.

With reference to the first point, it need only be observed, that if the inherited capital be not squandered or wasted, its annual interest alone affords the means of enormous accumulation; while the rent of land, the profits of trade, and the wages of labour, are continually supplying new funds for further production and accumulation. The second point may be made clearer by an illustration. Let us suppose one hundred men, each saving 100*l.* annually out of their profits. Their aggregate accumulations would amount to 10,000*l.* But suppose one thousand men, with equal capitals, but unable, on account of a lower rate of profit, to save more than 50*l.* a year; their aggregate accumulations would amount to 50,000*l.* In both cases they would have maintained themselves and their families out of their profits, and have paid the wages of all the labour required in their business; after which their savings remain available for increased production, and for the employment of a larger quantity of labour. This example falls far short of the circumstances of Great Britain, for the number of small capitalists is even more extraordinary than the enormous capitals possessed by a comparatively small number of wealthy men; and their annual additions to the national capital are of incalculable amount.

The conclusions to which we are led by these inquiries, are—that a high rate of profit is favourable to accumulation; that rich and populous countries are denied this advantage; that if they enjoyed it,

their capital would continue to increase more rapidly than it does, in fact, increase; but that under ordinarily favourable circumstances, the masses of inherited capital and the aggregate savings of vast numbers of capitalists still facilitate accumulation in a greater ratio than the increase of population.

II. The consideration of the application and uses of capital will be disembarassed of much complexity by explaining, at the outset, the distinction raised by political economists between what is called productive and unproductive labour and expenditure. The end of all production is use or consumption: some products are immediately destroyed by the use of them, as food or coals; others are consumed more slowly, but are ultimately destroyed by use, as clothes or furniture: but whatever is the durability of the thing produced, its sole use is the enjoyment of man. A man is rich or poor according to his power of obtaining the various sources of enjoyment which the skill and industry of others produce; and the aggregate of such permanent sources of enjoyment constitutes the wealth of nations. Whatever labour or expenditure, therefore, may be devoted to the increase or continuance of those sources of enjoyment, must be deemed productive: and labour and expenditure, which have no such tendency, must be viewed as unproductive.

The most scientific classification of productive and unproductive descriptions of labour and expenditure which we have met with is that of Mr. Mill. According to his definition the following are always productive:—When their "direct object or effect is the creation of some material product useful or agreeable to mankind," or "to endow human or other animated beings with faculties or qualities useful or agreeable to mankind, and possessing exchangeable value:" or "which, without having for their direct object the creation of any useful material product, or bodily or mental faculty or quality, yet tend indirectly to promote one or other of those ends, and are exerted or incurred solely for that purpose." Labour and expenditure are said to be unproductive when they are "directly or exclusively for the purpose of enjoyment, and not calling into existence anything, whether substance or quality, but such as begins and perishes in the enjoyment;" or when they are exerted or incurred "uselessly or in pure waste, and yielding neither direct enjoyment nor permanent sources of enjoyment." ('Essays on Unsettled Questions of Political Economy,' Essay III.) Examples of these several classes would transgress our limits, but a study of the above definitions may serve to correct an erroneous impression, that no expenditure is productive unless it be incurred directly in aid of further production.

The employment and aid of productive industry is the most important end of capital. Its first and most important use is the division of employments, which, though necessary for any advance in arts, is impracticable without some previous accumulation of capital. Until there is a fund for employing labour, every man's business is the seeking of his own daily food; but as soon as the capital of another secures that for him, his labour is available for the general good. The more capital is accumulated, the more extended are the facilities for indefinite distribution of employments, according to the wants of the community.

Capital may be applied either directly in the employment of labour, or directly in aid of labour: it may be spent in the food and clothes of labourers, or in tools and other auxiliary machinery, to assist their labour and increase its productiveness. The former is usually termed circulating capital, and the latter fixed capital. Both are equally essential to the progress of the arts and national wealth, and are used in combination; but the effects produced by each are not always the same. If a farmer employs three labourers, and his capital is afterwards doubled, it is a very important question whether he expend his increased stock in the payment of three additional labourers, or in providing auxiliary machinery to increase the power of the three labourers, already employed. In the latter case we may be assured that his machinery will do the work of more than three men; for otherwise no ingenuity would have been applied to its contrivance. It is truly said by Professor Jones, that "when, instead of using their capital to support fresh labourers in any art, (a people) prefer expending an equal amount of capital in some shape in which it is assistant to the labour already employed in that art, we may conclude with perfect certainty, that the efficiency of human industry has increased relatively to the amount of capital employed." ('Distribution of Wealth,' p. 222.) The same able writer has pointed out another difference in the results of auxiliary capital, namely, "that when a given quantity of additional capital is applied, in the results of past labour, to assist the labourers actually employed, a less annual return will suffice to make the employment of such capital profitable, and therefore permanently practicable, than if the same quantity of fresh capital were expended in the support of additional labourers." (Ibid. p. 224.) This circumstance arises from the greater durability of the fixed capital, which may not require renewal for several years, while the direct expenditure on labour must be renewed annually. Thus 100*l.* spent in labour to cause a profit of 10 per cent. must produce results amounting in value to 110*l.*: but the same sum expended upon any machinery calculated to last for five years would be equally well repaid by a return of 30*l.* a year; being 10*l.* for profit upon the outlay, and 20*l.* for the annual wear and tear of the capital.

Not only does capital facilitate divisions of employment, and in-

crease the productiveness of industry, by which the enjoyments of man are multiplied, but it actually produces many sources of power and enjoyment, which without it could have no existence. It is the foundation of all social progress and civilisation, for without it man is but a savage. It must precede his mental culture, for until it exists his noble endowments are idle or misemployed. Without it, his mind is a slave to the wants of his body: with it, the strength of others becomes subservient to his will, and while he directs it to increase the physical enjoyments of his race, his intellect ranges beyond the common necessities of man, and aspires to wisdom—to government and laws—to arts and sciences. In all the nations of the world riches have preceded and introduced intellectual superiority. In numberless processes of art capital enables work to be executed which could not otherwise be performed at all, or enables it to be performed better and in less time. In all ways it multiplies indefinitely the varied sources of enjoyment that are offered to civilised man; but never more conspicuously than when it stimulates and encourages invention.

The paramount value of capital to the prosperity of a nation should never be overlooked by a government. Unwise laws, restrictions upon commerce, improvident taxation, which are unfavourable to its growth, should be dreaded as poison to the sources of national wealth and happiness. No class is the better for its decay or retarded growth: all derive benefit from its increase. And above all, when population is rapidly increasing, let a government beware how it interferes with the natural growth of capital, lest the fund for the employment of labour should fail, and the numbers of the people, instead of being an instrument of national power, should become the unhappy cause of its decay. The material happiness of a people is greatest when the national wealth is increasing more rapidly than the population; when the demand for labour is ever in advance of the supply. But while the natural growth of capital should not be interfered with by restrictions, the opposite error of forcing it into particular channels should equally be avoided. Industry requires from government nothing but freedom for its exercise; and capital will then find its own way into the most productive employments. The best means of aiding its spontaneous development are a liberal encouragement of science and the arts, and a judicious system of popular education and industrial training; for as "knowledge is power," so it is at once the best of all riches and the most efficient producer of wealth.

CAPITAL. [COLUMN.]

CAPITE, TENANTS IN. [BARON.]

CAPITOL, CAPITO'LIUM, MONS CAPITOLI'NUS, a hill, a fortress, and a temple, celebrated in the history of ancient Rome. The temple and the fortress no longer exist; and the hill is called by corruption Campidoglio. It rises on the eastern skirts of the inhabited part of modern Rome, which it divides from the Forum and the other forsaken districts of the ancient city. The Capitoline Mount is of an oval shape, and about one mile in circumference at its base; it is divided from the Quirinal to the N.E. by a narrow valley, in which the Forum of Trajan once was, and the pillar still is; it has to the E. the Forum of Augustus and the Via Sacra, which divides it from the Esquiline hill; to the S.E. the valley of the Forum Romanum, which divides it from the Palatine hill; to the S. the Forum Boarium, which divides it from the Aventine hill; and the Tiber to the S.W. It has two summits, one to the N. towards the Quirinal, on which the church and Franciscan convent of Ara Coeli now stand; and another to the S. towards the Tiber, on which are the palace and garden of Caffarelli. At the S. end was the Tarpeian rock, down which state-criminals were hurled. The height of this side of the hill is very much reduced, the ground at the foot of it having been considerably raised by ruins and rubbish, and the rock itself having been sloped down, and houses built against it. Still it rises abruptly in one place, to the elevation of 80 palmi (65 feet), at the back of the Caffarelli gardens, above Piazza Montanara. The height of the Capitol, taken at the pavement of the church of Ara Coeli, which is the highest summit, is 155 feet above the sea, 135 feet above the Tiber taken at its medium height, and about 90 feet above the present surface of the Forum, which however is in several places 20 feet higher than its ancient level.

The hill is said to have been called Saturnius in the ante-Roman times. When the first Romans built their town on the Palatine, they chose the opposite hill, which was then more abrupt, to build their arx or citadel upon. In their first war with the Sabines, according to the old story, the latter took possession of this stronghold by the treachery of a woman called Tarpeia, the daughter of the Roman commander. Hence the hill took the name of Tarpeius. After the peace Tatius and his Sabines settled on the Tarpeian Mount, and Romulus remained on the Palatine. Tarquinius the Elder began to build a temple to Jupiter on the Tarpeian Mount, the summit of which he levelled for the purpose. The building was afterwards continued by Tarquinius Superbus, who engaged workmen from Etruria for the purpose, and employed in it the money resulting from the plunder of Suessa Pometia, a city of the Volsci, which he had taken and destroyed. Wishing the place to be wholly consecrated to Jupiter, he ordered the chapels and votive altars erected by Tatius and others to be removed. The augurs consulted the flight of birds to ascertain the will of the gods, and all were declared to have assented except the god Terminus, who would not stir from his place. This was considered as an omen of the perpetuity of the new edifice and of the city. In digging some

part of the foundations, the workmen were said to have found a human head quite fresh, which was interpreted to signify that the spot would be the head and centre of the Roman power. (Livy, i. 55.) The temple was accordingly dedicated to Jupiter Capitolinus, from caput, "a head." It has been a subject of dispute whether this temple stood on the N. or S. summit of the hill; it seems probable, however, that it stood on the N. side, where the church of Ara Coeli now stands. (Nardini, Ficoroni, &c.) It is said to have stood *in arce*, "in the citadel," which was originally on the S. summit; but as the entire mount was afterwards inclosed by walls and fortified, the word arx was used indiscriminately for the whole. The temple is said to have had its front to the S. towards the Aventine; had it been at the S. extremity, there would have been no access to it, except at the back, by the Clivus Capitolinus. This is one of the arguments used by Nardini and others. The temple of Jupiter Capitolinus was burnt in the civil war of Marius, but Sulla rebuilt it with much greater splendour and of the most costly materials. It is said to have been 200 feet long and 185 wide; it had a peristyle with three rows of marble columns in front, and two rows of pillars divided the interior into three aisles, at the furthest end of which were three cellæ dedicated to Jupiter, Juno, and Minerva. The vault of the temple and the external roof were covered with plates of gold. This temple was the principal sanctuary of Rome, to which the victorious generals and emperors went in triumphal procession to sacrifice to the gods. Other temples were raised successively on the Capitoline hill, such as that of Juno Moneta, with the mint annexed to it; of Jupiter Feretrius, said to have been built by Romulus; of Mars, of Venus, of Fortune, and of Isis and Serapis. The temple of Concord stood on the slope towards the Forum. A Bibliotheca or Library, the Tabularium, Athenæum, Curia Kalabra, the Atrium publicum, and other public buildings, were also in the Capitol. In the intermontium or little valley between the two summits, stood the Asylum or place of refuge, between two plantations of oak trees. It is difficult now to form an idea of the appearance of the place and the effect it must have produced. It is evident that the sides of the hill were much more abrupt and stood higher above the plain below than at present. The only access was from the Forum on the S. side by the Clivus Capitolinus and the Clivus juxta Asylum. There were also 100 steps to ascend to the Tarpeian rock, being probably an opening on that side branching out of one of the two Clivi.

The principal buildings of the modern Capitol consist of three palaces, the work of Michel Angelo, forming three sides of a square, in the middle of which stands the equestrian statue of Marcus Aurelius. The open side is to the N.W. towards the modern city. The palace facing it is that of the senator of Rome; to the left of it is the palace de' Conservatori; and to the right that of the Capitoline Museum, one of the finest collection of statues and sculptures in Italy. The three palaces and the square between occupy the intermontium, the two summits being occupied by the church of Ara Coeli and the palace and gardens of Caffarelli. Two ways lead down by the senatorial palace into the Campo Vaccino, or ancient Forum.

CAPITULARIUM, literally "a book divided into chapters," was the name given to the laws issued by the French kings of the first and second races, in the great assemblies of the nobles and bishops which formed the states of the kingdom, for the administration of civil and ecclesiastical affairs. These laws, being classed under heads or chapters, were called capitularies. Childebert, Clotarius, and Dagobert, and afterwards Charlemagne, Louis le Débonnaire, Charles the Bald, &c., issued capitularies. Those of Charlemagne are the most celebrated, being more extensive, more enlightened considering the age he lived in, and forming a real code of legislation which remained in force long after. Ansegisus, abbot of Fontenelles, made a collection in books of the capitularies of Charlemagne and his son Louis le Débonnaire in the year 827. Other collections were published subsequently. After Charles the Simple, A.D. 922, no more capitularies were issued, and no laws or statutes are known to exist of the subsequent period till the time of Louis le Gros, A.D. 1100. Louis le Gros began to issue charters to the communes or churches, but no general laws or ordinances appear to have been enacted, except one by Philippe Auguste in 1190, till the time of St. Louis, A.D. 1260, who began to issue regular ordinances. Baluze published a complete collection of all the capitularies issued by the kings of the first and second race, with notes. (*Capitularia Regum Francorum*, 2 vols. folio, Paris, 1677.)

CAPITULATION, a series of articles expressing the conditions under which a fortress is surrendered to an enemy.

The agreement by which an army or a large division of troops surrenders to a superior force, or engages to evacuate the territory which it occupies, when its strength and condition are yet such as to make itself respected by the enemy, is called a Convention. Such was that made at Cintra, or rather at Lisbon, between the generals of the French and English armies on the departure of the former from Portugal in 1808.

When the provisions and ammunition of a garrison are nearly expended, when breaches have been made in the ramparts of the fortress, and no chance remains of being succoured, the governor of the place is justified in entering into an agreement with the besiegers respecting the terms by which he consents to deliver his charge into their hands; and by the rules of war, as well as from the regard due to a gallant

adversary, he is entitled to obtain an honourable capitulation. It may be observed, that if the governor should postpone the proposals to surrender till his provisions are entirely exhausted, the besiegers may refuse to grant terms to the garrison, which must then surrender at discretion.

When the reign of Napoleon was drawing to an end, and he found himself reduced to the necessity of acting on the defensive, the duty of defending the fortresses of France was impressed on the commanders by every motive which the love of glory and the fear of disgrace can inspire. In the Imperial decree concerning them, it is stated that every commander who shall appear to have defended his fortress like a man of honour and a faithful subject, shall, along with the officers and soldiers who may have distinguished themselves in the defence, be presented on a day of general parade, and receive, in presence of the troops, public testimonials of the emperor's satisfaction; that no time shall be lost in exchanging those who may be made prisoners of war; and that every commander who shall be killed on the breach, or die of his wounds, shall be buried with the same ceremonies as a Grand Cross of the Legion of Honour. On the other hand it is stated, that every capitulation made without a vigorous resistance continued to the last moment, and without having sustained at least one assault on the rampart of the place, is criminal and dishonourable: the commander who so surrenders is made responsible for all the consequences of his cowardice or treachery; he is threatened with all the severity of the law; and the decree consigns to infamy, and punishes with death, him who yields to the menaces or proposals of the enemy.

If the resolution to surrender should be at length taken, the conditions solicited by the governor should be expressed concisely in a few articles, and should be such only as he can expect to obtain consistently with the circumstances of the case. The governor should, however, firmly insist upon their execution when granted. He is not to separate himself from his garrison, but he must share its fate as well after as during the siege; and he is to stipulate in favour of the sick and wounded for as many advantages as he can possibly gain.

It has happened that the governor of a fortress has been induced to leave his post by an invitation to a personal conference with the general of the besieging army, and that advantage has been taken of his absence to assault the place in the hope of gaining it during the confusion then expected to prevail there. History moreover records instances in which the besieging troops have entered the place and committed disorders even while the commanders have been occupied on the breach in drawing up the articles of the capitulation. To avoid such misfortunes the governor of a fortress should on no account go out for the purpose of treating with the enemy, but he must employ in that duty officers on whose zeal and firmness he can rely.

By the terms of a capitulation the arms and military stores in the place are generally given up to the besiegers; the officers and troops of the garrison retaining only their private property, and being allowed to march out with the honours of war, that is, with drums beating, colours flying, &c. When necessary, a convoy is allowed them for protection till they arrive at the place of their destination.

CAPIVIC ACID ($C_{40}H_{80}O_4$). A resinous acid isomeric with pinic acid, and found in balsam of capivi. [BALSAM.]

CAPNOMOR is a colourless, limpid, volatile oil, obtained by Reichenbach, with several other products, from the heavy oil of tar. Its odour resembles that of ginger, and it has a styptic after taste. Its density is 0.9775. It is perfectly neutral, boils at 345° Fahrenheit, and distils unaltered. It burns with a sooty flame. It is very slightly soluble in water, but dissolves in alcohol, ether, essential and fixed oils. It dissolves phosphorus, sulphur, and selenium. It combines with chlorine, emitting hydrochloric acid. It mixes with sulphuric acid, and imparts to it a red colour; nitric acid converts it into oxalic acid, carbazotic acid, and another crystalline substance which has not yet been examined. Acetic acid takes up capnomor, and it dissolves several organic acids; potassium and sodium act but slightly upon it, and the alkalies and alkaline earths decompose it but slowly. It has not been analysed.

CAPONNIÈRE, in fortification, is a passage protected on the right and left by a wall or parapet. The term is generally applied to that by which the communications are made across the main ditch of the fortress to the outworks [BASTION, G. fig. 1], or from the covered-way to the gorge of an advanced work. When a passage exposed on one side only is thus protected, it has the name of a demi-caponnière.

The projecting parapet is generally of earth, with its upper surface descending gradually to the bottom of the ditch, in order that the enemy may be completely exposed in advancing up to it, and also that the ditch may be defended by a grazing fire from thence. A passage of this kind is however exposed to the plunging fire of the enemy from the crowning battery H, and from that which should correspond to it on the left hand of the front of the fortification; it may therefore be further protected by a parados or elevation of earth extending along its centre; for by this the defenders behind both parapets would be effectually concealed.

Sometimes the caponnière is a vaulted gallery of brickwork, the sides of which are pierced with loop-holes or narrow openings, for the defence of the ditch by a fire of musketry. In this case a trench is cut on the exterior, and parallel to each side of the work, in order to

prevent the enemy from approaching near enough to annoy the defenders within.

Palisade caponnières are formed across the ditches of field-redoubts when those ditches are incapable of being defended from the parapets. If covered with a roof for protection against shells or grenades, that roof should be kept below the level of the natural ground, in order that it may be concealed from the view of the enemy at a distance.

CAPRAL. [RUTIC ACID.]

CAPRAMIDE. [RUTIC ACID.]

CAPRIC ACID. [RUTIC ACID.]

CAPRICORN, TROPIC OF. [TROPICS.]

CAPRICORNUS, the tenth constellation in the zodiac, as a constellation, but the part of the moveable ecliptic between 270° and 300° of longitude was also so designated. [ECLIPTIC.] This constellation never rises in our latitude to a greater altitude than 25° , or thereabouts (we speak of the largest stars, α and β , in the horn). Around it, in the visible portion of the heaven, are Aquarius, Equeleus, Delphinus, Aquila, and Sagittarius. The brightest stars, α and β , are on the meridian at midnight towards the end of July. A line drawn through the bright stars in Lyra and Aquila will, when lengthened, not pass far from the two brightest stars in Capricornus, α and β .

The upper half of Capricornus is that of a goat, and the lower half that of a fish. In some of the Eastern zodiacs it is altogether an alligator or sea monster. According to Hyginus, Jupiter fixed this constellation in the heavens in admiration of the ingenuity of Pan, who, when the gods were obliged to escape from the giants in the form of various animals, made himself half goat and half fish, and lived in a river.

The following are the principal stars:—

Character.	No in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
α^1	5	6972	4
α^2	6	6974	3
β	9	6995	3
ϵ	39	7506	4
γ	40	7525	4

CAPRIFICATION, the process by which the maturation of the fig is accelerated in the Levant. It is imagined that fruits which have been bitten by insects ripen sooner than others, the wound appearing to act as a stimulant to the local action of the parenchyma. This is imitated by the Greeks in the following manner, which is called caprification. When the cultivated fig is preparing for becoming ripe, a quantity of the branches of the caprifig or wild fig-tree are brought into the fig orchards and placed upon the cultivated plants. The wild figs are said to bring with them a great number of small insects called *Cynips Psenes*, or *Diptolepis Ficus Caricæ*, which fly among the cultivated figs and pierce their fruit for the purpose of laying eggs. This they say not only brings about an earlier ripening of the fig crop than would otherwise be obtained, but enables the cultivator to obtain two harvests a year. It is, however, thought that the practice deteriorates the quality of the fruit. Caprification has been artificially imitated by puncturing a fig with an awl, and introducing a little oil into the wound, for the purpose of preventing its healing too soon. (De Candolle, 'Physiol. Végétale,' p. 580; and Treviranus in the 'Linnæa for 1828,' p. 70, tab. 1, fig. 1 and 2, in which last place the insect is figured.) But experiments do not confirm these popular statements; on the contrary, they show them to be mere fallacies. Professor Gasparini, a learned Sicilian botanist, has shown satisfactorily that the *Diptolepis* "neither hastens the maturity of the fig nor causes it to set, nor yet is necessary for that purpose." (See his 'Memoir on Caprification,' translated in the 'Journal of the Horticultural Society,' iii. 185.)

The kind of caprification above-mentioned must not be confounded with another sort, of very high antiquity, that is practised with the date palm, and which has been mentioned by Herodotus (i. 193). In this latter case the clusters of male flowers from wild date trees are brought and shaken over the clusters of cultivated females, which are thus fertilised and enabled to ripen. It is obvious that the two cases are essentially different, although confounded under one common term. In the fig the *Cynips Psenes*, brought by the wild branches, punctures the cultivated figs, which is said to accelerate their ripening; in the palm the pollen of the wild males is shed upon the stigmas of the cultivated females, and fecundates them.

CAPROATES. [CAPROIC ACID.]

CAPROIC ACID ($C_{12}H_{24}O_4$). This acid, which was discovered by Chevreul, exists either in the free state or in combination with glycerine, in cow's and goat's butter, and also in considerable quantities in cocoa-nut oil. In the series of fatty acids of the general formula $C_nH_{2n}O_4$ it is the member next higher than valerianic acid. It is now seldom prepared from butter, in which it was first discovered. It may be prepared from cocoa-nut oil by saponifying the oil with potash, and distilling the soap with excess of dilute sulphuric acid. The distillate which contains caproic and caprylic acids is neutralised by baryta, the solution evaporated to dryness, and the mixture of the two salts separated by treatment with alcohol, in which the caprylate of baryta

is insoluble, while caproate readily dissolves. From the baryta salt the acid is separated by means of sulphuric acid.

The most advantageous mode of preparing caproic acid is by the action of potash on cyanide of amyl.

Cyanide of amyl is boiled for some time with alcoholic solution of potash, large quantities of ammonia escape, and after some time the residue solidifies to a crystalline mass of caproate of potash. This salt is dissolved in a small quantity of water, and a slight excess of sulphuric acid added, by which the caproic acid is liberated in the form of an oil, which floats on the surface. This is rectified and the distillate between 388° and 392° Fahr. collected separately.

Caproic acid is a colourless oily liquid, with an odour at once suggestive of vinegar and of sweat; its taste is acid and sharp, with a sweetish aftertaste. Its density is 0.930. It boils at 388° Fahr. It is soluble in about 90 parts of water, and dissolves in all proportions in alcohol and ether.

Wurtz has observed that caproic acid prepared from cocoa-nut oil, and that prepared from cyanide of amyl, though identical in other respects, differ in this—that while the former is optically inactive, the latter has the property of rotating the plane of polarisation. As all derivatives of amylic alcohol which contain the radical amyl ($\text{C}_{10}\text{H}_{11}$) have been observed to possess this rotatory power, Wurtz concludes, as Kolbe and Frankland had previously done on other grounds, that caproic acid also contains this radical, and is formic acid in which hydrogen is replaced by the radical amyl.

The caproates are monobasic, and have the general formula $\text{C}_{12}\text{H}_{11}\text{MO}_2 = \text{MO C}_{12}\text{H}_{11}\text{O}_2$.

Caproate of potash ($\text{KO, C}_{12}\text{H}_{11}\text{O}_2$) forms a transparent jelly which becomes opaque by heat. When a solution of this salt is electrolysed, hydrogen and carbonic acid gases are given off, and an oil is formed which is the radical amyl ($\text{C}_{10}\text{H}_{11}$), containing an admixture of caproic acid.

Caproate of baryta ($\text{BaO, C}_{12}\text{H}_{11}\text{O}_2$) crystallises according to the temperature at which it is evaporated, either in large needles or in brilliant hexagonal plates. It fuses at a gentle temperature, and by dry distillation yields gaseous hydrocarbons and a small quantity of a colourless oil, which is a mixture of caproic aldehyde ($\text{C}_{12}\text{H}_{12}\text{O}_2$), and of caprone, $\text{C}_{22}\text{H}_{22}\text{O}_2 = \text{C}_{12}\text{H}_{11}\text{O}_2$, the ketone of the series.

Caproate of ethyl, or caproic ether ($\text{C}_{16}\text{H}_{16}\text{O}_4 = \text{C}_4\text{H}_5\text{O, C}_{12}\text{H}_{11}\text{O}_3$), is obtained by distilling a mixture of caproate of baryta, alcohol, and sulphuric acid. It is a limpid oil, boiling at 324° F., and possessing a pleasant odour of pine-apples.

Anhydrous caproic acid ($\text{C}_{12}\text{H}_{11}\text{O}_2$) is prepared by the action of oxychloride of phosphorus on caproate of baryta. It is an oil lighter than water, and perfectly neutral.

CAPROIC ALCOHOL, or Hydrated Oxyde of Hexyl, $\text{C}_{12}\text{H}_{14}\text{O}_2 = \text{C}_{12}\text{H}_{13}\text{O, HO}$. This alcohol is contained in very small quantities in the less volatile parts of the brandies prepared from the expressed residue of the grape, along with its homologous propylic, butylic, and amylic alcohols. It is separated by fractional distillation. It is a colourless aromatic highly refracting liquid, insoluble in water. Its density is 0.832, and it boils at about 302° Fahr. As far as it has been examined, it exhibits all the re-actions of an alcohol. By the action of potash it is converted, with disengagement of hydrogen, into caproate of potash, and with sulphuric acid it forms a copulated acid homologous with sulphovinic acid.

Hexyl, $\text{C}_{12}\text{H}_{13}$. The radical of caproic alcohol, so called from being the sixth in the series of homologous radicals, was obtained by Brazier and Gossleth by the electrolysis of cenanthylic acid, in the same manner in which the radical methyl is obtained by the electrolysis of acetate of potash.

During the operation the hexyl separates as an oily layer on the surface of the solution. It contains other substances admixed, resulting from secondary action, and is freed from them by distillation with potash and subsequent rectification. It is a fragrant oil, boiling at 397° Fahr. It is a very permanent body. It is not attacked by sulphuric acid or by moderately strong nitric acid, but by a mixture of the two it is partially oxidised and changed into a fatty acid, which is probably caproic acid. This radical, or its isomer $\text{C}_{24}\text{H}_{25}\text{H}$, has also been found by G. Williams, as a component of certain oils formed by the destructive distillation of boghead cannel coal.

CAPROIC ALDEHYDE. [CAPROIC ACID.]

CAPROIC ETHER. [CAPROIC ACID.]

CAPROILENE. [HEXYLENE.]

CAPRONE. [CAPROIC ACID.]

CAPRONITRILE, or Cyanide of Amyl, ($\text{C}_{10}\text{H}_{11}\text{C}_2\text{N}$), is obtained by heating a mixture of caproate of ammonia and anhydrous phosphoric acid, or by distilling together sulphamylate of potash and cyanide of potassium. By boiling with alcoholic solution of potash it is converted into caproic acid. [CAPROIC ACID.]

CAPROTYL. [CAPROIC ALCOHOL: Hexyl.]

CAPRÖYL ($\text{C}_{12}\text{H}_{11}\text{O}_2$), the hypothetical negative radical of caproic acid, which is generally regarded as the hydrated oxide of capröyl, $\text{C}_{12}\text{H}_{11}\text{O}_2 \left\{ \begin{array}{l} \text{H} \\ \text{O}_2 \end{array} \right.$.

CAPRYLAMINE. [CAPRYLIC ALCOHOL.]

CAPRYLENE. [CAPRYLIC ALCOHOL.]

CAPRYLIC ACID ($\text{HO, C}_{16}\text{H}_{15}\text{O}_2$) occurs in cow's and goat's butter, in cocoa-nut oil, and in other fatty matters along with acids homologous with it; and is also frequently formed by the oxidation of fatty substances. Its best source is cocoa-nut oil. It is prepared by decomposing the caprylate of baryta [CAPROIC ACID] by sulphuric acid.

At ordinary temperatures it is an oily liquid, of a sudoriferous odour. At 50° Fahr. it crystallises in needles. It boils at 457° Fahr. It is a monobasic acid, the general formula of its salts being $\text{MO, C}_{16}\text{H}_{15}\text{O}_2$. They have been but little examined.

Caprylic ether or caprylate of ethyl ($\text{C}_4\text{H}_5\text{O, C}_{16}\text{H}_{15}\text{O}_3$) is a colourless liquid, with an odour like that of pine-apples.

CAPRYLIC ALCOHOL, or hydrated oxide of capryl ($\text{C}_{16}\text{H}_{15}\text{O}_2$) This alcohol is also called octylic alcohol ($\alpha\kappa\tau\omega$, eight), as being eighth in the series of homologous alcohols. It is formed by distilling ricinoleic acid with excess of potash, or more simply by distilling castor oil itself, which consists of ricinoleic acid in combination with glycerine, with excess of caustic potash. The action is tolerably brisk, hydrogen is given off, and an oily liquid passes over, consisting mainly of caprylic alcohol, while sebacic acid is formed, and remains in combination with the potash.

Besides caprylic alcohol, the oily liquid contains a ketone methyloenan-thol $\text{C}_{16}\text{H}_{16}\text{O}_2 = \text{C}_{16}\text{H}_{15}\text{O}_2 \left\{ \begin{array}{l} \text{C}_2\text{H}_3 \\ \text{C}_2\text{H}_3 \end{array} \right.$. This is removed by agitating the liquid with bisulphite of potash, with which it forms a crystallised compound.

Caprylic alcohol when pure is a colourless oleaginous liquid of an agreeable aromatic odour, insoluble in water, but soluble in alcohol and ether. It boils at 362° Fahr. Exposed to the air, it gradually acidifies—this change is greatly accelerated by platinum black. It forms, with chloride of calcium, a crystalline, easily decomposable compound. By the action of chloride of zinc, it is decomposed with the formation of hydro-carbons, the most abundant of which is an oily liquid, caprylene (octylene) $\text{C}_{16}\text{H}_{16}$.

By the action of caustic alkalies, caprylic alcohol is decomposed with the disengagement of hydrogen, and formation of caprylic acid.

Capryl ($\text{C}_{16}\text{H}_{17}$), the radical of these compounds is obtained by treating chloride of capryl with sodium.

Chloride of capryl ($\text{C}_{16}\text{H}_{17}\text{Cl}$), a liquid of an agreeable fruity odour, is formed by treating caprylic alcohol with hydrochloric acid.

Iodide of capryl ($\text{C}_{16}\text{H}_{17}\text{I}$), and Bromide of capryl ($\text{C}_{16}\text{H}_{17}\text{Br}$), are formed by treating the alcohol with the iodide or bromide of phosphorus. By the action of ammonia on iodide of capryl caprylamine

$\text{C}_{16}\text{H}_{17}\text{N} = \text{C}_{16}\text{H}_{17} \left\{ \begin{array}{l} \text{H} \\ \text{H} \end{array} \right. \text{N}$ is formed: it is a colourless limpid liquid, with an ammoniacal odour, which slightly resembles mushrooms. It forms readily crystallisable salts.

By the action of iodide of capryl on the metallic compounds of the alcohols, Wills obtained a series of double ethers. Of these, the methyl-caprylic ether ($\text{C}_2\text{H}_3\text{O, C}_{16}\text{H}_{17}\text{O}$), the ethyl caprylic ether ($\text{C}_4\text{H}_5\text{O, C}_{16}\text{H}_{17}\text{O}$) and the amyl caprylic ether ($\text{C}_{10}\text{H}_{11}\text{O, C}_{16}\text{H}_{17}\text{O}$) have been described.

Sulphocaprylic acid ($\text{C}_{16}\text{H}_{17}\text{O, HO, 2SO}_3$) is formed by the action of strong sulphuric acid on caprylic alcohol. It forms crystallised salts, and is homologous in all respects with sulphovinic acid.

CAPRYLIC ETHER. [CAPRYLIC ACID.]

CAPS, PERCUSSION. There have been three modes adopted, in different times, for firing off muskets, fowling-pieces, and other kinds of hand-guns, namely, the match, the flint and steel, and the percussion cap; the last of which depends for its principle on modern chemical discoveries.

It has been stated [ARMS] that the first kind of hand-gun, called the hand-cannon, was fired by a match applied to the priming at the touch-hole; and that the first approach towards the use of a gun-lock was by placing a small pan at the right hand of the touch-hole to contain the priming-powder, to prevent it from being blown away. The match was applied by hand; but in the arquebus, a later invention, it was brought over the touch-hole by means of a trigger, such as had before

been used for shooting the arrow from a cross-bow. Next came into use the wheel-lock, in the time of Henry VIII.; this was a contrivance by which sparks of fire were elicited from a furrowed steel wheel, by friction against a piece of pyrites, or sulphuret of iron; the trigger acted on a lever and chain which made the wheel revolve, and also brought the piece of pyrites down in contact with it, so that the grating of the two together might produce a spark sufficient to kindle the priming of the gun. The next improvement consisted in the substitution of a flat furrowed piece of steel for the wheel, and a piece of flint for the pyrites. By gradual improvements made from time to time, the complicated arrangement of the flint and steel assumed a considerable degree of perfection, and made the gun-lock a very curious piece of machinery. The manufacture of these locks used to form an important branch of Wolverhampton trade; while the manufacture of the flints, especially during times of war, was largely carried on in various parts of England and the Continent where the best flints were found.

The employment of percussion caps, instead of the above contrivances, arose out of the discovery of certain chemical substances which will explode by percussion or a blow without the aid of heat. Such substances are called detonating or fulminating compounds; and the idea of employing them for firing muskets is said to have originated in the following manner:—About the year 1793, on account of a scarcity of saltpetre in France, the French government caused experiments to be made to determine how far a certain preparation of chlorate of potash would answer as a substitute for gunpowder. The attempt was, from various causes, unsuccessful; but it suggested to the mind of Mr. Fordyce, a gentleman of Scotland, the thought of employing some such agent for igniting the gunpowder of a loaded gun. After several experiments, he took to London, in 1806, a fowling-piece having a lock, in which a small piece of apparatus struck smartly against a morsel of fulminating mercury, exploded it, and caused the ignition of the gunpowder. The principle was established, though the details were still imperfect; and Mr. Fordyce was encouraged by the then Master-General of the Ordnance to make further experiments, which he did. Fordyce proposed, as his reward, to be paid the price of the gunpowder which would be saved by the government in two years; but changes of administration, and difficulties of various kinds, interfered with the hoped-for progress of the method; and it was not till many years afterwards that its use became at all extensive in England, or indeed anywhere.

When however it became known that a slight blow would explode certain powders, and that this explosion would ignite gunpowder, numerous improvements became introduced by degrees. Various salts and chemical compounds, such as some of the chlorates, nitrates, and fulminates, will explode in this way; the most familiar example of which is afforded by the "lucifers" or "congreves" now sold so cheaply in the streets, and which ignite so readily by friction (in effect a series of minute percussions). About thirty years ago Dr. Ure conducted a series of experiments for the Board of Ordnance on certain points connected with these detonating compounds; such as the best proportion in the ingredients for fulminating mercury and other varieties; the best mode of preparation; the mode in which gases produced by the explosion affect the iron- and brass-work of a gun; the degree to which moisture or damp injures the mixtures; the effect of difference of climate on them; the best mode of protecting them from injury; and the probable effect of the gases (resulting from the explosion) on the health of a close mass of men in an army. Dr. Ure gives the results of the experiments in his 'Dictionary,' in the course of which he states that the French prepare forty thousand percussion charges from two pounds and a half of fulminating mercury.

When the method was first introduced, there was some difficulty in causing the explosion of the mixture to ignite the gunpowder. But this is now effected by putting the detonating mixture into a little copper box or cell called a *cap*, which is adjusted over the touch-hole, and so arranged as to the other part of the lock, that a smart blow striking the cap explodes its contents: the little cell itself is destroyed, so that a new one is required for each firing. The size of the cell, or "percussion-cap," the nature of the mixture, the quantity employed with each charge, and the mechanism for firing it, have been the subjects of many improvements, some of which were patented. The caps are made in large numbers at Birmingham, in much the same manner as metal buttons; blanks being cut out of sheet copper or mixed metal, and stamped or pressed into the proper shape.

Many contrivances have also been suggested for applying these caps under a modified form to larger guns. Thus, Commander Henderson, in 1838, contrived a means whereby a ship's armourer could adapt percussion caps to the common guns of a ship. The cap is applied to the touchhole, covered with an iron cap, and exploded with a slight blow from a mallet.

The detonating compound, with or without the small containing copper cap, has been applied to several varieties of shells to be fired from mortars, and to explode only when the shell strikes against the object against which it is directed. In ordinary circumstances a bomb-shell, or similar missile, has a fuse so attached to it as to ignite the gunpowder within after a certain space of time; but the object of the detonating shells is to dispense with such a fuse. Colonel Maceroni, in 1826, proposed the use of shells in which a short tube was screwed into one side of the shell, and a percussion-cap placed in the tube, just

before the shell was to be fired from the mortar: the striking of the shell against any solid object exploded the compound, ignited the gunpowder, and burst the shell.

Many other such shells have been from time to time proposed, of which those by Captain Norton were a good deal noticed in the public prints about sixteen years ago; the experiments at Woolwich, in 1842, with these shells, were made with the view of determining whether the shell would be *certain* to explode in striking the object.

Percussion caps have now for some years been adopted universally in the armies of Europe. For the English army they are manufactured at Woolwich. The following are the various operations:—

- 1st. Copper is cut into sheets 24 in. long and 3½ in. wide.
- 2nd. Each slip is smoothed and brought to its proper dimensions by being passed between rollers.
- 3rd. Crosses ¾ in. in diameter are cut out of the slips.
- 4th. The crosses are put into iron cylinders lined with copper and made red hot. After remaining in this state for some time they are plunged into cold water to anneal them.
- 5th. After being pickled in dilute sulphuric acid to remove the oxide.
- 6th. They are dried by being shaken in a bag of dried sawdust.
- 7th. They are then oiled in a drum.
- 8th. The crosses are then put under a die, which punches them into the shape of a cap, making the government mark at the same time. These caps differ from the ordinary caps in having a rim like the brim of a hat, in order to be more easily handled.
- 9th. They are then cleansed from oil in a bag of sawdust.
- 10th. They are then arranged by shaking into the holes of a brass plate, which contains 1000, for the purpose of charging.
- 11th. The plate containing 1000 caps is then placed in the charging machine to be loaded with a composition, consisting of fulminating mercury, chlorate of potash, and ground green glass.
- 12th. The composition is pressed in by a machine having points fitting into the caps.
- 13th. The composition which has been pressed into the caps receives a coating of varnish from a frame, to which are affixed a number of small nipples corresponding to the caps, which being dipped into the varnish carry the varnish into them.
- 14th. The varnish in the caps having been hardened in a steam bath.
- 15th. The varnish is glazed by polishing each separately in a lathe with a projecting nipple which fits into the cap.
- 16th. The caps being again shaken in a bag with fine sawdust are fit for use.

They are then packed in parcels of 25 each, which accompany the packages of 20 cartridges.

CAPSICINE is an alkaloid found in the capsules of *Capsicum annuum* and other species of *Capsicum*, which are used in the manufacture of cayenne pepper. It has a burning taste, and may be crystallised. It is insoluble in water and ether, soluble in alcohol. It forms crystallisable salts with sulphuric, nitric, and acetic acids. Its composition is unknown.

CA'PSICUM or bird-pepper, a genus of solanaceous plants, of which the botanical account has been given in the NAT. HIST. DIV.

The fruit or pod of several species of capsicum is used in different parts of the world, and under different names, as a stimulating condiment with food, or externally as a rubefacient, or internally as a powerful excitant to the nerves of the part with which it comes in contact. The *C. annuum*, or Spanish pepper, the *C. frutescens*, or Chillies, called also Cayenne pepper, and the *C. baccatum*, or bird-pepper, are chiefly employed. They are natives of the East and West Indies, South America, &c., and are of great utility, along with different articles of food, in rousing the energies of the stomach when impaired by the heat of the climate, and thereby assisting digestion. Even birds have recourse to the seeds, and many parrots and other birds die during their voyage or soon after they reach Europe for want of this natural stimulant. The pods contain two distinct principles: the one capsaicin, an alkaloid, which is the acrid principle; the other an ethereal oil, which is the stimulating principle: it resides chiefly in the external layers of the fruit and in the seeds.

The bruised pods, or Cayenne pepper, may be employed in the form of a cataplasm as a powerful rubefacient, which in many cases is preferable to common sinapisms. It is also of great service as a gargle, either alone or in conjunction with cinchona and serpentaria in the sore throat, when threatening to run into a state of mortification, or scarlatina maligna. It may also be given internally with the same adjuncts in the same disease. In fevers, both typhoid and intermittent, it is often a useful accompaniment to Peruvian bark; and in many cases of dropsy from debility, along with iron it is of great benefit. But it is in dyspepsia, dependent upon atony of the stomach, that it is most serviceable. Vinegar which has acquired its virtues (Chili vinegar) is the most suitable accompaniment to all kinds of fish at dinner. One grain of Cayenne pepper, with four grains of blue pill, is one of the most useful of all preventive agents against cholera. Such a pill, taken every night for three or four nights at bed-time, is invaluable.

CAPSTAN. [WINDLASS.]

CAPSULES. This name is given to two kinds of manufactured articles, having very little relation one to another; the one being as a covering for the corks of bottles, the other as a receptacle for medicines.

In 1842, and again in 1849, Messrs. Betts took out patents for the manufacture of metallic capsules, to cover the corked mouths of bottles and jars. Before that time, such articles had usually been made wholly of tinfoil; but the patentees devised a mode of coating lead with tin, which would enable them to prepare the capsules at a cheaper price. They placed a tin-plate on a thicker lead-plate, united them, and rolled them to the required thickness. For some purposes they coated the lead on both sides with tin, producing a brilliant white ribbon, containing nine times as much lead as tin, and capable of resisting acids. The ribbons, whether singly or doubly coated, were cut into discs, and made into capsules. The manufacture entailed a loss at first, but brought in great profit afterwards. One pickle-merchant was accustomed to use these capsules to the value of 250*l.* a month. The prepared metal itself, under the name of Betts's metal, was used for other purposes besides capsules. The extent of the trade in these small articles was illustrated in two or three ways before the law-courts. In 1856, the patentees applied for an extension of the patent of 1842, on the plea that the early years of its exercise had been unsuccessful; but this was refused, on the ground that there was no special merit in the invention, and that a profit of 20,000*l.* had already been made out of it. About the same time, these capsules became the subject of a chancery-suit between the four brothers Betts, which ended in an award of the property in the capsules to one brother, and sums of money to the other three. A patent trial also occupied one of the Courts, to decide whether certain patents taken out in 1804 and 1820 were of such a kind as to invalidate Betts' patent: another example of the high mercantile value often attached to articles comparatively insignificant.

The capsules which belong to medicine, rather than to manufactures, are sweetened envelopes for nauseous or repulsive medicines. They are generally made of gelatine and sugar, sometimes with a little gum. The mode of producing and filling them is curious. The bulbous end of a metal rod is oiled, and dipped into a strong solution of sweetened gelatine; the rod is whirled round a few times, to diffuse the gelatine over the surface of the bulb; the little gelatine globes are removed when sufficiently dry, placed on large-headed pins to harden, and the pins stuck into a piece of cork. When dry, each little globe or capsule is filled with the liquid medicine by means of a small tube, and the orifice is finally closed with melted gelatine. Some of the capsules are made of gut or fine membrane, shaped by being stretched over an oiled bulb of glass. The medicines administered in capsules are such as balsam of copaiba, castor oil, cod-liver oil, &c.

CAPTAIN (from the French *capitaine*, which comes from the Latin *caput*, a head), in the naval service, is an officer having the government of a ship of war; and, in the army, is one who commands a troop of cavalry or a company of infantry.

In military affairs, the title of captain seems to have been originally applied, both in France and England, like that of General at present, to officers who were placed at the head of armies or of their principal divisions, or to the governors of fortified places. Père Daniel relates that it was at one time given to every military man of noble birth; and adds that, in the sense in which it is at present used, it originated when the French kings gave commissions to certain nobles to raise companies of men, in proof of which he quotes an ordonnance of Charles V. This must have been before 1380, in which year that king died. In the English service the denomination of captain, in the same sense, appears to have been introduced about the reign of Henry VII., when it was borne by the officers commanding the yeomen of the guard, and the band of gentlemen pensioners. (Grose's 'Military Antiquities,' vol. i.)

The established price of a captain's commission is, in the Life Guards, 3500*l.*; in the Dragoons, 3225*l.*; in the Foot Guards, with the rank of lieutenant-colonel, 4800*l.*; in the infantry of the line, 1800*l.*; and no officer can be promoted to the rank of captain until he has been two years an effective subaltern. The full pay of a captain in the Life and Foot Guards is 15*s.* per day; in the Dragoons, 14*s.* 7*d.*; and in the infantry of the line is 11*s.* 7*d.* per day.

The duty of a captain in the army is one of considerable importance, since that officer is responsible for the efficiency of his company in every qualification by which it is rendered fit for service: he has to attend all parades; to see that the clothing, arms, &c., of the men are in good order, and that their pay and allowances are duly supplied. When the army is encamped, one captain of each regiment is appointed as captain for the day; his duty is to superintend the camp of his regiment, to attend the parading of the regimental guards, to visit the hospital, to cause the roll to be called frequently and at uncertain hours, and to report everything extraordinary to the commanding officer.

A high degree of responsibility rests upon the commander of a ship of war, since to him is committed the care of a numerous crew, with whom he has to encounter the dangers of the ocean and the chances of battle; and as the floating fortress, with its costly artillery and stores, when transferred to the enemy, increases by so much his naval strength, it is evident that nothing but utter inability to prevent him from getting possession can justify the commander in surrendering. In the old French service the captain was prohibited from abandoning his ship under pain of death; and in action he was bound under the same penalty to defend it to the last extremity: he was even to blow up his ship rather than suffer it to fall into the enemy's power.

The pay of a captain in the navy varies with the rate of the ship, from 61*l.* 7*s.* per month for a first-rate, to 26*l.* 17*s.* for a sixth-rate. Commanders of sloops have 23*l.*, and a captain of marines 14*l.* 14*s.* per month.

From the book of general regulations and orders, it appears that lieutenants of her majesty's ships rank with captains of the army. Commanders (by courtesy entitled captains) rank with majors. Captains (formerly designated post-captains) with lieutenant-colonels; but after three years from the dates of their commissions they rank with full colonels.

The rank of post-captain was that at which when the commander of a ship of war had arrived, his subsequent promotion to a *flag* took place only in consequence of seniority, as colonels of the army obtain promotion to the rank of general officers. Such captain was then said to be *posted*; but this title does not now exist.

Several petty officers in a ship bear the title of captains: thus there is a captain of the fore-castle, a captain of the hold, captains of the main- and fore-tops, of the mast, and of the after-guard.

CAPUCHINS. [FRANCISCANS.]

CAR, IRISH. [STAGE CARRIAGES.]

CARABINE. [ARMS.]

CARAMEL ($C_{12}H_{20}O_6$) is a name given to cane-sugar when it has been exposed to a temperature of 420°. The sugar loses three equivalents of water, and becomes converted into a brown mass. It is used as a colouring matter by cooks and confectioners, and is also employed for colouring spirits.

CARAPINE, an alkaloid found in the *Carapus guianensis*. It forms crystallisable salts with hydrochloric and acetic acids. Its composition is not known.

CARAT, KARAT. The karatium (*κερατιον*?) was originally the twenty-fourth part of the *marc*, or half-pound, among the French, from whom the word came: so that three carats made an ounce. Eisen-schmidt cites a coin of Charles VII., of an ounce weight, bearing the legend—

"D'or fin suis, extrait de ducats
Et fus fait pesant trois karats."

The carat was a small weight used for gold and jewels, and (Pau-ton) varied greatly in different countries. But at last it went out of use, except only in the sense in which it still exists, namely, that a carat means the twenty-fourth part of any weight of gold or gold alloy. If such a weight be all gold, it is said to be twenty-four carats fine; if one-third only be gold, it is said to be eight carats fine.

The karath occurs (Ducange) in an old English charter as a measure of wine; but this is the *carrada* or *carrata* formerly used as a measure of liquids, and supposed to be the quantity which could be carried in a *carrus* or car.

The carat is also used in the weighing of diamonds, and is equal to 3½ grains troy.

CARAVAN, a travelling body of merchants or pilgrims, who join company for safety and convenience. The term, which is of Persian origin (*Kārvān* in Persian having the same signification as Caravan in English), is applied to journeys in the East, more particularly to those made in Arabia, Nubia, Syria, Persia, and Asia Minor; but the practice obtains, though mostly on a smaller scale, in many other countries.

In the East the caravans have a commercial or religious character, and very frequently both; the greatest of them all, or those which proceed annually to the holy city of Mecca, have always trade as well as prayers in view. These caravans are regularly organised by government, and placed under the direction of officers of high rank, who assign to the different travellers their proper place in the long line of march, and see that good order is maintained. Sixty thousand men and twenty thousand camels have sometimes arrived at Mecca with the Hadji or pilgrim caravans. But this amount is insignificant, compared with the numbers that flocked to the holy city in other ages. The Syrian caravan, as it is called, though it first starts from Turkey, is now the most numerous and the best regulated. This caravan sets out from Constantinople, or rather from the Asiatic suburb Scutari, and collects pilgrims and traders all through Anatolia and Syria. On arriving at Damascus, the caravan is under the protection of the Pasha of Damascus, who derives both honour and profit from the charge. At this pleasant city it generally remains three or four weeks, in order to prepare for a journey of thirty days across the desert. Here also the camels are changed, the Anatolian camel not being considered fit for such a journey. When all is ready, the Pasha of Damascus, or one of his chief officers, puts himself at the head of the caravan, which he accompanies to Mecca. The signal for encamping and starting is the firing of a musket. On its route across the desert, where marauding Arabs are always on the look out, a troop of horse rides in front, and another in the rear to bring up the stragglers. The different parties of travellers, who are distinguished by their provinces or towns, keep close together, and each party knows its proper station. The usual arrangement of the hadjis is to contract with a mekowem, a man who speculates in the furnishing of animals and provisions, has his camels, tents, servants, meat, coffee, &c., and who takes upon himself all the trouble and expense for a given sum.

The Egyptian pilgrim caravan, which starts from Cairo, is regulated

in much the same manner; but it is not so large, and its route, by the head of the Red Sea and through a country where fierce Bedouin Arabs are plentiful, and wells of water very scarce, is much more dangerous.

The Persian caravan to Mecca, which used to come by Bagdad through Mesopotamia and Syria, and the Moggrebin (or Moorish) caravan, which, starting from Morocco, used to travel all through Northern Africa, have both become very irregular, though many Persians, Moors, and negroes find their way to Jidda, the port of Mecca, by sea. Considerable troops of Mohammedan Indians also visit Mecca. The great Indian caravan, which started from Muscat and travelled by Nejd to Mecca, has long been given up.

When the caravans arrive at Mecca, bringing with them goods from so many parts of the world, that city presents the appearance of a vast fair. In former times there was a second great pilgrimage and fair at Medina. This is frequently divided into two portions, the 'tayyarah,' or flying caravan, and the 'rakh'; but even in this each person only carries his own saddle-bags.

Besides these large annual caravans, others on a smaller scale are constantly occurring in the East, where merchants and travellers going the same road wait for one another until they can form a caravan, when they generally appoint one of their voluntary association to regulate the order of march. A recent writer, visiting Ararat, says that in the neighbourhood of that mountain he saw the halt of one of those caravans which traverse Armenia in the way to and from Persia; that its encampment occupied several miles in extent, that nearly three thousand horses were scattered over the plain, and that the carriers and travellers amounted to seven or eight hundred. He adds, that the horses were carefully tended, and that the evolutions of the train were performed without noise and with much regularity.

The *caravan-sarais*, or halting-places for the caravans, are generally plain four-sided buildings, with an inner open court, around which are one or two rows of totally unfurnished apartments for the use of travellers, who are expected to bring with them all they need. They, in fact, only afford some protection for the cattle and goods against marauders, and usually furnish a supply of water. They are commonly situated in the wildest and most desolate places, and the institution and support of them is deemed highly meritorious by all devout Mohammedans.

But the caravan trade is not limited to Southern Asia. The great trade between China and Russia is a caravan trade. The road runs from Peking through the great wall to Chalgan, where the goods are taken from horses and put upon camels, which are kept and let out for this purpose by the Kalka-Mongols. From Chalgan the route lies through part of the desert of Kobi to Kiachta, the great border-market for the barter of Chinese and European articles: the journey is from 70 to 90 days. Other similar lines of route exist in Russia and the countries to the east of the Caspian Sea. All the trade with the interior of Africa is also carried on by means of caravans, though they are there especially known as *CAFFILAS*. They are composed of camels and asses; and Captain R. F. Burton has given an account of them in his 'First Footsteps in East Africa,' 1856; as also of those of Asia, in his 'Pilgrimage to El Medinah and Meccah,' 1856.

Among the knights of Malta, in whose history it is continually used, the word caravan had a very different meaning. It signified a troop or corps of knights appointed by the Order to serve in any garrison, and also the crew or the cruise of any of their galleys against the Turks; for such cruises were called caravans, and every knight was bound by the laws of his society to make so many *caravans*, or, in other words, so many sea-voyages.

CARAWAY, OIL OF. The essential oil of caraway is obtained by distilling the crushed seeds of the *Carum Carui*. About five per cent. of the oil is obtained. At first the oil is of a pale yellow colour, but it subsequently becomes brownish; it possesses a penetrating aromatic odour and taste, and an acid re-action. Its sp. gr. is .938, and it boils at 401°. It appears to contain two hydrocarbons, one analogous to CYMEN, and the other to CUMINOL. Distilled with caustic potash it yields *caruen*, or *carvene* ($C_{10}H_8$), and the residue contains an acrid oil, to which the name *caruacrol*, or *carvole* ($C_{40}H_{28}O_3$), has been given.

Oil of caraway is employed as a flavouring agent, and in medicine. A solution of it in spirit is drunk in Germany, under the name of *Kümmelwasser*.

CARAWAYS, the ripe fruit of *Carum Carui*, an umbelliferous, European plant, of annual or biennial duration, with finely-divided aromatic leaves, white small flowers, and a fusiform root, not unlike that of a small parsnip. The seeds, as they are vulgarly called, are the furrowed halves of the ripe fruit, have a peculiar aromatic flavour, and are used as an agreeable carminative by confectioners; the roots themselves are eaten in the north of Europe.

Caraways are used in medicine as a carminative, and more extensively by the confectioners, and by the brewers' druggists to give flavour to the beer. The chief English cultivation of the plant is in Essex and Suffolk, upon old grass land broken up for the purpose. As it is a biennial, it is generally sown with another plant of the same tribe called coriander; and sometimes a crop of teasles is raised on the same land; the three give a very valuable return during two or three years.

Arthur Young, in his 'Agricultural Survey of Essex,' describes this

mode of cultivation minutely. Some old pasture land is ploughed up in spring; if the soil is a strong rich clay so much the better. Ten pounds of caraway seed, ten pounds of coriander, and twelve pounds of teasle seed are sown together on the newly turned-up soil, and harrowed in. As the plants appear they are carefully freed from all weeds, by repeatedly hoeing the land. The coriander is fit to be cut in July, and is threshed out on a cloth in the field. The produce is sometimes twenty cwt., worth on an average 16s. per cwt. The next year the caraway is reaped about the same time, and produces from 3 to 20 cwt., worth 30s. per cwt. In the autumn of the same year the teasles are fit to be cut. The produce of these is very various; sometimes worth 12*l.*, at other times only a quarter of that amount. The land, which would have been too rich for corn when first broken up, is now reduced to a moderate state of fertility. From this it is evident that it is only under peculiar circumstances that this profitable cultivation can be adopted.

CARBAMIC ACID ($C_2H_5NO_4$). When dry carbonic acid gas (CO_2) and dry ammoniacal gas (NH_3) are brought into contact, a white solid substance results. This has been called anhydrous carbonate of ammonia, but as it differs from that salt in all its more important characters it is now always classed with the amidated acid compounds produced by the re-action of dry ammoniacal gas on acid anhydrides, and is called *carbamate of ammonia*. It may be viewed as carbamic acid in which an equivalent of hydrogen is replaced by ammonium (NH_4). Thus—

Carbamic acid, it will be perceived, is derived from one equivalent of dry ammoniacal gas and two equivalents of carbonic acid; an equivalent of hydrogen of the former and an equivalent of oxygen of the latter uniting to form water.

Carbamate of ammonia possesses a strong ammoniacal odour, is very alkaline, and volatilises at 140° Fahr. Its vapour density is equal to 0.9. Anhydrous sulphuric acid converts it into sulphamate of ammonia, with disengagement of carbonic acid. Heated with sulphurous acid it gives an orange sublimate. Hydrochloric acid converts it, with the aid of heat, into carbonic acid and chloride of ammonium. It is very soluble in water, and is then rapidly converted into neutral carbonate of ammonia. When, however, carbonic acid is passed into solution of ammonia, carbonate of ammonia is not formed till after some time, or when the liquid is boiled. It is important to bear this in mind in the estimation of the carbonic acid in a mineral water, by means of an ammoniacal solution of chloride of calcium, as otherwise an error may occur.

Carbamate of methyl ($C_4H_5NO_4$, or $\text{NH}_2(\text{CO})_2\text{O} \} \text{C}_2\text{H}_5\text{O} \}$) (*urethylane*).

One of the several methods of producing this substance is to pass chloride of cyanogen into wood spirit containing a little water. When the latter is saturated it has a strong acid re-action, much ammoniacal salt is deposited, which should be removed and the liquid distilled. When the temperature has risen to about 280° Fahr., the receiver should be changed, and all that passes over between that degree and about 360° Fahr. collected and set aside. After a day or two it deposits crystals of carbamate of methyl, which after strong pressure are usually quite pure. In this re-action other matters are produced, but the principal decomposition is expressed in the following equation:—

Carbamate of methyl crystallises in elongated tabular plates. They are not deliquescent. Melting-point, when perfectly dry, 125.6° Fahr.; boiling-point, 350° Fahr.; vapour density equal to 2.62: very soluble in water and alcohol, less so in ether. Dilute sulphuric acid decomposes it into carbonic acid, methylic alcohol, and sulphate of ammonia; potash does the same, strong sulphuric acid blackens it, sulphurous acid and an inflammable gas being evolved.

Carbamate of ethyl $C_6H_7NO_4$, or $\text{NH}_2(\text{CO})_2\text{O} \} \text{C}_2\text{H}_5\text{O} \}$ (*urethane*). Ordinary spirit of wine is saturated with chloride of cyanogen, and the mixture heated over a water-bath in a flask with a long neck. Among other re-actions the following takes place:—

The resulting liquid poured off from an ammoniacal salt that deposits is submitted to distillation; ether, alcohol, and carbonic ether pass over, and finally leaf-like crystals of carbamate of ethyl are obtained.

This substance may also be produced by the re-action of ammonia on the carbonate or chlorocarbonate of ethyl. It is white, fusible at 212° Fahr., and distils when quite dry at about 356° Fahr., but if at all moist, decomposition occurs, and torrents of ammoniacal gas are

evolved. It is soluble in hot or cold water, alcohol, or ether; the solution is quite neutral, and does not precipitate soluble salts of silver. Its vapour-density is equal to 3.14.

Carbamate of butyl ($\text{C}_{10}\text{H}_{11}\text{NO}_4$, or $\text{NH}_2(\text{CO})_2\text{O}$ $\left\{ \begin{smallmatrix} \text{C}_4\text{H}_9 \\ \text{O} \end{smallmatrix} \right\}$) (*butyl-urethane*) is produced from butylic alcohol in a somewhat similar manner to the two previously-mentioned substances. Its boiling-point is about 430° Fahr. It crystallises in very beautiful pearly spangles, which are insoluble in water, but soluble in alcohol or ether.

Carbamate of amyl ($\text{C}_{12}\text{H}_{15}\text{NO}_4$, or $\text{NH}_2(\text{CO})_2\text{O}$ $\left\{ \begin{smallmatrix} \text{C}_5\text{H}_{11} \\ \text{O} \end{smallmatrix} \right\}$) (*amylurethane*) may also be obtained by the same method from amylic alcohol. It crystallises from boiling water in fine silky needles, which melt at 150° Fahr., and distil without alteration at 428° Fahr.

Sulphocarbamic acid ($\text{C}_2\text{H}_3\text{NS}_4$, or $\text{NH}_2(\text{CS})_2\text{S}$ $\left\{ \begin{smallmatrix} \text{H} \\ \text{S} \end{smallmatrix} \right\}$) is a nearly colourless, or slightly reddish-coloured oily body, produced by decomposing sulphocarbamate of ammonia with dilute sulphuric or hydrochloric acid. It is heavier than water, and possesses a peculiar odour somewhat resembling sulphuretted hydrogen. It decomposes carbonates with effervescence. It is not very stable, soon decomposing into cyanic acid, hydrosulphocyanic acid, and other products.

Sulphocarbamate of ammonia ($\text{NH}_2(\text{CS})_2\text{S}$ $\left\{ \begin{smallmatrix} \text{NH}_4 \\ \text{S} \end{smallmatrix} \right\}$) is obtained by digesting together, in a hermetically sealed tube, at a temperature of 60° Fahr., a mixture of one volume of absolute alcohol saturated with ammoniacal gas and a solution of 0.16 of a volume of bisulphide of carbon (CS_2), or sulphocarbamic acid in 0.4 of a volume of alcohol. Other substances are at the same time produced.

The sulphocarbamate of ammonia crystallises in long prisms of a lemon-yellow colour, and has an odour resembling sulphide of ammonium. Heated with caustic potash it is decomposed into sulphocyanide and sulphide of potassium, water and ammonia.

Metallic sulphocarbamates are produced in most cases when a soluble salt of a metal is added to an alkaline sulphocarbamate. Thus:—

The lead and zinc salts are white, the copper salt yellow. The nickel salt precipitated in a similar manner is yellow-green, the mercuric salt white, the platinum salt yellow-brown. Lime and baryta salts yield no precipitate.

When sulphocarbamate of ammonia is dissolved in five or six parts of water and aqueous solution of chlorine gradually added, the mixture being well shaken on each addition, white crystalline flocks precipitate. These, purified by washing with water, constitute *hydranzothine*, the decomposition by which they are produced and their composition being thus expressed:—

This body is the *bisulphide of sulphocarbammmonium*, or simply bisulphide of ammonium, in which two equivalents of hydrogen are replaced by two equivalents of (CS). It is almost colourless and without odour when recently prepared; slightly soluble in water, more so in alcohol and ether.

Sulphocarbamate of ethyl, $\text{NH}_2(\text{CO})_2\text{S}$ $\left\{ \begin{smallmatrix} \text{C}_2\text{H}_5 \\ \text{S} \end{smallmatrix} \right\}$ *sulphourethane xanthogenamide*, is produced by the re-action of xanthic ether (disulphocarbonate of ethyl) and ammonia. It is only slightly soluble in water, but very much so in alcohol or ether. By spontaneous evaporation it is obtained in beautiful rhomboidal prisms or octohedra, sometimes very large: heated they melt at about 97° Fahr., and at a higher temperature decompose. Xanthogenamide combines with certain metallic salts, producing crystalline compounds. Nitric acid converts it into a substance that crystallises in prisms; it has been called *oxysulphocyanate of ethyl*.

Sulphocarbamate of amyl, $\text{NH}_2(\text{CO})_2\text{S}$ $\left\{ \begin{smallmatrix} \text{C}_5\text{H}_{11} \\ \text{S} \end{smallmatrix} \right\}$ *xanthamylamide*, is an oily body, neutral to test paper, insoluble in water, soluble in alcohol or ether.

Methyl-carbamic acid ($\text{NH}(\text{C}_2\text{H}_5)(\text{CO})_2\text{O}$ $\left\{ \begin{smallmatrix} \text{H} \\ \text{O} \end{smallmatrix} \right\}$) and

Ethyl-carbamic acid ($\text{NH}(\text{C}_4\text{H}_9)(\text{CO})_2\text{O}$ $\left\{ \begin{smallmatrix} \text{H} \\ \text{O} \end{smallmatrix} \right\}$). The two compounds

known as *anhydrous carbonate of methylamine* and *anhydrous carbonate of ethylamine* are combinations of the above acids with methylamine and ethylamine respectively.

Ethyl carbamate of ethyl, $\text{NH}(\text{C}_4\text{H}_9)(\text{CO})_2\text{O}$ $\left\{ \begin{smallmatrix} \text{C}_2\text{H}_5 \\ \text{O} \end{smallmatrix} \right\}$ *ethylurethane*, is a slightly oleaginous liquid, obtained by the re-action of cyanate of ethyl on alcohol. Boiling point, 345° Fahr.; specific gravity, 0.986; vapour density, 4.071.

Phenyl-carbamic acid, $\text{NH}(\text{C}_6\text{H}_5)(\text{CO})_2\text{O}$ $\left\{ \begin{smallmatrix} \text{H} \\ \text{O} \end{smallmatrix} \right\}$ *carbanilic acid*, (or

anthranilic acid), has been obtained by Fritzsche, by acting on indigo with caustic potash. It crystallises in colourless prisms, brilliant, large, and transparent. It unites with metals, forming crystalline salts.

Phenyl-carbamate of methyl, $\text{NH}(\text{C}_6\text{H}_5)(\text{CO})_2\text{O}$ $\left\{ \begin{smallmatrix} \text{C}_2\text{H}_5 \\ \text{O} \end{smallmatrix} \right\}$ *carbanimethyllane*, an oily compound, heavier than water; obtained by treating sulphide of ammonium with nitrobenzoate of methyl.

Phenyl-carbamate of ethyl, $\text{NH}(\text{C}_6\text{H}_5)(\text{CO})_2\text{O}$ $\left\{ \begin{smallmatrix} \text{C}_4\text{H}_9 \\ \text{O} \end{smallmatrix} \right\}$ is a body very similar to the above methyl-compound. Ammonia converts it into phenyl-urea and alcohol.

CARBAMIDE (CONH_2). This substance is produced by the action of chloro-carbonic acid gas on ammonia. Sal-ammoniac is also formed at the same time. Under the influence of the mineral acids, carbamide yields ammonia and carbonic acid. According to the recent experiments of Natanson, carbamide is identical with urea, and the above formula therefore requires to be doubled ($\text{C}_2\text{H}_4\text{N}_2\text{O}_2$). [UREA.]

CARBANILIC ACID. [CARBAMIC ACID: *Phenyl-carbamic Acid*.]

CARBANILIDE, or *Diphenylcarbamide* ($\text{C}_{12}\text{H}_{10}\text{N}_2\text{O}_2$). This substance is carbamide, in which two equivalents of hydrogen have been replaced by two of the radical phenyl (C_6H_5). It is prepared by passing chloro-carbonic acid gas into aniline. The re-action is thus expressed:

It is a white crystalline inodorous body, capable of being distilled without decomposition. It fuses at 401° F.

CARBAZOTIC ACID ($\text{C}_{12}\text{H}_3(\text{NO}_4)_3\text{O}_2$). This acid, which has also been called *picric acid*, *nitropicric acid*, *nitrophenic acid*, and *trinitrophenylic acid*, results from the action of nitric acid upon a great number of vegetable and animal substances. A large quantity is furnished by indigo: one part of this substance reduced to coarse powder is to be gently heated with eight or ten times its weight of moderately strong nitric acid. The indigo dissolves with the evolution of much nitric oxide gas. As soon as the effervescence is over, the liquor is to be boiled, and nitric acid added from time to time till the evolution of nitric oxide ceases: on cooling, crystals of carbazotic acid are obtained, which are of a brilliant yellow colour; they are to be washed with cold water, dissolved in boiling water, and re-crystallised. Carbazotic acid is however now made by acting upon carbolic acid with nitric acid.

The pure acid is said to crystallise in equilateral triangular laminae, the primary form being an octahedron with a rhombic base. It reddens litmus paper, and has a very bitter taste, and on this account it was long called *bitter of indigo*. When heated, it fuses and sublimes without decomposing. If it be rapidly heated in the air, it burns without explosion, leaving charcoal. This acid is but slightly soluble in cold water, but much more so in hot; the solution is of an intense yellow colour. Alcohol and ether dissolve it readily. Chlorine and iodine do not act upon this acid, even when it is fused in these substances. Heated with aqua regia it gives chloranile and chloropicrin. It contains no water, and is said to be poisonous.

The saline compounds of this acid are called *carbazotates* or *nitropicrates*. An account of them may be seen in Gerhardt's 'Traité de Chimie,' tome iii. p. 41.

Carbazotic acid is now extensively employed for dyeing silk and wool yellow. It is also said to be sometimes fraudulently substituted for hops in the manufacture of beer.

CARBETHYLIC ACID. [ETHYL, *Carbovinic Acid*.]

CARBIDE. [CARBURET.]

CARBOBENZOIC ACID, *Myroxyllic Acid*. An acid of problematical existence, obtained from *cinnamcin*. It is probably impure benzoic acid.

CARBOHYDROGEN. [HYDROCARBONS.]

CARBOLIC ACID = *Hydrated Oxide of Phenyle*, *Phenyl Alcohol* ($\text{C}_6\text{H}_5\text{O} + \text{HO}$) is one of the products of coal tar, and is found amongst those portions which boil between the temperature of 300° and 400°. It is procured by washing this peculiar product with twice its weight of potash ley. On the addition of an acid to this mixture, carbolic acid may be obtained in the form of a heavy oil. When pure it is a heavy transparent oil, refracting light very strongly, neutral to test paper, and having a specific gravity of 1.062 to 1.065. It has the taste and odour of creosote, which it much resembles. They are probably identical, or homologous.

CARBOMETHYLIC ACID. [METHYL.]

CARBON. This element and its combinations act an important part in the mineral constitution of our earth. Following the system of Berzelius, the substances containing it are arranged in three groups, the first consisting of the mineral forms of pure carbon, the second of the carbonates, and the third of those carboniferous masses in which the elements are combined according to the principles of organic chemistry, and which have resulted from vegetable matter.

The first group consists only of three essentially different varieties, namely, two crystallised and one amorphous variety of carbon. The crystallised varieties are known under the names of **DIAMOND** and

GRAPHITE [NAT. HIST. DIV.], whilst the amorphous kind is met with as mineral charcoal interspersed amongst coal and anthracite.

The second group, the carbonates, presents us with a numerous mineralogical family of the highest interest, both in a scientific and in an economical point of view. For the purpose of studying them with the greatest facility the carbonate of lime may be taken as a type, to which the whole family may be conveniently referred. This substance possesses the peculiarity of dimorphism; that is to say, it occurs in forms belonging to two different systems of crystallisation, namely, the rhombohedral and the prismatic, and is called, when its crystals belong to the former, CALCAREOUS SPAR, and when to the latter ARRAGONITE, under which terms they are described in NAT. HIST. DIV. The chemical composition of these minerals is that of a neutral salt, being one atom of carbonic acid united with one atom of the oxide of calcium, or lime, and therefore the chemical composition of both is denoted by the symbol CaO CO_2 . But the oxide of calcium is isomorphous with the similarly constituted oxides of magnesium, barium, strontium, iron, manganese, zinc, cerium, lead, and copper; and each of these oxides occurs combined with carbonic acid in the proportion of atom to atom, some of them producing crystals isomorphous with calc-spar, and others on the contrary with arragonite. But in addition to the mineral species produced by the combination of any one of these oxides with carbonic acid, an endless variety of isomorphous crystals is formed by the combination of two or more of the above carbonates, which are capable, according to the laws of isomorphism, of uniting in any proportion, as may be seen in the varieties of calc-spar, which are known as brown-spar, bitter-spar, dolomite, where portions of the oxide of calcium are constantly replaced by the oxides of magnesium, iron, and manganese. None of the carbonates of these oxides are found, however, like the carbonate of lime, to be dimorphous, and to occur crystallised both in the rhombohedral and the prismatic system; they may be divided therefore into two isomorphous groups, the one headed by calc-spar, and the other by arragonite; and it is only among the oxides of the same group that it is usual to find the one oxide substituted for the other.

The first group crystallised in the rhombohedral system consists of

Calc-spar	CaO CO_2
Magnesite or talc-spar	MgO CO_2
Manganese-spar	MnO CO_2
Iron-spar	FeO CO_2
Zinc-spar	ZnO CO_2
Bitter-spar	$\text{CaO CO}_2 + \text{MgO CO}_2$
Brown-spar	$(\text{CaO, MgO, MnO, FeO}) \text{CO}_2$

The second group crystallised in the prismatic system consists of

Arragonite	CaO CO_2
Strontianite	SrO CO_2
Witherite	BaO CO_2
White Lead	PbO CO_2

But although the minerals of these groups are classified together as being isomorphous, this word cannot be used in its strictest sense, and as denoting an exact identity of the angles of inclination between corresponding planes in the different species, as those when measured at the ordinary temperature are found to differ from each other by small but nevertheless very perceptible magnitudes. The following table of the angles in the terminal edges of the ground-forms of the principal species of the first group, and parallel to the faces of which the cleavage planes of each occur, will best show this difference. According to the most careful measurements the angles are:

For Calc-spar	$105^\circ 5'$
„ Bitter-spar	$106 15$
„ Manganese-spar	$106 51$
„ Iron-spar	$107 0$
„ Talc-spar	$107 25$
„ Zinc-spar	$107 40$

The three angles of calc-spar, bitter-spar, and talc-spar, when the chemical composition of these minerals is considered, present a very interesting and striking relation, the angle of bitter-spar being the arithmetical mean between those of the pure carbonates of lime and magnesia, while its chemical composition may be considered also as the mean of the other two, being composed of an atom of carbonate of lime united with an atom of carbonate of magnesia. That this is a particular instance of a more general law, that the increment of the angle in any compound over that of calc-spar is to the whole difference of the angles of the pure minerals, or $2^\circ 20'$, in the proportion of the number of atoms of carbonate of magnesia to the total number of atoms in the compound, appears to be established by the analysis and measurements of the French mineralogist, M. Beudant, who has made several experiments for the purpose of ascertaining this fact. An example will at once render this clear. Suppose on measuring the angle of a compound of carbonate of lime and magnesia we find it to be $105^\circ 40'$, which gives an increase over $105^\circ 5'$ equal to $\frac{1}{4}$ of $2^\circ 20'$; according to the experiments of Beudant we should be justified in concluding that the compound consisted of three atoms of carbonate of lime to one of carbonate of magnesia.

ARTS AND SCI. DIV. VOL. II.

In addition to the carbonates above mentioned, four others are known, namely, the native soda, Gay-Lussite, l'azure or blue copper, and malachite, which, although containing elements isomorphous with the former, are nevertheless differently crystallised, as they are of a different chemical composition, containing water of crystallisation.

The third class, all of which contain more or less evidence of their vegetable origin, are amorphous. They are all distinguished from other mineral bodies by their combustibility, the combustion being usually accompanied by flame. They may be divided into the four principal groups of coals, mineral resins, mineral oils, mineral pitches or bituminous bodies. The principal varieties are distinguished by and are described under the names of peat; coal and its varieties, brown coal, &c.; amber, honeystone, resinasphaltum, naphtha, petroleum, mineral pitch, asphaltum.

CARBON (C), a non-metallic elementary solid body, which is widely diffused throughout nature. The purest, and at the same time the rarest form in which it occurs is that of the diamond [DIAMOND, in NAT. HIST. DIV.]; the more common states in which it is met with are those of graphite [GRAPHITE, in NAT. HIST. DIV.] and mineral charcoal; but in these cases it is not free from admixture.

Another well-known form of carbon, but still impure, is the charcoal obtained from the decomposition of wood by heat.

The diamond differs so entirely in its obvious and physical properties from carbon in its more common states, that nothing less than the most decisive evidence of the identity of their chemical nature could have allowed of their being arranged together: the proof of their similarity is stated in the article CARBONIC ACID. In addition to these forms in which carbon occurs pure or in a free state, it is also met with in combination with other elements, in fact by far the largest amount of carbon is thus met with in combination. In combination with oxygen as carbonic acid, it occurs in the atmosphere, and dissolves in the waters of the ocean, rivers, springs, &c. In the same form, but further combined with lime and magnesia, it exists in enormous quantity in the earth's strata, as limestone, chalk, marble, dolomite, &c.; whilst combined chiefly with hydrogen, oxygen, and nitrogen, it enters largely into the composition of coal, peat, and lignite, as also of all animal and vegetable substances. From its invariable presence in organic substances it has been named the organic element.

Charcoal has already been mentioned as carbon procured from the decomposition of wood by burning. This operation is generally conducted in pits made in the ground; sometimes however it is carried on in iron cylinders. Wood is essentially composed of carbon, oxygen, and hydrogen; by the action of the heat it is decomposed, the oxygen and hydrogen are expelled, and uniting in certain proportions form water, and also with carbon various gaseous and other compounds are formed. Among the latter are acetic acid, sometimes called pyroligneous acid, and a peculiar inflammable fluid, known by the name of pyroxic spirit, and tar.

The remaining charcoal has the following properties: it is black, lighter than water, and full of pores, occasioned by the expulsion of the bodies volatilised. The heavier the wood from which the charcoal is obtained, the denser it is.

Charcoal, from whatever source procured, is absolutely infusible by any degree of heat however great; neither that of a mirror, the oxy-hydrogen blow-pipe, nor the voltaic discharge, being sufficient to produce fusion. In its common state it is one of the worst conductors of heat known, but its power is increased after being strongly heated. Charcoal is a conductor of electricity, which is so far from being the case with the diamond, that it may without insulation be rendered electrical by friction.

Charcoal is tasteless, inodorous, and insoluble in water. It possesses the property of destroying colouring matter, especially the charcoal procured by burning bones, which is usually called animal charcoal; it is largely used for this purpose in sugar-refining. [BONE BLACK.]

Charcoal, in common with other porous bodies, has the power of condensing gaseous bodies; but to a greater degree than most, or perhaps any other substances: graphite, on account of its compactness, does not possess this quality.

Saussure performed experiments to ascertain these facts by plunging a piece of red-hot charcoal under mercury, and introducing it when cool into the gas. He found that box-wood charcoal absorbed in 24 to 36 hours the annexed quantities of the following gases:—

Hydrogen	1.75 times its volume.
Nitrogen	7.5 „
Oxygen	9.25 „
Carbonic oxide	9.42 „
Olefiant gas	35 „
Carbonic acid	35 „
Nitrous oxide	40 „
Sulphuretted hydrogen	55 „
Sulphurous acid	65 „
Hydrochloric acid	85 „
Ammoniacal gas	90 „

These effects appear to depend entirely upon the mechanical action

R R

of the pores of the charcoal, for the gases are not at all absorbed in the ratio of their affinity for carbon, but generally according to the facility with which they are condensed; and thus it is that charcoal absorbs vapours more readily than gases, and liquids than either.

Dr. Stenhouse has recently shown that these effects of *deodorisation* and *disinfection* are due to the combustion of foetid and noxious substances which is effected within the pores of the charcoal at the expense of the oxygen which exists there in a highly condensed state. Dr. Stenhouse has successfully taken advantage of this valuable property, to construct respirators of charcoal for the purpose of preventing the access of noxious gaseous matters to the lungs, or conversely, in cases of foul breath to hinder the patient from tainting the atmosphere around him. The same chemist also proposes the employment of charcoal for purifying the atmosphere of hospitals, sick-rooms, &c.

Charcoal is highly combustible; it burns in the air when strongly heated, though not very rapidly; during this combustion carbonic acid is formed by the union of the oxygen of the air with carbon.

It has been mentioned that charcoal is not pure carbon, and when a quantity is burnt there always remains a portion of ashes, containing a considerable quantity of carbonate of potash and some other alkaline and earthy salts, which have been taken up from the soil in which the tree grew that furnished the charcoal.

Charcoal is used not merely for combustion, but also for the important purpose of making gunpowder. It is also applied to other various well-known uses. Carbon unites with all the elementary gases to form highly-curious and interesting bodies. Its inorganic compounds with oxygen are treated of under CARBONIC ACID and CARBONIC OXIDE; with chlorine, CHLORIDES OF CARBON; and with nitrogen, CYANOGEN. It combines also with sulphur to form bisulphuret of carbon, and it enters into the composition of several ternary compounds. Carbon enters into the constitution of all organic bodies, as will be seen from a reference to the formulæ of such bodies, which will be found described under their respective names.

CARBON, in an impure state, or charcoal, is employed medicinally, both internally and externally. Its power of absorbing gases and moisture renders it useful in some cases, while in other cases it seems to act by some power exerted on the vital energies of the system. A few grains of vegetable charcoal taken into the stomach cause a feeling of warmth and comfort in that organ, followed by a slight increase of the heat of the body generally. A considerably larger dose will occasion vomiting, and even diarrhoea. Charcoal, especially animal charcoal, possesses the power of destroying the colour, smell, and taste of a great variety of vegetable and animal substances, particularly of mucilages and oils, and of matters in which *extractive* abounds. Recently prepared charcoal, especially animal, has been recommended as an antidote in poisoning by aconite and other alkaloids. Allowed to remain in contact with valerian, galbanum, balsam of Peru, or musk, it destroys their characteristic odour and properties.

Meat and game, too far decomposed, may be restored to a condition fit for use by the employment of finely powdered charcoal, assisted by sulphuric acid. Water also may be restored from a tainted state by filtering it through charcoal. The interior of water-casks is charred in order to preserve the water in a pure state. Leeches, fish, &c., live better in water kept in charred vessels than in those of any other kind.

Charcoal, both from its antiseptic and vital properties, is useful in many forms of fever, especially the bilious, remittent, and intermittent fevers of warm climates, given during the interval of the vomiting of the black matter; and in yellow and typhoid fevers. It is also serviceable in dyspepsia, accompanied with fetid breath and eructations. It is sometimes of service in ulcerations of the tongue and fauces, connected with depraved digestion. It is likewise useful in obstinate constipation, given in doses of two or three dessert-spoonfuls every half-hour, or each hour, for a period of perhaps eighteen hours. In smaller doses it has been found useful in dysentery, where the motions are acrid and very offensive. Externally it is a beneficial application to foul ulcers, applied either in the form of fine powder, or as a cataplasm; but chloride of soda or lime are better applications. Persons who are troubled with excessive and strong-smelling perspirations of the feet find the inconvenience lessened by sprinkling the inside of their stockings with fine-powdered recently prepared charcoal. Finely powdered charcoal may also be employed as a styptic. Charcoal, especially that procured from the cocoanut, forms, along with either prepared chalk, rhatany-root, kino, or catechu, perhaps the best tooth-powder which can be employed when the gums are spongy and the breath fetid. A liniment of charcoal is sometimes useful in herpes, ringworm of the scalp, and other cutaneous diseases.

Animal charcoal, particularly that prepared from the flesh and bones of calves, given in the dose of a few grains, three or four times a day, is said to be very efficacious in removing chronic enlargements of the glands.

Carbonic acid gas, in a state of concentration, acts upon the human system as a powerful sedative poison. Unless largely diluted with atmospheric air, it cannot be breathed, as it stimulates the glottis, or entrance to the windpipe, to contraction, which causes the person

exposed to this gas to die of suffocation. But even when so far diluted as to be able to pass the glottis, and enter the lungs, it acts as a poison; and also when brought in contact with the skin (pure atmospheric air being breathed at the same time), or with the mucous membrane of the stomach. A variable quantity of carbonic acid gas exists at all times in the air, as essential to the respiration and the life of plants; but any considerable increase of this quantity is deleterious, and destructive to the life of both animals and vegetables, though plants will flourish in an atmosphere containing nine or ten per cent. of carbonic acid gas, provided they are exposed to the direct solar light, for this quantity is poisonous to them in the shade. (Saussure.) The cause of the absence of vegetation in the celebrated poison valley of Java is the existence of a subterranean source of carbonic acid gas, and not the shade of the upas-tree, as is popularly believed.

Carbonic acid gas is evolved from the combustion of fuel, especially charcoal, and during the process of fermentation; also from the coloured parts of the flowers of plants, both by night and day, and from the green parts of plants during the night; from the calcination of lime; and it is apt to be formed and accumulate in mines, particularly coal-mines, where it is termed *choke-damp*, and in old draw-wells, and in the famous *Grotto del Can*. It also is formed or extricated by the respiration of animals, and becomes the source of disease and death when many human beings are crowded together in close, ill-ventilated rooms.

When in such a state of concentration as not to pass the glottis, it produces instant suffocation, and if the person be not immediately removed from the obnoxious atmosphere, death ensues. But where it is diluted with atmospheric or other respirable air in sufficient quantity to be inhaled for a considerable time, symptoms closely resembling apoplexy are produced. This last casualty is most apt to occur from sleeping in a room with a charcoal fire, which has not a proper outlet for the gas, or in a green-house with plants, or even with a few flowers in a bedroom, above all from lime-kilns and brewers' vats.

When from any of these causes an individual has fallen into a state of stupor or insensibility, he is to be removed as speedily as possible into the pure fresh air, cold water should be dashed upon the face, ammonia may be rubbed upon the chest, and, if conveniences exist, he may be caused to breathe oxygen gas. Blood, but in moderate quantity, should be attempted to be procured from the arm or jugular vein, and efforts to effect this may be persevered in for hours with ultimate success.

Carbonic acid gas, diluted with a proper quantity of atmospheric air, has been advantageously employed, applied to limited portions of the body. Largely diluted, it has been recommended to be inhaled in the latter stages of phthisis pulmonalis, or consumption, to lessen the irritability, and remove the fetor of the breath arising from the morbid expectoration. It is in such cases merely a palliative. Children with whooping-cough are sometimes taken close to lime-kilns to breathe the carbonic acid gas—a very hazardous custom, as is also sleeping near lime-kilns for the warmth. When brought in contact with the mucous membrane of the stomach, it is often very serviceable; but if too strong, or its use is too long continued, it may give rise to alarming or unpleasant symptoms. The more speedy intoxication and headache which follow the use of the effervescing wines is due to the great quantity of carbonic acid gas which they contain. Even soda-water, if drunk in large quantity, may produce intoxication or headache.

The usual form of administering carbonic acid gas is either in some of the natural mineral waters, such as Seltzer, or by disengaging it from its combination with some alkaline base, such as carbonate of soda or potash: any acid given at the same time, by combining with the alkali, will liberate the gas. A vegetable acid, either the citric, in the state of lemon-juice, or tartaric acid, is commonly employed for this purpose; but in many instances sulphuric acid is preferable. Whenever great debility, or the phosphatic diathesis, as indicated by the state of the urine, exists, the use of a vegetable acid for the object above mentioned is prejudicial. (Prout, 'On Diseases of the Urinary Organs.')

The gas thus disengaged is of great utility in allaying irritability and spasmodic states of the stomach; thus it frequently checks vomiting, either simple, or even of blood.

In the irritable state of the kidneys and bladder which prevails in a phosphatic condition of the urine, water charged with a large portion of carbonic acid gas (but without any alkali) is of double utility, both from its sedative effect and its chemical properties of dissolving and holding suspended the phosphate of lime, and preventing it being deposited in the bladder. Externally water charged with carbonic acid gas has been employed as a wash or bath in many cutaneous diseases with good effect. The yeast poultice owes its soothing influence over irritable ulcers to the carbonic acid gas which is disengaged from it. A stream of carbonic acid gas has been proposed to be directed upon cancerous sores to allay the pain, and also upon burnt surfaces. But its employment in such cases requires caution.

CARBONATE, a salt composed of carbonic acid and a base. The carbonates are an important class of salts: some of them, as the carbonates of lime and magnesia, and the metallic carbonates, are

decomposed by heat; but the carbonates of potash and of soda do not suffer any alteration by exposure to it. For the various carbonates see the different alkaline, earthy, and metallic bases.

CARBONIC ACID (CO₂). There are two inorganic compounds of carbon and oxygen, namely, carbonic oxide, consisting of one equivalent of each of its elements, or six parts of carbon and eight of oxygen; and carbonic acid, formed of one equivalent of carbon and two equivalents of oxygen.

Carbonic acid was long known and observed to exist in various forms, and to be produced in different circumstances, before its nature was understood and its composition ascertained. Van Helmont recognised it as a peculiar matter, and called it *gas sylvestre*; Hales supposed it to be spoilt common air; Black gave it the name of *fixed air*, and made many curious and original experiments upon some of its compounds, showing that the causticity of the alkalies and lime depended upon its absence; Bergmann proved that it was an acid, and called it *aërial acid*; but Lavoisier first pointed out its true nature, and in consequence of his discovery it received the name of carbonic acid, which it still retains.

Carbonic acid exists largely in nature. It is in comparatively small quantity in the gaseous state in the atmosphere; it is in solution in most spring water, and in some called mineral waters to a considerable degree; but it is in solid combination that carbonic acid is found in the largest quantity, forming nearly 44-100ths of all limestones and marbles, besides occurring in less amount united with other earths and metallic oxides.

Carbon and oxygen do not appear to combine, or, if at all, very slowly at common temperatures, by direct action; but certain compounds which contain carbon, when undergoing the process of fermentation, yield a large quantity of carbonic acid. [FERMENTATION.]

It is also produced during the process of respiration; by animal and vegetable putrefaction; and by combustion, whether of oil, wax, tallow, vegetable matter, or coal.

Carbonic acid may be formed by the combustion of either charcoal or the diamond in oxygen gas; and it is found, that when 100 cubic inches of oxygen have combined with as much carbon or diamond as this quantity of gas is capable of taking up by combustion, there remains precisely as much in volume of carbonic acid gas as there was of oxygen employed. Thus 100 cubic inches of oxygen, weighing 34.4 grains, combine with 12.9 grains of carbon without any alteration of volume, and consequently 100 cubic inches of this gas weigh 47.3 grains, or its density is to that of atmospheric air as 1.526 to 1. By some chemists it is hypothetically regarded as composed of one volume of oxygen gas and one volume of the vapour of carbon, condensed into one volume. By weight it consists of

$$\begin{array}{rcl} 2 \text{ equivalents of oxygen} & = & 16 \\ 1 \text{ " carbon} & = & 6 \\ \hline \text{Equivalent} & = & 22 \end{array}$$

It contains twice as much oxygen as the bases which it saturates to form neutral carbonates.

When carbonic acid is required for experiment, it is usual to evolve it by decomposing a carbonate, rather than to form it by the combination of its elements as above described. For this purpose carbonate of lime, or chalk, or marble, may be put into a retort, and dilute hydrochloric acid being poured upon it, carbonic acid is plentifully given out; and although this gas is to a certain extent soluble in water, it may be received in jars filled with and inverted in water.

Carbonic acid gas is colourless and transparent, and therefore invisible; it has an acid and slightly astringent taste; it reddens litmus paper, but the blue colour returns as the acid volatilises. It extinguishes burning bodies, and is fatal to animals. On account of its great density, it diffuses slowly in the air, and hence it is apt to remain long in fermenting vats, old wells, &c., and has frequently produced fatal effects upon persons descending into them. Atmospheric air may however contain 1-20th of its volume of this gas, and be respired without becoming hurtful. On account of its great weight, it may be poured from vessel to vessel, as is shown by its extinguishing a taper repeatedly.

Carbonic acid, though gaseous at common temperatures and pressures, may be compressed into a liquid state, as shown by Mr. Faraday; and by the more recent experiments of M. Thilorier, it has been rendered even solid. Mr. Faraday's method of operating may be seen in the 'Phil. Trans.' for 1823. The liquid carbonic acid produced is limpid, colourless, extremely fluid, and refracts light less than water does. At 32° it requires a pressure of thirty-six atmospheres to retain it in a liquid state; in endeavours to open the tubes at one end, they always burst into fragments with a powerful explosion. M. Thilorier found that a jet of liquid carbonic acid received in a glass vial expanded to about 400 times its own volume, and by this produced so great a degree of cold, that one part of the carbonic acid congealed into a white powder, adhered to the glass, and retained its solidity for some minutes without pressure. Solid carbonic acid is now frequently made in large quantities by this process, and is employed for producing intense cold: by its aid mercury may be almost instantly frozen, even in

a red hot vessel. [FREEZING MIXTURES.] It has already been mentioned that carbonic acid gas is soluble in water, and various contrivances have been adopted for impregnating water and saline solutions with it, to imitate natural mineral waters. Among these, Dr. North's apparatus is well known, and is described in most works on chemistry. At the average temperature and pressure, water takes up its own volume of carbonic acid gas, and under a pressure of two atmospheres it dissolves twice its volume, and so on. The water thus impregnated becomes brisk and tart, and reddens litmus paper: when the water is boiled, the carbonic acid is expelled. Carbonic acid is detected by the properties of extinguishing flame, proving fatal to animals, reddening litmus paper, but not permanently, and giving a precipitate with lime water; this precipitate is carbonate of lime, which is re-dissolved by an excess of carbonic acid, and re-appears when that excess is expelled by heat.

Carbonic acid, though in small quantity, always exists in the atmosphere, as may be shown by exposing lime-water to the air; the proportion does not usually exceed about one 2000th of the volume of the air; it is produced by the processes of respiration, combustion, and animal and vegetable decomposition, as already alluded to.

CARBONIC ETHER. [ETHYL.]

CARBONIC OXIDE (CO), commonly called also oxide of carbon, was first obtained by Dr. Priestley, but its nature and composition were determined by Mr. Cruikshank. Carbonic oxide may be prepared in various modes: first, by direct action; if charcoal be made red-hot in a gun-barrel, and oxygen gas from bladders be repeatedly passed over it, the oxygen is converted into oxide of carbon. Dr. Priestley procured it by heating together chalk and iron filings; in this case the iron takes half the oxygen from the carbonic acid of the chalk, and thus from a compound of two equivalents of oxygen and one equivalent of carbon, the residual gas, which is carbonic oxide, is constituted of one equivalent of each element.

Another mode of obtaining it with great facility, is to heat oxalic acid in a retort with sulphuric acid. Oxalic acid is a compound of three equivalents of oxygen and two of carbon; by the action of the sulphuric acid it is separated into carbonic acid and carbonic oxide, which are both evolved in the gaseous state; if the mixed gases be then passed through a solution of potash, the acid, being soluble in this liquid, is dissolved, and the carbonic oxide remains nearly pure. The best mode of procuring carbonic oxide is to heat a mixture of one part of ferrocyanide of potassium and nine parts of concentrated sulphuric acid in a capacious flask or retort; pure carbonic oxide soon begins to be evolved in very large quantity. Carbonic oxide is also produced, along with hydrogen, when steam is passed over ignited charcoal or coke; it is also an invariable constituent in coal gas, which contains on an average about 10 per cent. of this gas. The properties of this gas are, that it is colourless and insipid; it is but slightly dissolved by water; it is fatal to animals, and extinguishes a taper if immersed in it; but when it meets with oxygen gas it burns on ignition, and is converted into carbonic acid. It has no action upon blue vegetable colours; and, unlike carbonic acid, it does not occasion any precipitation in lime water.

Carbonic oxide is composed of

$$\begin{array}{rcl} 1 \text{ Equivalent of oxygen} & = & 8 \\ 1 \text{ " carbon} & = & 6 \\ \hline \text{Equivalent} & = & 14 \end{array}$$

It is hypothetically considered as constituted of 100 volumes of the vapour of carbon and 50 volumes of oxygen gas, condensed into 100 volumes. One hundred cubic inches weigh 30.1 grains; its density is therefore to that of atmospheric air as .971 to 1. When electric sparks are passed through carbonic acid gas, confined over mercury, a portion of it is converted into carbonic oxide and oxygen gases.

CARBOVINIC ACID. [ETHYL.]

CARBUREIC ACID. A synonym for allophanic acid. [ALLOPHANIC ACID.]

CARBURET, or **CARBIDE**, a term designating a compound of carbon with certain other bodies, as nitrogen and some of the metals, &c.

CARBURET OF IRON. [STEEL.]

CARBURET OF NITROGEN. [CYANOGEN.]

CARBURETS OF HYDROGEN. [HYDROCARBONS.]

CARCASS, a shell, or hollow ball of iron, perforated in three places at equal distances from each other, within one hemisphere of the shell, and filled with a composition which burns with violence during eight or ten minutes. When discharged from a mortar or howitzer, the flames issuing from the perforations or fuze-holes set fire to any building on which the carcass may happen to fall.

CARD-MAKING. The name of cards is given to two kinds of manufactured commodities, so utterly unlike each other that it is difficult to conceive how it came to be so appropriated. One kind of card is a flat piece of pasteboard applied to many purposes of business or pleasure; the other is a series of sharp metal spikes set into a leather support, for carding or opening the fibres of cotton in the cotton manufacture. We shall describe the manufacture of both these kinds of cards, keeping them distinct, on account of their possessing no other connection than that due to the similarity of name.

Playing-cards. Neither the country nor the date of the introduction of playing-cards is correctly known, great diversity of opinion existing on both these points. It is believed that the figures and spots of the first cards were stencilled, and that the use of wood-blocks for printing them was of later introduction. It is known that there have been playing-card makers in this country for nearly four centuries. In India, cards are often made quite circular in form. In Russia, until within the last few years, the importation of playing-cards was strictly prohibited; there was an imperial manufactory kept up at Alexandroffski, near St. Petersburg, the profits being applied to the maintenance of the Foundling Hospital in that city. The manufactory contained many of the best forms of apparatus invented by De la Rue and Applegath; and the produce usually amounted to the enormous quantity of 14,000 packs of playing-cards per day.

The carton or pasteboard for playing-cards is formed of several layers of paper pasted together, each layer or sheet being large enough for forty average cards. The layers are four in number, all selected with especial reference to many requisite qualities, especially those for the face and the back. The pasting is very carefully conducted, and is followed by cool drying, hot drying, and heavy pressure. The outer surfaces undergo a peculiar treatment; if the cards are to be "white," the surface is furnished with a kind of flinty coating, in order that the black and red for the pips, and the varied colours for the court-cards, may come out clear and sharp; if they are to be "coloured backs," the ground tint is laid on by a regular colouring process, and the coloured surface is then further prepared for the reception of a pattern or device. The colouring material here spoken of is mixed with size and water, and applied with a brush. Messrs. De la Rue, who have carried this art to a higher pitch of excellence than any other English manufacturer, employ tasteful designers to produce elegant patterns for the backs of cards; and much mechanical and chemical skill has been displayed in devising new modes of colour-printing for this purpose. Some of the combinations of gold and colour are exceedingly beautiful. The number of cards in each pack is, as is well known, 52; but there have been exceptions to this number both in past and present times. The number of suits with us is always four, but in the East, and in Europe in earlier days, there were many instances of higher numbers. With us, the hearts, diamonds, spades, and clubs, are the only varieties; but in other days and countries there have been leaves, acorns, bells, cups, swords, batons, coins, pine-apples, heads, squares, ovals, circles, fishes, tortoises, lions, goats, horses, boats, axes, and other devices. Lastly, our court-, or coat- (as Mr. Chatto designates them), cards are now always kings, queens, and knaves; but the history of playing cards presents us with a curious medley of officers, subalterns, valets, virtues, heroes, savans, &c. The fixity of character in modern cards is certainly an advantage to the manufacturer; since he may make millions of packs without caring for any important modification. Messrs. De la Rue some years ago, spent a large sum of money, and much thought and labour, in an endeavour to introduce graceful figures instead of the monstrosities with which we are familiar under the names of kings, queens, and knaves; but the public had become accustomed to these latter, as to the conventional "willow-pattern" for dinner plates; and the attempt was abandoned at a heavy loss.

Most of the London card-makers employ the mode of stencilling, not printing, for the pips and pictures. A stencil-plate is cut out, and the colour, mixed with paste, is brushed on the sheet through the holes in the stencil-plate—a process requiring very nice manipulation, to prevent the colour from spreading beyond the margin of the stencil-holes. Some parts of the picture cannot be done by stencilling; they require the use of engraved wood blocks; and some manufacturers employ blocks altogether. Stencilling may be done on the paper either before or after it is pasted to other papers to make the cardboard; but the printed cards must be done before the pasting. The best cards are now printed in oil colours, on the principle of colour-printing of some other kinds—after the expenditure of much time and ingenuity in ensuring that the pip shall be equal-tinted, the outline clear and sharp, the colour well adhesive to the paper, the removal of all clamminess or stickiness, and the susceptibility of receiving a high polish. When the stencilling and printing have been completed, and the four thicknesses of paper properly pasted together, the cardboard is dried, polished, and rolled to a high degree of gloss. The ace of spades is printed under a wholly different and peculiar arrangement, to insure the payment of one shilling duty to Her Majesty on every pack of cards. Each carton or cardboard, having forty cards imprinted on it, is cut up into forty pieces by an apparatus similar to that used by bookbinders for cutting millboard. Every card is then minutely examined: and packs of fifty-two are made up from those which resemble each other as closely as possible in tint and general excellence. The strange technical names of "Mogul," "Harry," and "Highlander," are given to three qualities into which the cards are sorted; if they are not good enough for "Highlanders," they are thrown aside as waste cards. When the packs are arranged and made up, an exciseman attends to witness the wrapping in stamped papers.

A few years ago it was supposed that about 500,000 packs of playing cards were made in London annually.

It is not necessary to describe the manufacture of any other kinds of

cards made of cardboard or pasteboard, such as visiting or address cards; seeing that they exhibit similar applications of some of the same operations as those described above.

Cards for Carding Engines.—In the cotton manufacture, one of the early processes consists in disentangling the fibres of cotton, so as to re-arrange them in a position more or less parallel, free from knots or other interruptions. The instrument employed for this purpose is a kind of brush called a "card," set with wire-teeth disposed in a regular manner. The action of this instrument is very similar to that of a comb for hair, or a heckle for flax and hemp, the fibres being made to pass between the teeth, or the teeth between the fibres, according to the arrangement of the mechanism. The wire teeth of the cards are inserted in carefully-prepared strips of leather, which used formerly to be affixed to flat handles or supports, but are at the present day bent round the exterior surface of a cylinder. Several such cylinders being arranged nearly in contact, and fibres of cotton being laid within reach of one of them, the cylinders by their rotation catch up the fibres, pass them on from one to another, and comb out or straighten them in the transit.

When the manufacture was in a ruder and less important position than at present, these cards were made by hand; the leather being dressed and cut, the holes pierced, the wire straightened and brought to the necessary shape, the teeth cut off and inserted into the holes in the leather, by persons who made this a regular branch of employment. But machines are now employed to effect this, so intricate and beautiful in construction as to have been often alluded to as among the most admirable pieces of mechanism known in our workshops and factories. It was in the year 1811, that Mr. Dyer, of Manchester, first took out a patent for one of these machines; two other patents were obtained in 1814 and 1824; and more recently further improvements have been made in the construction by Mr. Walton and other inventors.

The machine consists of a large number of levers or rods, capable of motion in various directions, and moving one after another in a particular and definite order. The different kinds of work to be performed by it are so numerous and so dissimilar, that the mass of details becomes exceedingly complex, and not easily followed even with the aid of wood-cuts. In the first place, the strips of leather which are to form the cards are attached to the machine, in such a way as to shift laterally as fast as they are supplied with wires. A series of forks or points are thrust out, to pierce holes of the requisite depth in the leather, and are drawn back again when this is effected; sliding pincers unwind the wire from a coil, and bring it forward; a moveable cutter descends upon each wire, and cuts off a piece long enough for one of the teeth; a blunt kind of stud or rod presses against the middle of the piece so cut off, and presses it into a horse-shoe or rather a staple-shape, with the two points parallel; each staple or tooth is seized by nippers, thrust half way into a hole in the leather, bent angularly by another piece of apparatus, so as to give an exactly determined obliquity to it, and lastly driven home to its proper depth in the hole. All this is effected by successive movements in the different parts of the machine; and several teeth, forming those in one row, are made and fixed at once. When one cycle or series of the processes is completed, the leather is made to shift onwards through a small space, and to present a new surface for the reception of teeth.

The efficiency of the machine was such, even some years ago, that a steam-engine of five-horse power could set a hundred of them at work, while each machine could make and fix from a hundred to a hundred and fifty teeth in a minute; but successive improvements have so increased the power, that now four or five hundred teeth are formed in the same space of time. There are not often opportunities of seeing these beautiful machines, except in the Lancashire and Yorkshire districts; but occasionally they are exhibited at Mechanics' and Scientific Institutions, and of late years at the greater international exhibitions.

So large is the consumption of this kind of 'garniture,' as it is called, for the carding-engines of the cotton districts, that—at a time when the cotton manufacture barely exceeded one-half of its present amount—it was estimated that four thousand hides and forty-eight thousand feet of wire were cut up weekly to make them. The wires are inserted in leather, because the flexibility of this material allows it to be bent round the surface of a cylinder. Patents have been taken out for improving the surface of these leathers. If a hard and tangled tuft of cotton occurs in the process of carding, the rigidity of the surface of the leather prevents the tooth from bending or yielding to the obstruction; and it has been proposed to remedy this by applying to the face of the leather, before the wires are inserted in it, a coating of woollen cloth, saturated with caoutchouc to render it very pliable. Another suggestion is for the use of a textile material, with a warp of hemp, flax, or cotton, and a weft of woollen, saturated in like manner with a solution of caoutchouc. But both are alike in their object, and have relation only to the minor working of the method, the card-making machine being independent of them.

CARDAMINE PRATENSIS—*Medical properties of.* This indigenous herbaceous plant decorates our meadows and pastures in April and May, with its light purple reticulately veined flowers, which are the official parts. They possess a faint mellifluous odour, which is nearly lost by drying. The taste is acrid and pungent, similar to but

less agreeable than that of the common watercress, which is dissipated by age. The chief constituents are a bitter extractive and a volatile oil. To these it is indebted for such medical powers as it possesses, which are very slight, altogether insufficient to entitle it to a place in the Pharmacopœia. It is said to be stimulating, diuretic, and antispasmodic; and hence of service in hysteria, chorea, and epilepsy. In some of the slighter cases of these, dependent on irritation of the intestinal canal, from imperfectly digested food, unhealthy secretions, or worms, it may, along with purgatives, bitters, and exercise, be of some benefit. It is however as an anti-scorbutic herb that it is best entitled to notice. The health of many persons is low in early spring from the want of green vegetables during winter, and the blood passes into the condition which obtains in persons suffering from scurvy. The use of fresh vegetables, such as this and watercresses, with fruits and lemon-juice, will speedily remove this state.

(Lecture of Dr. Budd on *Scurvy*, in *London Medical Gazette*, vol. xxxii. p. 713.)

CARDAMOM, Essential Oil of. This oil is obtained by distilling cardamom seeds with water. It is colourless, possessing a strong aromatic taste, and an agreeable odour. Its specific gravity is .943. It has the same composition as *camphen*, namely, $C_{10}H_8$.

CARDAMOMS are the aromatic capsules and the seeds of different species of several genera of plants formed out of the original genus *Amomum* of Linnæus. They are all natives of the hotter parts of the world, the respective kinds being distinguished in commerce either by their form, or designated by the names of the countries or provinces whence they are supposed to come. The genus *Elettaria* (Rheede *Matonia* of Smith, in Rees' 'Cyclop.') yields the only kind of cardamoms admitted into the present (edition 1851) 'London Pharmacopœia.' Besides these, several are known in Continental commerce under the name *Amomum*, which have neither the characters nor qualities of true cardamoms. Thus, the *Sison Amomum*, the *Hedge Honewort*, or *Bastard Stone Parsley* of our hedges, called *German Amomum*, yields a fruit (erroneously called *seed*) which, when dry, is aromatic, pungent, and pleasant, but when fresh is more calculated to disgust and repel than attract. Likewise the fruit or unripe berries of the *Eugenia* (*Myrtus*), pimento berries, allspice, or Jamaica pepper, are called in Germany *Semen Amomi*, or *Baccæ Amomi*. But as they are aromatic stimulants, like cardamoms, any possible confusion of them is of less consequence. In giving an account of the appearances and supposed sources of cardamoms, the authority most to be depended on is the late Dr. Pereira, who has taken great pains in investigating this subject. (See his 'Elements of Materia Medica,' last ed., 1850, p. 1129, and various papers in earlier volumes of the 'Journal of the Pharmaceutical Society.')

1. The cluster or round cardamoms yielded by *Amomum cardamomum* of Linnæus, supposed to be the *κάρυον* of Dioscorides (lib. i. cap. xix.), the *Amomi uva* of Pliny ('Hist. Nat.,' lib. xii. cap. xxviii.), a native of Sumatra, Java, and other islands to the eastward of the Bay of Bengal. The fruit varies in size from that of a pea to a cherry. When they occur in their native clusters or spikes, they constitute the *Amomum racemosum*; when distinct, simply round cardamoms. The seeds are brown, angular, wedge-shaped, somewhat shrivelled, with an aromatic camphor-like flavour. These are more employed in the South of Europe than with us, but they are official in the French Codex and the Dublin Pharmacopœia. They possess, though in less degree, the qualities of the Malabar cardamoms.

2. *Amomum Granum Paradisi*, Afzel. et *A. Melegueta*, Roscoe.—The name *grains of paradise* are given to the seeds of the two species of *Amomum* cited here,—called also Guinea grains, while Malagueta pepper is given to the latter only; yet the term Malagueta pepper is also given to the fruit of the *Eugenia pimenta*. *Maniguetta* is likewise sometimes given as a name to the *grains of paradise*; but this is properly the designation of the fruit or seeds of *Unona æthiopica*, called, from its pungent qualities, *Piper æthiopicum*, but not a species of the genus *Piper*.

The two sorts of seeds to which the term *grains of paradise* should be restricted grow in Africa, probably widely apart, as they find their way to different parts of the coast, and are held in commerce to be very different in value.

Amomum Granum Paradisi, Afzelius, and Smith (in Rees' 'Cyc.,' vol. xxiii., art. 'Mellegetta;' and vol. xxix., suppl., art. 'Amomum'), native of Guinea, about Sierra Leone. The capsule is about an inch long, half an inch in diameter, oblong, bluntly triangular, somewhat ovate, beaked, of a dark reddish-brown, ribbed, coriaceous, rough, with minute deciduous bristly hairs. This, when broken, gives a powerful aromatic odour, which it retains even for twenty years. The seeds within are numerous, enveloped in membranes formed of the dried pulp; when freed from this they appear roundish or angular, of a shining golden colour inclining to brown; when old, minutely rough or granulated; when bitten, extremely hot, acrid, and pungent.

The *Amomum Melegueta* (Roscoe) is cultivated in Denmark, probably introduced from Africa. The seed-vessel and seeds are larger than those of *A. Granum Paradisi*.

In commerce the two sorts are distinguished as: 1. Guinea grains from Cape Palmas and Sierra Leone, supposed to be the produce of *A. Granum Paradisi*; less esteemed than—2. Guinea grains from Acra; larger and plumper than the preceding, as well as more warty. They

have also on the umbilicus of the seed a short, conical, projecting tuft of pale-coloured fibres. Considered to be the produce of *A. Melegueta* (Roscoe).

The chemical composition of grains of paradise, according to the analysis of Willert, in 1811, appears to be—

Volatile oil	0.52
Acrid resin	3.40
Extractive	1.27
Tragacanthine and woody fibre	82.8
Water and loss	12.0
	99.99

The active constituents are the volatile oil, which is of a light yellow colour, with camphor-like odour, and very hot penetrating taste, and the resin. This is soft, brown, devoid of odour, but with an acrid burning taste.

While the native Africans justly esteem these fruits and seeds as the most wholesome of aromatics, and employ them in many of their dishes, prejudice restricts the employment of them in England, either as veterinary medicine or as an ingredient in liqueurs or cordials, their use for which is absurdly prohibited by heavy penalties. Being exempt on the Continent, large use is there made of them. (Jullien, 'Manuel du Sommelier.')

Amomum maximum (Roxb.), yields the greater Java cardamoms, the Nepaul cardamoms, and Bengal cardamoms. These are easily distinguished by immersing the dried capsules in hot water, when they immediately swell, become globular, and evolve from nine to thirteen elevated ridges terminating in their membranaceous wings. The seeds are larger than those of grains of paradise, and have a dull dirty brown hue. The taste and odour are only feebly aromatic, and they contain far less volatile oil, which is whitish. They are chiefly exported from this country in bond, for use on the Continent.

The *Amomum Korarima* yields the *Cardamomum majus* of Valerius Cordus, a still feebler species. The term *Cardamomum majus* has also been given to the fruit of an unknown species, which Dr. Pereira has proposed to call *Amomum citratum*, from the agreeable lemon grass-like odour of the seeds. These have sometimes been termed Grains of Paradise, but the seeds appear larger than the common ones.

The *Amomum Clusii* deserves notice, not only because the seeds receive the name of "Bastard Mellegetta" from the natives around Fernando Po, where they are abundant, but on account of the use made by them of the pulp in which the seeds are imbedded. This is of a soft consistence, acidulous, and of a pleasant flavour. Either alone, or diluted with water, this natural compound has a most beneficial effect in allaying thirst or soothing the intestinal canal when irritated by purgatives or disease, such as dysentery. Similar natural combinations are used by the natives of various hot countries; such as the pulp of the *Adansonia digitata* in Senegal, and the *Tamarindus Indica* in the East Indies, and *Tamarindus occidentalis* in the West.

Amomum macrospermum (Smith; *Zingiber Melegueta*, Gaertner), only deserves notice as having been erroneously asserted by Trew to produce from its seeds the Cajuput oil of commerce. Though a native of Sierra Leone, the fruit is termed sometimes *Cardamomum bandaense*. The natives suck the acidulous juice of the capsule.

The *Elettaria cardamomum* (Maton), yields the true or official cardamom, called likewise Malabar cardamom. The fruit and seeds are official. The seeds are more potent when kept in the capsule till about to be used. They are either collected from wild plants or cultivated,—the best from the latter, especially such as are produced at Wynaad. The wild plants are so abundant in the Ghauts of Caduti-nada, and near Mahé, that the hills are called the Mountains of Cardamoms (Fee). The capsules occur in commerce in three forms,—*shorts*, *short-longs*, and *long-longs*. The shorter are the most esteemed; they are probably collected earlier than the others, and while possessed of more aromatic pungent flavour. According to the analysis of the shorts by Trommsdorff, in 1834, they contain—

Essential oil	4.6
Fixed oil	10.4
A salt (malate?) of potash, with colouring matter	2.5
Starch	3.0
Nitrogenous mucilage, with phosphate of lime	1.8
Yellow colouring matter	0.4
Woody fibre	77.3

The volatile oil is the active ingredient. Cardamoms are perhaps the best and most esteemed of all aromatic stimulants; they enter into various pharmaceutical compounds, especially two tinctures, a simple and compound one. It is an ingredient in many dishes in the East, especially curries. [CURCUMA.]

CARDINAL, the highest dignity in the Roman Church and court, next to the pope. The cardinals are the electors of the pope, and his councillors.

The term is derived from the Latin adjective "cardinalis," which means "principal," or from the substantive "cardo," which means a "hinge," the cardinals being the hinges or supports of the Church, and

the pillars of the Roman clergy. There were also cardinal deacons, who had the charge of the hospitals for the poor, and who ranked above the other deacons. Originally, this title appears to have been applied to the highest offices, but about the 11th century it became restricted to the incumbents of the parishes of the city of Rome, and also of other great cities, who alone had the power to baptise and to administer the Lord's Supper. The cardinal priests of Rome attended the pope on solemn occasions. Leo IV., in the council of Rome, 853, styled them "presbyteros sui cardinis." Afterwards the title of cardinal was given also to the seven bishops suburbicarii, or suffragan of the pope, who took their title from places in the neighbourhood of Rome; namely, Ostia, Porto, Santa Rufina, Sabina, Palestrina, Albano, and Frascati. These bishops were called hebdomadarii, because they attended the pope for a week each in his turn. The cardinals took part with the rest of the Roman clergy in the election of the pope, who was often chosen from among their number, till 1058, when, having chosen Nicholas II. without the participation of the people, the right of doing so was decreed by the pope in the following year; and in 1179, the election was more solemnly restricted to the cardinals only by Alexander III. About the beginning of the 12th century, the popes having organised a regular court, bestowed the rank of cardinal priest or deacon on any individual of the clergy or even laity that they thought proper, whether Roman or foreign, giving to each the title of some particular church of Rome, without any obligatory service being attached to it. The churches which give titles are, however, even yet, under the complete jurisdiction of their respective titulars. Thus they made the cardinals a separate body elected for life; and the officiating priests of the Roman parishes were by degrees deprived of the title of cardinals. Sixtus V., in 1587, fixed the number of cardinals at seventy, which has been since increased to seventy-two; namely, the six bishops suburbicarii above-mentioned (the title of Santa Rufina being joined to that of Porto, and that of Velletri added to Ostia), fifty-two cardinal priests, and fourteen deacons. Most of the cardinals, both priests and deacons, bear the title of a church of the city of Rome. Several of the cardinal priests are bishops of some particular diocese at the same time; still they bear the title of the particular church of Rome under which they were made cardinals. The body of the cardinals is styled the Sacred College. The number of seventy-two is seldom complete, the pope generally leaving some vacancies for extraordinary cases. Most of the cardinals who reside at Rome, either enjoy ecclesiastical benefices, or are employed in the administration, either spiritual or temporal; others belong to wealthy families, and provide for their own support; and those who have not the same means, receive an allowance from the government. Their dress, adopted before the commencement of the 13th century, was a scarlet or violet robe and nose, symbolising their readiness to shed their blood for the Catholic faith. In 1243, Innocent IV. gave them the red hat, and precedence over bishops; Boniface IV. added the princely mantle, and Urban VIII. gave them the title of "Eminence." The nomination or promotion of any one to the cardinalate rests wholly with the pope; and their institution is accompanied by the ceremony of kissing the pope's foot, hand, and mouth, and by others symbolical of their spiritual allegiance. The pope often employs cardinals as his ambassadors to foreign courts, and the individual thus employed is styled Legate *a Latere*. A cardinal legate is the governor of a province, known by the name of a Legation, whereof, till the revolution of 1830, there were four. The chief secretary of state, the camerlengo or minister of finances, the vicar of Rome, and other leading official persons, are chosen from among the cardinals.

The Council of Cardinals, when assembled under the presidency of the pope to discuss matters of Church or state, is called "Consistorium." There are public consistories, held on some great occasions, which correspond to the levees of other sovereigns, and private or secret consistories, which are the privy council of the pope. With regard to the forms of the election of a pope, see CONCLAVE.

In Moreri's Dictionary, art. "Cardinal," is a list of all the cardinals elected from 1119, till 1724, their names, countries, titles, and other dignities, the date of their election, and that of their death, which may be found useful for historical reference.

CARDINAL POINTS. [COMPASS.]

CARDING. [WOOLLEN MANUFACTURES.]

CARDITIS, inflammation of the heart. [HEART, DISEASES OF.]

CARILLON. [CHIMES.]

CARMIDINE. An organic base found in shale tar. It has hitherto only been imperfectly examined.

CARMINATIVES, agents chiefly obtained from the vegetable kingdom, are employed to promote the expulsion of flatulence. Though gases of different kinds are occasionally secreted by the inner surface of several organs of the body, those gases which infest the intestinal canal are in a great measure the result of the fermentation of articles of food, the digestion of which is slow or imperfect. Whatever causes indigestion favours the formation of such gases; hence they mostly trouble infants, whose stomachs are generally feeble, or hypochondriacal and hysterical individuals, or those who lead a sedentary life. Substances which impart, even for a very short time, that energy and power which, in such persons, the stomach and intestines appear to be destitute of, enable them to throw off the wind which oppresses these organs. Plants possessed of an aromatic principle, owing to the pre-

sence of a volatile oil, are employed to effect this end, which they sometimes accomplish even when applied to the external surface of the stomach, and much more certainly when taken internally. Instead of the plants in a raw or dried state, the oil is often extracted from them by distillation, or a tincture or even a distilled water is formed from them, and administered under similar circumstances; and this last mode is in general the best. A few drops of the oil, or of the tincture of any of these plants, may be dropped upon sugar, and so introduced into the stomach, or the distilled water may be made the vehicle for the administration of other medicines proper to be given at the same time. Thus some alkaline earth, such as magnesia or its carbonate, or a pure alkali, such as liquor potassæ, or an alkaline carbonate, may be given at the same time with good effect.

As a general rule, it may be stated that, if these stimulants fail on their first exhibition to give the relief expected, they should not be repeated without the sanction and advice of a competent medical attendant; for, even if an inflammatory condition of the stomach and intestines does not already exist, the continuance of colicky pains is apt to produce it, especially if assisted by brandy or other stimulants. Even dill or anise may affect too powerfully the sensitive nervous system of infants, for these are by no means such simple agents as is commonly supposed: the seeds of dill poison bullfinches, canary birds are killed by those of anise, and parrots by those of parsley.

The safest and most effectual means of avoiding the distressing symptoms attendant on the disengagement of flatus are great attention to diet and regimen. Regular exercise should be taken daily. The food should be plain; soups and much liquid, particularly tea, should be avoided: and the person should retire to rest at an early hour. [AROMATICS, ANTISPASMODICS.]

CARMINDIN. [INDIGO.]

CARMINE, as met with in commerce, consists of the colouring matter (*carminic acid*, *cochenillin*) of the cochineal insect (*Coccus cacti*, ord. *Hemiptera*), united generally with alumina, sometimes with oxide of tin, and occasionally it contains albumen, on account of white of egg having been used in its manufacture. The following are some formulæ for the preparation of this beautiful pigment:—

One pound four ounces of cochineal and 115 grains of carbonate of soda are to be boiled with four gallons of rain-water, or, better, distilled water, for twenty minutes; and, after removing from the fire, three-quarters of an ounce of alum and the eighth of an ounce of bitartrate of potash are to be added, and the whole well stirred. On standing, impurities subside, and the liquor may be carefully decanted off and strained if necessary. It will now soon become turbid, when the whites of two eggs, well beaten up, are added, and if complete separation of the colouring matter does not immediately take place the whole may be gradually heated, when the carmine soon rises to the surface. The liquor should not be boiled. Collected on a strainer, the carmine, after washing with three or four pints of water, is to be dried at a temperature between 82° and 86° Fahr. Isinglass may be substituted for white of egg if a less granular carmine is desired.

In the preparation of carmine, great delicacy of manipulation and perfect purity of material is necessary; the heat required should be generated from a charcoal fire, and all vessels kept scrupulously clean; even the atmosphere of a large town is said to injuriously affect its tint.

Carmine is largely used in miniature painting, artificial-flower making, perfumery, confectionery, red ink manufacture, and as a cosmetic, sometimes called rouge, for the complexion. It is richer, more transparent, and a smaller quantity goes further than any other colour of similar hue.

Carminic acid (*cochenillin*), (C₂₈H₁₄O₁₆), is the pure colouring matter of the cochineal insect mentioned already. Mr. Warren De la Rue, who has made an elaborate investigation of this substance, recommends the following process for its preparation: An aqueous decoction of the powdered cochineal is to be precipitated with acetate of lead, the washed carminate decomposed by a stream of sulphuretted hydrogen, and the carminic acid again precipitated with acetate of lead previously mixed with acetic acid. The carminate of lead is once more decomposed with sulphuretted hydrogen, the solution evaporated to dryness, re-dissolved in alcohol and phosphoric acid, and separated by digesting the tincture with a small quantity of carminate of lead. Lastly, a trace of nitrogenous matter being separated by ether, the pure carminic acid is obtained from the filtrate by evaporation.

Carminic acid is a purple-brown friable solid, transparent under the microscope. It is easily ground to a fine red powder. It is very soluble in water and alcohol, and in hydrochloric and sulphuric acids; but only slightly so in ether. Chlorine, iodine, and bromine decompose it. It may be heated to a temperature of 245° Fahr. without injury; a higher heat causes decomposition. Nitric acid very readily attacks it, a mixture of oxalic and nitrococcusic acids being produced. [NITROCOCUSIC ACID.] The alkalis combine with carminic acid, forming rich purple colours, soluble in water, but not in alcohol. The alkaline earths produce purple precipitates, and sulphate of alumina and ammonia carries down a beautiful crimson lake from solutions of this acid. It may also be made to combine with lead, copper, zinc, and silver.

CARMINIC ACID. [CARMINE.]

CARMUFELLIC ACID (C₂₄H₂₀O₃₂). An organic acid, said to be

obtained by the action of nitric acid upon the aqueous extract of cloves.

CARNIVAL, or **CARNEVAL**, from the Italian *Carnevale*, or Farewell to Flesh. It is properly a season of feasting, dancing, masquerading, and buffoonery, which begins on the Feast of the Epiphany, or Twelfth Day, and ends on Ash-Wednesday, when it is succeeded by the austerities of Lent. Some of the licence of the Saturnalia of the ancient Romans is still detected in these long revels, which are now confined to Roman Catholic countries, and seem to be declining even in them. Milan, Rome, and Naples were celebrated for their carnivals, but they were carried to their highest perfection at Venice,

The pleasant place of all festivity,
The revel of the earth, the mask of Italy.

In modern Rome, the masquerading in the streets and all the out-of-door amusements are limited to eight days, during which people pelt each other with sugar-plums, and are treated with horse-races, in which horses run without any riders on their backs. After the races of the eighth day, masquers go about with tapers in their hands, every one trying to light his own at his neighbour's candle, and then blow out his flame. This is the last of their frolics, and about as rational as any part of a Roman carnival. Göthe, in his 'Zweiter Romischer Aufenthalt,' has given a vivid and pleasing description of the Roman carnival.

CAR'OL (*Carola*, Ital.), a song of joy, and we use it in this sense when we speak of the carolling of birds. Boccaccio seems to have considered the term as synonymous with *ballata*, which, according to the dictionary *Della Crusca*, signified a song sung during a dance. In England the term was formerly given to festal songs sung to celebrate Christmas; but it is now exclusively applied to a religious song or ballad in celebration of Christmas, still sung during the festive season in many parts of the country, though in the present day seldom heard in the metropolis.

CAROTIN ($C_{10}H_8$) the colouring matter of the common carrot, *Daucus Carota*.

CARPENTRY is defined by Robison as "the art of framing timber for the purposes of architecture, machinery, and in general for all considerable structures." Considered as a branch of the art of building, it embraces the construction of the framing of partitions, floors, and roofs; the neater woodwork of doors, window-frames, the planking of floors, skirtings, and stairs, being the work of the joiner. [JOINERY.]

As in the article **BUILDING**, our object here is rather to point out and connect various articles in other parts of the Cyclopædia, than to present even a complete outline of the theory and practice of carpentry; seeing that such a subject would involve a knowledge of the nature and properties of various descriptions of timber—of the strength of materials exposed to various kinds of strain—of the mechanical principles involved in the construction of trusses, roofs, and the various framings which tend to bind the several parts of a building together, or to sustain and distribute pressure—and of the practical details relating to the cutting up of timber, and the union of several pieces by various kinds of joints and connections.

Of the properties of timber an account is given under **WOOD**; and also, in connection with other matters relating to theoretical carpentry, under **MATERIALS**, **STRENGTH OF**. Of the woods used in carpentry in this country, oak is one of the most durable, though its comparatively high price, and the difficulty of working it, restrict its use. It should be borne in mind however, that the irregular direction of the fibres of oak greatly impairs its strength when sawn into beams and planks, so that a sawn beam of oak may be weaker than one of equal size of fir, because in the latter the fibres extend in almost perfectly straight lines from end to end, while in the former their course is so tortuous that those which come near the surface are frequently cut through by the saw. Hence arises the superiority, for some purposes, of split over sawn timber. Fir, which is very easy to work, and is peculiarly advantageous for house carpentry on account of its straightness, is the timber most extensively used by English carpenters. The supply is chiefly from foreign countries, and the principal forms in which it is brought are those of *baulks*, or large beams of various sizes, each of which consists of a whole trunk roughly squared; *deals* and *deal-ends* [DEALS], which are boards from 2½ to 4 inches thick, and more than 7 inches wide; and *battens* and *batten-ends* [BATTENS], which are similar to deals, but only 7 inches wide. Various technical terms are applied to the smaller pieces of timber cut out of baulks, deals, and battens, the transverse dimensions of which are frequently called their *scantling*. By the drying up and evaporation of its vegetable juices, timber will continue to shrink for a considerable time after it is hewn, and in so doing it frequently warps or winds, and splits, or becomes *shakey* or full of longitudinal cracks, which are usually in a radiating direction as regards the centre or heart of the tree. The shrinkage alluded to is almost entirely in a lateral direction, the length of a piece of timber, in the direction of its fibres, being affected only in a very trifling degree. To prevent as far as possible the injurious effects of shrinking, warping, and flying or cracking, timber should be well seasoned by long exposure to a current of air before it is used, an object which is effected by various modes of stacking and piling with interstitial openings for the admission of air; but as no ordinary amount of seasoning will perfectly accomplish the desired object, precautions

should be adopted to lessen the evil of subsequent shrinkage. Where it is required to bend timbers they are softened by boiling or steaming, or by the direct action of fire, then brought to the required shape, and secured at the proper curvature until they become cold and dry, when they will retain their new form with very little variation. For the various modes of cutting timber see the articles **SAW**, **SAW-MILL**, and **WOOD-CUTTING MACHINERY**; and for a notice of the principal boring tools used by the carpenter, see **BORING INSTRUMENTS**.

Of the employment of timber in immediate connection with brick-work, as in bond-timbers, wall-plates, camber beams over doorways and windows, &c., a notice will be found under **BUILDING**; and in the articles **ROOF** and **FLOOR**, will be found most of the information required in a work of this character on carpentry, as connected with building. In **ROOF** especially, and in the account of centering under that head, an explanation is given of those elementary principles of trussing, or combining several pieces of timber into a rigid framework in which the strength of each of them is used to the greatest advantage, which must be applied, with such modifications as circumstances may dictate, to almost every construction in carpentry; while under **TRUSSING**, the application of the same principles to the support of large beams or girders is explained. The construction of timber partition-walls, or rather of the timber framing of such partition-walls, as are covered with lath and plaster, though based on the same general principles as are involved in the trusses of a roof, may be noticed here, because, though a distinct branch of carpentry, it does not, like the construction of floors, demand a separate article.

Partitions formed of brick-nogging, or of brickwork included within the intermediate spaces of a timber framing, are noticed under **BUILDING**; and as, from their weight, they are inapplicable excepting in cases where there is a solid bearing or foundation for the whole length of the partition, as in basement partitions, or in such partitions of upper rooms as are immediately over partition-walls rising from the basement, they call for but little skill in the arrangement of the timbers. In the construction of such partitions, or of ordinary lath and plaster ones, which are sometimes called (from the use of small timbers denominated quartering) *quarter partitions*, wherever they rest upon a solid basis, it is sufficient to fill the rectangular framing which bounds the partition at the sides, top, and bottom with a series of upright rectangular bars, the greatest width or thickness of which is disposed in a direction at right angles with the face of the partition. These upright timbers, or quarterings, are placed at uniform distances from each other, the intervening spaces being, in a brick-nogging partition, either eighteen or twenty-seven inches, so as to receive either two or three bricks in length, while in other cases they are usually less, or from twelve to fourteen inches, according to the strength of the laths used upon them; and the depth of the quarterings, which regulates the thickness of the partition, is usually from three to five inches. Those for brick-nogging, where the surface is to be covered with lath and plaster, should somewhat exceed the thickness of the brick-work, so as to allow for irregularities in the form of the laths. When, however, the floor upon which the partition rests is not solid, but is unsupported in the centre, the whole stress should be borne by the extremities of the lower edge of the partition, and this should be constructed as nearly as possible like the trusses of a roof, and should be capable of affording support to the floor above it, and also, if needful, to that below it, on which it appears to rest. The simplest mode of accomplishing this is to insert in the frame two inclined bars or struts, resembling rafters, abutting upon the lower corners of the partition, which struts of course must be firmly supported by the timbers of the floor at the point where they rest upon the wall-plates, or are otherwise immovably connected with the brickwork, and either meet in the centre of the top of the partition, or be framed into the head of a central upright timber resembling a king-post, which, like it,

Framed king-post partition.

may be made to assist in supporting the middle portion of the bottom of the partition, and, if needful, the floor beneath it also. In either

case, the point of meeting becomes a fixed point for supporting the ceiling or floor above it. If the length of the partition be too great for this arrangement, or if a doorway be required where the central post would come, two posts may be used instead of one, with an horizontal bar of wood between their upper ends; or, in fact, a queen truss may be formed. The diagonal bars are called *braces*, and the

Framed queen-post partition.

horizontal piece between the posts is sometimes called an *intertie*; but these names are objectionable, because the action of the pieces in question is the reverse of that of a tie, or of what would be generally understood by a brace. Doorways often derange the bracing of partitions, and sometimes render it impossible to retain the advantage of the tie afforded by the bottom piece of the rectangular frame which bounds the partition. In some cases the *intertie*, or rather collar-beam forms the head of the doorway; but as the doorway is mostly much lower than the partition, it is not unusual to extend the horizontal piece which forms the head of the doorway to the extent of the whole length of the partition; it is also usual to form the long rectangular space above it, and the rectangular spaces below it on each side of the doorway, or the whole space below it, including the doorway, into separate trusses. The long unbroken truss above the doorway may indeed be made to support the whole partition without the aid of bracing in the lower compartments. Sometimes, instead of the ordinary mode of bracing, which necessarily interferes with the fixing of the upright quarterings to which the laths are to be attached, a mode of bracing with parabolic arches of iron or wood is adopted. The usual mode of bracing is occasionally used for brick-nogging partitions, or, in rural cottages, for the brick-nogging of external walls; but of course its adoption occasions much trouble in cutting the bricks to fit the oblique lines and angles produced by the braces.

Respecting the various kinds of joints required in carpenter's work, information will be found under ROOF and SCARFING. Robison mentions an ingenious modification of the common mortise-and-tenon joint which is worthy of notice, under the name of *fox-tail wedging*. It consists in the insertion in the end of the tenon of a thin wedge, which, when the mortise is not cut through, but simply into, the piece of wood in which it is formed is forced into the tenon, and consequently imparts to it somewhat of the dovetail form, by the mere act of driving the tenon into its place. Robison suggests that, to guard against the liability of the tenon to split beyond the shoulder, the required effect may be better produced by the use of several very thin wedges, which will collectively enlarge the end of the tenon in the necessary degree, than by the employment of a single wedge of greater thickness. This mode of wedging is much employed by ship-carpenters in securing tree-nails, which are the large pegs of wood used in certain cases in lieu of metal fastenings. The subject of naval carpentry will be treated under SHIP-BUILDING.

The series of articles written by Professor Robison for the 'Encyclopædia Britannica' on the science of carpentry, and republished, with notes, in his 'System of Mechanical Philosophy,' form perhaps the most valuable body of information on the subject; though the numerous practical works of Nicholson, by whom the treatise on carpentry in the 'Encyclopædia Metropolitana' was supplied, and Tredgold's 'Elementary Principles of Carpentry,' go much more into details. The nature of the last-mentioned work is noticed under TREDGOLD, THOMAS, in BIOG. DIV. Rondelet's 'Art de Batir,' Colonel Emy's Essay 'sur l'Art de Charpenterie,' and Colonel Ardant's 'Études sur les Combles à grande portée,' may also be advantageously consulted.

CARPET MANUFACTURE. The consumption of carpets in Great Britain up to about the middle of the last century was so very trifling, that, as a manufacture, it was hardly deserving of notice; and although now so essential to our warmth and comfort, a few generations since carpets were only partially used in the mansions of the rich. Only a few manufactories, of which that at Wilton was the most important, existed in different parts of the kingdom; and at Kidderminster, which is now one of the principal seats of the trade, the carpet manufacture did not commence before the early part of the 18th century. At

Halifax, where the trade is very extensive, the introduction of the manufacture was much more recent.

In presenting here some account of the manufacturing processes, it may be well to premise, that in all, or nearly all, kinds of carpets the materials are dyed before they are put into the loom. A very curious and ingenious attempt was made some years since to print the worsteds while in the process of weaving. A patent was taken out, and the object was partially accomplished, but there are so many difficulties to encounter that this plan has not been brought into general use.

The following are the chief kinds now made in Great Britain: Axminster, Venetians of different sorts, Kidderminster or Scotch, British or damask Venetian, Brussels, and Wilton or pile carpeting. These names do not always denote either the present or original place of manufacture. Brussels carpets were introduced into Kidderminster from Tournay in 1745; and we do not know that Venetians were ever made at Venice. Wiltons (which are in fact Brussels carpets) were made on the Continent before they were introduced at Wilton; and what are called Kidderminster are made in the greatest quantities in Scotland or Yorkshire.

Axminster carpets must be included among those which no longer correspond with their name. At Axminster, in Devonshire, a manufactory of expensive carpets was maintained for more than a century; but it has now been abandoned. Axminster carpets (supposing them to be really now made) are usually made in one piece, according to the dimensions of the room for which they are required. The warp or chain is of strong linen, placed perpendicularly between two rolls or beams which turn round and enable the chain to be rolled from off one beam and on to the other as the weaving of the carpet proceeds. Small tufts or bunches of different coloured worsted or woollen are tied to or fastened under the warp; and when one row of these tufts has been completed, the shoot of linen is also thrown in and firmly rammed down. Another row of tufts is then arranged in such a manner as, by a change of the colours, to form a further portion of the pattern. To guide the weaver as to the position of the colours, a small paper design or drawing constantly hangs before him, from which he works. The tedious nature of this process, and the quantity of materials which it consumes, render this kind of carpet very expensive; and few, if any, are now made.

Real Turkey carpets (so called to distinguish them from those Brussels, the patterns of which are made to imitate them) are manufactured in a similar manner to Axminster carpets; they are regularly imported, though not in very large quantities. *Finger* and *Stormont rugs* are also formed with tufts, introduced in a similar way; but the warp or chain is laid horizontally, and a common loom, with its usual appurtenances of treadles, gearing, reed, lathe or batten, &c., is made to assist in the process. In all these carpets the warp and weft, or, as they are called, chain and shoot, which are both of linen, are altogether concealed from the upper surface, the tufts of worsted or woollen being the only part that is visible.

Venetian carpets.—Here the warp or chain, which is of worsted, and generally arranged in stripes of different colours, is alone visible; the shoot, which is of a dark colour and usually black, is concealed between the upper and under surface. By using shoot of different sizes, these carpets are sometimes made to assume the appearance of plaids or checks; and by the arrangement of the treadles, a twilled or dotted appearance is at other times given to them. Venetians are generally used for staircase carpets, but the plaid kind are occasionally used for rooms. Although dots, waves, small figures, and plaids, are sometimes introduced, the general character of Venetian carpets is a simple stripe throughout. They do not come under the head of figured weaving, no machinery but that of the common loom being required for their manufacture. Woollen, linen, and cotton are all used for the shoot.

Kidderminster or Scotch carpets, or, as the Americans more descriptively term them, *in-grain carpets*, are wholly of worsted or woollen; or, as is most common, the chain is of worsted and the shoot of wool. The pattern is formed by the intersection of two or more cloths of different colours; but as these cloths may be woven in stripes of different shades by introducing at intervals shoot of different colours, the carpet is usually made to assume a great variety of colours. Wherever this is the case, however, either the upper or under surface must necessarily have a stripy appearance, and the stripes will be seen running across the carpet. The process of weaving these is somewhat complicated, but we will endeavour to give some idea of its nature, and in our description we will confine ourselves to those in which there are only two cloths. These in fact form nineteen-twentieths of the whole quantity. A few, called three-plys, are made with three cloths, for the North American market; and even four-plys have been attempted. Each cloth is perfect in itself, so that if one cloth were carefully cut away the other would remain perfect, and be in appearance like a very coarse baize. The process of weaving both cloths is carried on at the same time, and in each part of the carpet that cloth is brought to the surface which is required to produce that portion of the pattern. We will suppose the two colours to be blue and white, and that the weaver in proceeding with his work is about to throw in the blue shoot. As in common weaving, he must raise by his treadles and gearing one-half of the blue warp to form the cloth; but he must also raise the whole of the white warp in those portions of the carpet where the pattern requires that the upper surface shall be white; this has to be done by

other machinery, as the quantity so to be raised varies with every shoot. After throwing in the blue shoot he has to prepare for the white one, and it is now necessary for him not only to raise, by the treadles, &c., one half of the white warp, but also by the machinery, the whole of the blue warp, where blue is to form the upper surface. He next proceeds to throw the second blue shoot, and has to raise the other half of the blue warp (that which was raised before being now depressed), and also that part of the white warp which this next portion of the pattern requires for the upper surface. The second blue shoot having been thrown, he proceeds to the second white, and raises the reverse half of the white warp and the whole of the blue warp, where blue is to form the surface; and so on as before. The reader will readily perceive that the back of the carpet will necessarily be of exactly the same pattern as the front, but the colours will be reversed; what is blue on the upper surface will be white on the under, and that which is white above will be blue below. Till about forty years ago, the machinery used to manufacture these carpets was of the most clumsy and complicated nature. A great improvement took place afterwards by the introduction of barrel looms, which were constructed on principles similar to those of the barrel organ or musical box. Each pattern, however, required a change in the barrel, and this process was somewhat tedious and expensive. These looms were therefore shortly superseded by the Jacquard machine, which has brought about a vast improvement in many respects, and enabled the largest and most complicated patterns to be accomplished with the greatest facility, accuracy, and beauty.

British or damask Venetian partake both of the character of Venetian and Kidderminster, though more of the former than the latter. The warp, as in Venetian, is the only part seen, whereas in Kidderminster the shoot forms by far the greatest portion of what is visible. The consumption of British is however small, and perhaps hardly of sufficient importance to render a particular description necessary. The manufacture require machinery similar to that employed in weaving Kidderminsters.

Brussels carpets form by far the most important and increasing portion of the carpet trade. Brussels are composed of linen and worsted, the cloth or reticulated part of the structure being entirely of linen, which is formed into a kind of very coarse sampled cloth, with two threads of linen for the shoot (one above, and the other below the worsted). This will be best explained by a simple diagram of a section of the linen only, the worsted not being shown in this sketch. The

dots represent a transverse section of the shoot; the lines crossing one another are two threads of the warp. Now the worsted is firmly bound in between the upper and under shoot, or, as in this sketch, between the two rows of dots, thus; the dotted lines represent three

ends of the worsted, of which there are usually five, each end differing from the others in colour. These ends, as they are technically termed, are composed of one, two, or three threads of worsted, according to the quality of the carpet: the average number is two. Taking it therefore at two, there will always be ten threads, two each of five colours, bound in between every reticulation of the linen. This gives substance, firmness, and solidity to the mass. A pattern or device is thus produced. We have seen that we have five ends of yarn, each of a different colour, at our disposal in every part of the carpet. All we have to do is to bring to the surface that one of the five colours which is required to form that portion of the pattern, and to form it into a loop projecting above the surface. The section then assumes the appearance of the annexed sketch.

This sketch is in fact a section of a bit of Brussels carpet when complete. The business of drawing the required colours to the surface is performed by a child from ten to fifteen years of age, who is called the drawer, and is placed by the side of the loom for this purpose. Each worsted end is made to pass through a small brass eye, called a mail, to which is attached a very fine cord. This cord passes over a pulley fixed at some height above the loom, and is brought down again by the side of the loom, and fixed to a thick stick or roll near to the ground. Now there are generally 260 ends of each colour in 27 inches, the usual width of the carpet; and with five colours in each place we have 1300 ends: there must therefore be 1300 brass eyes or mails, 1300 cords, and 1300 pulleys to each loom. Such is the usual arrangement; but in some instances two cords attached to different mails are united before they reach the pulley, so that there are 650 pulleys and 650 cords passing over them. The pulleys are arranged with great accuracy and neatness in a frame, technically termed the box, which is placed at a considerable height above the mails. The cords being so numerous present a confused appearance to the spectator; but every one has its proper place, and can, when required, be readily traced by the weaver. Now by pulling the cords

ARTS AND SCI. DIV. VOL. II.

as they hang by the side of the loom, it is evident we shall raise the brass eyes connected with them, and also the worsted ends passing through those eyes; and all that is to be done is to pull such 260 of those cords as will raise the colours required, one end in each place. To accomplish this, a strong thread is made to twine around the cords, and separate those which are required to bring the proper colours to the surface. This thread is called the lash, and one lash is necessary for every set or row of colours that has to be drawn to the surface. These lashes are taken in regular succession till the pattern is complete. The number of lashes must therefore vary with the length of the pattern; in a pattern a yard long there are usually 320 lashes. Such being the arrangement of the mechanism, let us suppose the loom at work, and every thing ready for proceeding. The drawer takes hold of the first lash with his right hand, and gently draws towards him the 260 cords confined by it: this separates them from the others, and he then firmly grasps them with his left hand, and having loosed the lash, he with both hands and the weight of his body draws the cords down. The 260 ends required for the first portion of the pattern being thus raised above the surface, he with his left hand inserts (under the raised ends through the whole width of the carpet) a light wooden board called the sword. The sword is about five inches in width, and being made to stand on its edge, it retains the raised ends about five inches above the surface. The drawer then looses the cords, and prepares for the next lash. When the sword is in, and the required colours thus raised, the weaver using both hands carefully raises any of the ends which stick down by reason of the roughness of the material or otherwise; and having thus formed a clear opening, he inserts the wire under the raised ends throughout the whole width of the carpet. The wire is round, and in diameter about the twelfth part of an inch. After the wire is inserted the sword is withdrawn, and the weaver by means of his treadles and gearing brings above the surface one-half of the linen chain, the other half and the whole of the worsted being depressed. The shuttle with linen shoot is then thrown in. The weaver next raises the reverse half of the linen chain, and the whole of the worsted, the half of the chain before raised being now depressed, and then throws in the second or under shoot. Between throwing the first and second shoot, as well as after the second is thrown, the weaver gives two or three smart blows with the lay or batten, which is very heavy; he thus forces the materials closely together, and gives firmness and solidity to the mass. The weaving of this wire is now complete. The drawer then draws the next lash in rotation, and he and the weaver proceed as before. When a number of the wires have been thus woven in, they may be drawn out, and the carpet is complete. Care must however be taken not to draw out the five or six wires that have been woven last, or the fresh made loops are in danger of being drawn down, and the carpet blemished. It is necessary that each end of worsted should work independently of the others; to accomplish this every end is wound on a separate bobbin, and the bobbins are arranged in frames at the back of the loom, with a small leaden weight or bullet to each bobbin to keep the worsted in a proper degree of tension. This adds greatly to the cumbrous nature of a Brussels loom. The linen chains for Brussels and Wilton, as well as the chains for all other descriptions of carpets, are wound on beams as in other kinds of weaving. The Jacquard machine, before referred to, has been constructed so as to take the place of the drawer, pulleys, cords, and lashes; and this machine is found so convenient that it has been brought into general use for that purpose.

Wilton or pile carpet differs from Brussels only in this; that the wire, instead of being round, is flattened, and has a groove in the upper surface thus ; and, instead of its being drawn out, a sharp knife is drawn along the groove, and the wire is thus liberated. By this means the loops of worsted are all cut through, and the carpet assumes a velvety appearance. The shape of the wire renders it possible to make Wilton or pile carpet of almost any thickness and quality; but this is not the case with Brussels. The manufacture of Brussels carpets was introduced into Wilton soon after its introduction into Kidderminster; the Wilton carpets, being originally a better description of goods were distinguished by the name of cut or Wilton carpets.

In the carpet manufacture, as in most others, novelties of various merit are patented almost every year; but it is unnecessary to notice them in detail. One is for a mode of making Brussels and cut-pile carpets with thick backs, by employing one or more additional sets of weft-threads, tied in by an equal number of warps. Another is for a mode of producing printed warps showing defined figures, by the employment of flat or oval wires. A third is for a kind of carpet made of parti-coloured warps, by applying thick weft to produce two similar corded surfaces, showing the same pattern on both sides of the carpet. Another is for using jute or jute-hemp, instead of common hemp; by a series of boiling, washing, preparing, and spinning processes. At Glasgow, a beautiful kind of carpet is made, as soft as velvet, by throwing in coloured chenille as a shoot, and cutting it into a velvety pile at the surface. One patented kind of carpet, of the velvet texture, is produced thus: In the ordinary mode of making velvet [VELVET], wires are inserted at intervals to assist in forming the loops, and these wires have to be inserted and removed by hand; but in the carpets now under notice, wires are thrown in among the warp-threads, and

removed when the weft is formed, by ingenious mechanism attached to the loom. We have adverted to the attempts made to dye or print carpets in the loom. One such is practised under a patent obtained a few years ago, in order to produce differently-coloured spots, squares, or stripes, by processes independent of the weaving. The warp-threads are arranged side by side in a peculiar frame, so as to form an even horizontal layer; and in that state they are drawn tightly over a printing table, and printed in colours in the usual way. When these threads are applied to weaving, a pattern is produced by a variation of the colours in each thread, in addition to the primary pattern which results from the weaving process.

The power-loom is now largely employed in the carpet manufacture. Mr. Crossley, chief partner of the eminent firm before mentioned, communicated a few important facts on this subject to the Society of Arts in 1856, tending to show that machinery does not always produce the disastrous effects on wages which workmen are so prone to apprehend: "When the Great Exhibition opened in 1851, Messrs. Crossley had no power-loom at work for the carpet-manufacture; they paid 14½d. a yard for weaving velvet carpeting by hand. When they introduced the power-loom, they paid 2½d. a yard for weaving the same goods: it being done, too, much better than when 14½d. was paid. The reduction in price [wages per piece?] was enormous; and yet at this reduction the weavers earned, on an average, twelve per cent. more by power than they had by hand, for the same number of hours' work. A reduction was made in the [price of the] goods in proportion to the saving effected in the weaving; and he (Mr. Crossley) would undertake to say that no one of the men now at work at power-loom weaving would accept hand-loom weaving at 14½d. if it were offered to them, unless their power-loom were taken from them. During the year 1851, Messrs. Crossley paid for wages on an average 150l. a day, or 900l. per week; but during the year 1855, they paid on the average 250l. a day, or 1500l. per week." These comparative figures may, however, relate simply to the extension of business, and not to any higher wages earned per man.

We may briefly notice an apparatus patented for cleansing carpets. The carpet is coiled on a horizontal roller, from which it travels to another roller, by means of a web to which it is attached by metal eyelet holes. A number of beaters or flails are affixed to the surface of a large cylinder above the carpet; by means of tappets, catches, excentrics, and springs, the beaters are made to give a succession of smart blows: the carpet progressing, and the cylinder revolving. Further on are two small cylinders, provided with radial brushes, which brush both sides of the carpet as it passes between them. A crank handle turns the whole mechanism. If the carpet require more cleaning than beating and brushing can give it, it passes over a cylinder heated within, and is rubbed by a brush moistened with scouring liquids.

There are no data from which the extent of the carpet manufactured may be determined. It was supposed by persons engaged in the manufacture, about the year 1835, that the carpet-loom in Great Britain amounted to about 4000; and that the value of carpets made in the year was about one million sterling. In the Board of Trade returns, carpets are combined in the same entry with blankets, flannels, and "mixed woollen stuffs," in such a manner that the amount of the exportation of carpets alone is not shown.

The carpet-weavers have made a laudable attempt to introduce the system of arbitration between masters and men, in the event of trade disputes. To lessen the loss and annoyance of strikes and combinations, several of the masters signed a bond of union, binding themselves to observe an equalisation of wages, and agreeing that no one of them should be allowed to reduce below a certain tariff without the consent of all. The workmen feared at first that this was a masters' combination against them; but gradually a better feeling sprang up. Nearly thirty firms, and more than two thousand workmen, had joined this conciliation-parliament (as it was sometimes called) by the year 1855, chiefly confined to the counties of York and Durham. The masters used to hold a meeting annually, to agree about wages and prices; the workmen were informed of the date and place of meeting; they elected delegates from the several carpet-factories; the masters and the delegates sat in different rooms; each body, or "house," presided over by a chairman, deliberated on the state and prospects of the trade; and the two chairmen were made the means of communication when any propositions were to be made on either side. When Lancashire was agitated by the Preston strike, in 1854, Mr. Henderson, an extensive carpet manufacturer at Durham, wrote a letter in which he showed the effects of arbitration in bringing harmony into the carpet trade, and advocated the policy of a similar proceeding in the cotton manufacture: "Before 1839, victory went at one time with the masters, and at another time with the men. Feelings of injury and mistrust prevailed; and in some instances the struggle became so violent, that the masters had to apply to the police for protection of their lives and properties, both by day and night. I have heard the late Mr. Howard of Leeds, and other large manufacturers, say, that the struggle with their workmen had cost them everything but their lives." Then, of the altered state of things produced by the 'carpet-parliament,' he said, "For the last fifteen years the delegates have only once retired with dissatisfaction, and upon that occasion they prayed the masters to reconsider their verdict; the masters immediately held another

meeting, and arranged the disputed point to the satisfaction of both parties. Since 1839, five strikes have occurred in distant districts; in each of these cases, the masters of the north of England succeeded in effecting a settlement; and while they have obtained the friendship of those distant masters, they have repeatedly received the thanks of the men." The members of the 'lower house' of this curious parliament, the workmen, themselves sent a letter to the Lancashire cotton-spinners during the Preston strike, describing the benefit which had accrued to the carpet-trade, and suggesting conciliation instead of hostility as the best strategy in the cotton-trade also.

CARPOBA'LSAMUM, a kind of volatile aromatic oil, said by Bruce to be furnished by the *Balsamodendron Gileadense*. It is produced by the nuts, which have a fleshy kernel yielding the balsam by simple expression. It should be employed while recent, otherwise it loses its odour and becomes inert.

CARRAGEENIN. Irish moss (*Chondrus crispus*), contains a kind of vegetable jelly or pectin, which is thought to be peculiar, and to which the name carrageenin has been given. It is distinguished from gum by its aqueous solution not being precipitated by alcohol, from starch by giving no blue colour with iodine, from animal jelly by giving no precipitate with tincture of galls, and from pectin by not being precipitated with acetate of lead. Herberger found Irish moss to contain the following ingredients:—

Carrageenin	79.1
Mucus	9.5
Two resins	7
Fatty matter and free acids	
Chlorides of sodium and calcium	
Sulphate of potash	traces.
Iodine or bromine	
Water and loss	10.7

CARRIAGE. [STAGE CARRIAGE.]

CARRIER is one who undertakes for hire the conveyance of goods or passengers for any one who employs him. But a mere carrier of passengers is not a common carrier according to the legal meaning of that term,—this term comprehending those only who convey goods, either by land or water; as, for example, mail contractors; the proprietors of a common stage coach or waggon; the owner or master of a general ship; or a wharfinger who undertakes to convey goods from his wharf in his own lighters. So a railway company are common carriers. And a carrier is held to be a common carrier, and liable as such, although one of the termini of his journey be out of England.

I. *The liability and duties of carriers, as regards the conveyance of passengers.*

By the common law, a carrier of passengers is bound to take care that his carriages and engines, or his coach, harness, and horses are *roadworthy*, that is, sufficiently secure to perform the journey he undertakes; and he will be liable to make compensation to any passenger who is injured in consequence of any insufficiency in this respect. And the fact of an accident happening to a passenger while the carriage in which he was being conveyed, was exclusively under the management of the carrier or his servants, is *prima facie*, sufficient to entitle him to claim compensation against the carrier; so that the burden of proof is thrown upon him to show, that the injury was the result of an *inevitable* accident, and that the goodness of the vehicle and the skill and care of his servants were unimpeachable.

But if the passenger be injured by reason of an accident which was *inevitable*, the carrier will not be liable. For a carrier of passengers does not *warrant* their safe conveyance; but merely undertakes that, as far as human care and foresight can go, he will provide for the same.

II. *The liability of carriers as regards the conveyance of goods.*—Carriers of goods are subjected to a greater degree of responsibility than mere bailees for hire [BAILMENT], and that responsibility is much more extensive than it is in the case of carriers of passengers. By the ancient custom of the realm (which is part of the common law), a common carrier of goods for hire is, in general, not only bound to receive goods tendered to him for carriage, if he have room in his conveyance; but he absolutely insures their safety, against *inevitable accident*; and he is therefore liable for their loss, though he be robbed of them by a force which he could not resist. There are, however, by the common law, three exceptions to this extensive liability: 1st, loss arising from the aggression of the Queen's enemies; 2nd, loss arising from the act of God, such as storm, lightning, or tempest; and 3rd, loss arising from the owner's own fault, for example, by imperfect packing. So a common carrier may limit his responsibility by entering into a special contract with his customer. But in the case of a railway or canal company, the customer will not be bound by any condition or contract which is not in law just and reasonable; and which is not evidenced by being signed by the customer, or by the person who delivers the goods for carriage. (17 & 18 Vic. c. 31, s. 7.)

Formerly, where there was no special contract with the customer, it was the practice of carriers to endeavour, by means of notices, to lessen the extensive liability which the common law cast upon them. The notices they were in the habit of giving usually stated, in substance,

that the carrier would not be responsible for goods above a certain value (generally 5*l.*), unless entered and paid for accordingly. After repeated discussions on the effect of these notices in courts of justice, the carriers succeeded in establishing, that they would not be liable in the above circumstances, if they could *prove* explicitly, in each instance, full knowledge on the part of the person sending the goods, or his agent, of this specific qualification of their general liability. But proof of this fact was in all cases most difficult to adduce; and, to obviate this hardship, the "Carriers Act," 11 Geo. IV., and 1 Will. IV., c. 68, was passed, by which it is enacted that no common carrier by *land* shall be liable for the loss of, or injury to, certain articles, particularly enumerated in the Act, contained in any package which shall have been delivered, either to be carried for hire, or to accompany a passenger, when the value of such article shall exceed the sum of 10*l.*, unless, at the time of the delivery of the package to the carrier, the value and nature of such article shall have been explicitly declared. In such case the carrier may demand an increased rate of charge, a table of which increased rates must be affixed in legible characters in some public and conspicuous part of the receiving office; and all persons sending goods are bound by a notice thus affixed, without further proof of the same having come to their knowledge.

And by the 17 & 18 Vic. c. 31, s. 7, railway and canal companies have been further exempted from liability beyond a limited amount, for damage sustained by horses, cattle, and other animals whilst being carried by them, unless their value be declared at the time they are delivered to the company, and an extra payment made in order to cover the increased risk.

By sec. 3, of the same statute, railway and canal companies are bound to afford all reasonable facilities for receiving, forwarding, and delivering their traffic, without giving any undue or unreasonable preference or advantage in favour of any particular person or kind of traffic, or subjecting any such person or kind of traffic, to any undue or unreasonable prejudice or disadvantage. And by sec. 3, power is given to any one who complains of a breach of the above obligations, to obtain redress by motion in the court of Common Pleas in *England*, or in one of the superior courts in *Dublin*, or, in the Court of Session in *Scotland*.

The liability of carriers *by sea* is modified by the statute 17 & 18 Vic. c. 104, ss. 502—506, whereby the liability of owners of vessels for any damage or loss caused to any goods or merchandise on board the same without the actual fault or privity of the owner, is limited to the value of the vessel and freight. They are also exempted from loss or damage by fire, and from the loss of, or damage to, gold, silver, diamonds, watches, jewels, or precious stones, by reason of their being robbed, secreted, or embezzled, unless the shipper of the goods insert in his bill of lading, or otherwise declare in writing to the master or owner of the vessel, the nature, quality, and value of such articles respectively.

Subject to these exceptions, and to any special contract that may have been made by bill of lading or otherwise, a carrier by sea is liable for all losses, except those occasioned by the act of God, or the queen's enemies; or by the default of the shipper of the goods. And if the ship deviate unnecessarily from her direct course, and the goods are lost or damaged during such deviation, the ship-owner will be liable, even although the loss be occasioned by the act of God or the queen's enemies.

Lien of Carriers.—Upon the general principle, that persons who, at the request of their owners, bestow money or labour on goods, can detain them until their charges in respect thereof are paid, a carrier has a right to detain goods, which have come into his possession as a carrier, until his reasonable charges for the carriage are paid. This in law is called a *particular lien*, in contradiction to a *general lien*, which is the right of retaining goods for the balance of a general account.

(Sir W. Jones on *Bailments*; Selwyn's *Nisi Prius*, title *Carrier*; and Chitty on *Contracts* (by Russell), title *Carrier*.)

CARRONADES are short iron guns, differing from other guns, and from howitzers, only in their dimensions, and in the manner of attaching them to their carriages; which is by a loop underneath, through which a bolt passes, instead of trunnions. They derive their name from the village of Carron, in Stirlingshire, where they were first made.

When fired at point blank, their range is about 150 yards; and, at an elevation of 3 degrees, it varies from 660 to 750 yards; this is much inferior to the range of a long gun, but as they throw shells and heavy shot with great effect within the above limits, they are extremely serviceable on land for breaching ramparts of earth, or for enfilading the faces of works; and at sea, in engagements at close quarters. A flash-rim or enlargement of the bore takes the place of the enlargement of the muzzle, in order to protect the sides and rigging of the ship from the effects of the explosion, and to facilitate the charging.

For the dimensions and weights of carronades, see Spearman's 'British Gunner.'

CARROT (in horticulture), the fleshy root of the *Daucus carota*. This kind of esculent is too well known to require any description. For garden purposes there are three principal varieties; namely, the early horn carrot, a small kind used for the earliest crops; the long orange, or Altringham carrot, a very large kind, for ordinary summer and winter use; and the purple carrot, a French sort, remarkable for

its deep purple colour and unusual sweetness. The latter is not so much known as it deserves to be; the two others are in common use. Several others, among which is a white kind, are mentioned in seedsmen's lists, but they are of little importance.

Nothing can be easier of cultivation than the carrot, provided the soil is light and free from stones; in stiff or rocky soils it is not worth the expense of growing. The seeds are sown at intervals, from the end of February till the beginning of August; they are lightly raked into the soil, having been previously pressed down with the feet. Some persons mix them with damp sand previously to sowing, in order to separate them from each other, and to render them less liable to be blown about by the wind in consequence of their lightness. When they have come up they require no further care than to be hoed to the distance of about six inches apart, and to be kept free from weeds.

CARROT (in agriculture). The large orange carrots, which are the most common for winter provision, are chiefly raised in the fields; and when they can be conveyed to large towns for sale, they are a very profitable crop on light and deep soils. The principal use of the larger field-carrots is as food for cattle. The orange carrot and its varieties are the most common in England, but the large white and yellow carrots, most esteemed on the continent, are now largely cultivated here; though containing probably less saccharine matter, their produce is so much larger that they produce a greater bulk of nutriment on the same ground. The white carrot also will grow on heavier soils than the orange. It is, in Belgium, sown in spring amongst barley, in the same manner as clover usually is; with this difference, that the roots are taken up before winter, and the land may be sown with winter corn the same year. The barley amongst which the white carrots are sown is chiefly winter barley, which is reaped early. As soon as the barley is cut, the land is well harrowed to pull up the stubble, the weeds are carefully taken out, and liquid manure is poured abundantly over the surface. The carrots, which were scarcely visible, and of which the tops were cut off in reaping the barley, now shoot rapidly, and where they grow too thick are thinned out by hoeing. By the end of autumn a good crop of carrots is obtained; and if they are carefully forked up, the ground may be sown with rye without any other preparation. This, however, is not at all to be recommended as an English practice.

When carrots are cultivated in a regular rotation as a principal crop, they are sown in March, or early in April, on land which has been ploughed to a considerable depth before winter, and has had the benefit of the winter's frost. It is not usual to manure the land, but it is best to sow carrots on land which has been abundantly manured either for the preceding crop, or early in the previous autumn. If it be thought necessary to improve the land by manure, it must be done with well-rotted dung, which should be ploughed in very deep. Without this precaution the carrots will be apt to *fork*, as it is called; the root being divided will not swell regularly, and instead of being of a fleshy consistence will become fibrous and hard. The best mode of cultivation is to have the land in a moderately rich state and thoroughly pulverised; to sow the seed in drills, at the distance of a foot or more from row to row: to cover it slightly; and as the plants appear, to water them with diluted urine or the drainings of dunghills; to destroy all weeds carefully by the hand and the hoe, and to thin the plants in the rows to the distance of 5 or 6 inches or more, according to the richness and depth of the soil. Although the carrot, when it grows most vigorously, does not throw out any considerable fibres from the upper part of the root, and appears to draw its chief nourishment from its lower end, yet it is a great advantage to keep the ground stirred and light between the rows; for exceedingly minute horizontal fibres shoot out to a considerable distance from the sides of the root, and tend much to increase its size. The seed of the carrot has numerous hooked hairs which spring from the husk, and make the seeds adhere together; on this account carrot seed is usually mixed with earth or sand, and well rubbed in the hand before it is sown. Five or six pounds of seed are needed for an acre if the seed is drilled; it requires more than this if sown broad-cast. In this last way very heavy crops are sometimes obtained, but the expense of weeding the carrots by hand is so great that the drilled crops, besides being more certain, are more profitable. Too much care cannot be taken in selecting good seed. The finest and largest carrots should alone be chosen to plant out in spring to produce seed. They will throw out vigorous stems bearing numerous umbels, which, as the florets fade and the seeds ripen, contract into the form of a bird's nest. Those who are curious in the choice of the seed take only such seeds as grow on the outer border of the umbel. The tops of the carrots are frequently cut off before they arrive at the full size, as food for cattle and sheep, who are very fond of it; but this is not a judicious plan; as the loss in the growth of the roots from being deprived of the leaves is much greater than the value of the tops as food, especially if they are cut off repeatedly, which is sometimes done when fodder is scarce. When the plants begin to wither, and the outer leaves to droop to the ground, the tops may be safely mown, and the roots left in the ground. They have then acquired their full growth, and will remain sound in the earth till there is danger from the winter's frost.

The best method of taking up the carrots to store them for winter use is by means of three-pronged forks, such as are used in digging asparagus beds. They should be rather blunt at the point and sides

of the prongs, and be stuck into the ground vertically by the side of the rows; by pressing down the handle the carrots come up without injury. It costs 18s. to 20s. per acre to dig up a good crop. The plough is sometimes used after the coulter has been removed; but with all the care of the ploughman, the plough and the horses will cut and bruise many of the finest carrots. Carrots may be kept all winter in dry cellars, if they are protected against the frost. The more common way is to store them with straw in long trenches, like beet. [BEET.] The produce of cattle-carrots on good light land may be 10 to 15 tons per acre, and they do not impoverish the land so much as potatoes. From twenty to forty pounds of carrots, with oats, is a sufficient allowance for a hard-working horse for twenty-four hours. Where hay is scarce, it is a most economical substitute.

In Brittany they have an ingenious method of getting several acres of land trenched by the plough and the spade at the same time, for the growth of parsnips and carrots. The different farmers join to bring as many labourers together as will dig out a furrow as rapidly as the plough can draw it: they divide the whole length of the field equally among them. As soon as the plough has made a furrow, the men trench the bottom of it with their spades nine or ten inches deep, throwing the earth over the furrow slice last turned; on the return of the plough the next slice is turned into the deep trench and immediately covered by the spades as before. Thus an acre is readily trenched in one day to the depth of fifteen or eighteen inches, and all the weeds are buried: carrot or parsnip seed is sown on the surface and slightly harrowed in. The common mode of ploughing in stitches is the most convenient for this operation, as each man will only have to move from one side of the stitch to the other immediately after the plough has passed. But a second plough following in the furrow made by the first will do the work equally well, and at less expense.

If carrots are cut in pieces and steamed, they become more nutritious, and the expressed juice made to ferment affords by distillation a very good and wholesome spirit. Sugar may also be extracted; but the carrot is inferior to the beet in this respect.

CARTE-BLANCHE (literally, white card) is a paper signed, and, if necessary, sealed by the party against whom it is to be used, but (with the exception of the signature and seal) blank; in order that it may be filled up with such conditions as the party to whom it is delivered may prescribe. Thus, when Charles I. was about to be condemned, his son, Prince Charles, sent to the Parliament a blank paper signed and sealed by himself, in order that they might dictate their own terms for saving his father's life.

The term is often used to express an unrestricted authority delegated by one man to another; thus a general is said to have *carte-blanche* from his sovereign when he has leave to carry on the war at his own discretion.

CARTHAMIN ($C_{25}H_{16}O_{11}$). The florets of the *safflower*, or *Carthamus tinctorius*, a plant of the natural order *Compositae*, contain two colouring matters: one, extracted by water, is yellow, and quite unimportant; the other, insoluble in water, is red, and is called *carthamin*, or *carthamic acid*. It is best obtained pure by first washing the florets in weak vinegar, to extract the yellow colouring matter, and then digesting them in a dilute solution of carbonate of soda, which dissolves out the carthamin. From this solution it may be precipitated on flocks of cotton wool, placed for that purpose in the liquid, by acetic acid or lemon-juice. From these, after washing, it may be obtained by re-digestion in dilute carbonate of soda solution, and re-precipitation by acid. Washed and dried, it presents the appearance of a brilliant green amorphous powder, of metallic lustre. In thin layers, by transmitted light, it appears a rich red-purple. When moist, it browns turmeric paper. It is insoluble in water or acids, slightly so in ether, and more so in alcohol, yielding a beautiful purple liquid. It is very soluble in alkalies.

Safflower is largely used as a dye, on account of the carthamin it contains. The colour is very beautiful, but fugitive.

Pink saucers, sold at colour-shops, for dyeing silk, &c., are prepared with carthamin.

Vegetable rouge is usually carthamin mixed with powdered French chalk.

Chinese card rouge is a small folded card, apparently covered with carthamate of soda, colourless at first, but, rubbed on the skin, is then decomposed by the acid secretions, producing a beautiful rosy tint.

CARTHUSIANS. The Carthusian monks were a branch of the Benedictines, whose rule, with the addition of a great many austerities, they followed. Bruno, who was born at Cologne in Germany, first instituted the order at Chartreux, in the diocese of Grenoble in France, about A.D. 1080; whence the monasteries of the Order, instead of Chartreux-houses, were in England corruptly called *Charter-houses*. The rule of the Carthusians, which is said to have been confirmed by Pope Alexander III. as early as 1174, was the most strict of any of the religious orders, the monks never eating flesh, and being obliged to fast on bread, water, and salt one day in every week: nor were they permitted to go out of the bounds of their monasteries, except their priors and procurators, or proctors, and they only upon the necessary affairs of the respective house.

The Carthusians were brought into England in 1180 or 1181, by King Henry II., almost as early as their establishment at Grenoble,

and had their first house at Witham, in Somersetshire. [BENEDICTINES.]

CARTOON, from *carta*, paper, *cartone*, large paper, Ital.; a word used by artists to signify the full-sized drawings or studies made in chalks, or in body-colour (*tempera*, as it is called in Italy), preparatory to executing any great work either in oil-colour or fresco. Cartoons are also made when the design is to be copied in tapestry.

The preparation for making cartoons is very simple: Several sheets of paper are pasted together at the edges, and then strained on a frame of the size required. Sometimes the surface is *primed*; that is, washed with a general colour or ground, but more frequently the paper is left in its natural state, and the drawing is made either in chalks or, as above stated, in *distemper*. When only two colours are used, as black and white, or brown and white, it is called "in *chiaroscuro*," that is, light and shade. The cartoon being finished, it is transferred either by laying it upon the canvas on which the picture is to be painted, and tracing the lines through with a hard point (powdered charcoal, or black lead, or chalk, being first rubbed on the back of it, or on paper placed between it and the canvas); or lines are drawn over it perpendicularly and horizontally at equal distances, and exactly corresponding lines or squares being made on the canvas, the parts of the cartoon are carefully copied into them, and the colouring is then commenced. The injury which the drawing of lines over it might do to the cartoon may be avoided by straining threads across it from pins at the required distances round the frame. In *fresco* painting the plaster on which the work is to be executed must be wet, and only a small portion can therefore be completed at a time; the transfer of the cartoon is effected here in small compartments, either by tracing as much as the artist means to finish, or by pricking the lines through.

The great masters seldom commenced any extensive picture without first making studies or cartoons in *chiaroscuro*. Many of those by Raffaele, Andrea Mantegna, Domenichino, the Carracci, and others, remain to attest the laborious diligence and care with which their great works were accomplished. By this means the composition, drawing, expression, and light and shade, were all perfected before the colouring of the picture was attempted, and as these may be said to constitute the highest qualities of art, the schools that chiefly attended to them, namely, the Roman, Florentine, and Bolognese, are eminently distinguished for their *grand style*.

The finest specimens of cartoons that are known are those executed by Raffaele d'Urbino, for Leo X. in 1615-16, and which were sent to Flanders, to be copied in tapestry, in two sets. One was intended for the decoration of the pontifical apartments in the Vatican; the other as a present from the pope to Henry VIII. of England. The tapestries (only shadows of Raffaele's exquisite designs) were finished (the first set being hung up for the first time in the Sistine Chapel on the 26th of December, 1519), and one set is now in Rome. The other was in England till the death of Charles I., when it was purchased and carried to Spain by the Spanish ambassador. A few years ago this set was purchased from the family of the Duke of Alva, by Mr. Tupper the British consul, who brought them to London and publicly exhibited them; but failing to find a purchaser they were carried back to the Continent, and eventually, at the suggestion of Chevalier Bunsen, purchased for the Berlin Museum.

The cartoons, originally twenty-five in number, were left neglected at the tapestry works at Arras, in the Netherlands, and most of them seem to have been lost or destroyed. A few, however, escaped this fate, and seven are now at Hampton Court. Their history, even since their arrival in England, is eventful. They were bought in Flanders by Rubens for King Charles I., with a view to their serving as patterns for the tapestry works at Mortlake. They were cut in slips and packed away in boxes; but they do not appear to have been removed from Whitehall. At the dispersion and sale of the royal collection the cartoons were secured to the country by purchase, by Cromwell's particular command: at which time, we are told, the triumphs of Julius Caesar by Andrea Mantegna (still preserved at Hampton Court) were valued at 2000*l.*, while the cartoons of Raffaele were estimated at only 300*l.* In the reign of Charles II. they were again consigned to neglect. It is indeed said by Richardson, that Charles was only prevented by the representations of the Earl of Danby, from selling them to Louis XIV., who was anxious to purchase them for his tapestry works. Charles II. re-established the works at Mortlake, and the cartoons were sent there, and there were left unregarded. When William III. wished to have them hung up they were found to be seriously injured, but the king directed Henry Cooke, a painter of some reputation in his day, to repair them and to strain them on canvas. William also employed Wren to design a gallery at Hampton Court for their reception, in which they remained till 1764, when George III. removed them to Buckingham Palace; and in 1787 to Windsor Castle. They were, in 1814, again removed to Hampton Court, where they now are.

The cartoons represent the following striking subjects from the New Testament:—

Paul preaching at Athens.

The death of Ananias.

Elymas the sorcerer struck with blindness.

Christ delivering the keys to St. Peter.

The sacrifice at Lystra.

The Apostles healing the sick in the Temple.

The miraculous draught of fishes.

This is not the place to speak at length of the merits of these grand works. It will be enough to say that they are universally admitted to be, as designs, the very finest of Raffaele's works, and that they rank among the very noblest productions of the painter's art. The compositions are in the highest degree masterly, and the stories intended to be illustrated are told with the greatest perspicuity. In the details they exhibit every variety of character and expression: the mild sublimity of our Saviour, the quiet dignity of the Apostles, admiration, doubt, surprise, pain, fear, down to the careless innocence of childhood, are all portrayed with a master's hand. The women are almost perfect delineations of grand female beauty, and the children, wherever they are introduced, are models of infantine grace and simplicity. In the arrangement of drapery Raffaele was unrivalled, and the cartoons offer the finest examples of excellence in this respect. These exquisite works can scarcely be too often or too carefully studied by those who desire to form a pure and elevated taste in design.

These cartoons have been engraved by Dorigny, Audran, and Holloway, and in a bold but effective manner (so as to be published at a very moderate price), by John Burnet; but during the summer of 1858 two series of photographs of the cartoons on an unusually large scale, and separate studies of single figures, heads, &c., were made by Messrs. Caldessi and Montecchi, and Mr. Thurston Thomson, which afford copies of the cartoons infinitely preferable to the best engravings for the purpose of study. There are engravings of a greater number of the cartoons than those in the English collection, some of which are taken from the tapestries; of others it is believed the originals no longer exist. Five from tapestries represent the Adoration of the Kings—Christ appearing to Mary Magdalen—the Disciples at Emmaus—the Murder of the Innocents—the Ascension. Others are described by Fea, in his 'Descrizione di Roma,' and Somereau, a French artist, engraved them, with the whole series, in 4to.

Two very fine cartoons in black chalk, by Annibale Carracci, are now in the National Gallery; they were formerly in the collection of the Earl of Ellesmere, who presented them to the nation. They are studies for parts of the decoration of the Farnese Palace in Rome, and offer examples of the free and large style of design which characterised this artist's pencil. Some of the cartoons prepared by English artists for the fresco decorations of the New Palace at Westminster, have been placed in Hampton Court.

CARTRIDGE, a cylindrical case, containing a charge of gunpowder or shot, or of powder and ball, for fire-arms. Those used for military purposes, to facilitate the loading of muskets, carbines, and pistols, are formed of a strong hard paper manufactured for the purpose, called cartridge-paper, and are styled ball or blank cartridges according as they contain both powder and ball or powder only; while the larger cartridges for cannon and mortars, which always consist of powder only, are usually cased with flannel, though sometimes paper, paste-board, tin, or even wood is employed. The North Americans, during their last war with England, are said to have employed very thin sheets of lead, resembling those used for lining tea-chests, for this purpose. The advantage of such a substance is, that it obviates the danger of burning particles of the cartridge-case which remain in the piece after it is fired,—an accident which is liable to occur when flannel is used, and which may be productive of the most fearful consequences.

Wire cartridges, for containing a charge of small shot without powder, are manufactured for sporting purposes. The author of the article 'Shooting,' in the seventh edition of the 'Encyclopædia Britannica,' states that they were invented in 1828 by Mr. Jenour, but that they were not brought to perfection until nearly ten years later, owing chiefly to the difficulty of regulating the precise time for the dispersion of the shot. Eley's wire cartridges have been brought, by successive improvements, to a high degree of efficiency, and are made of various qualities, according to the distance at which the charge is required to take effect. Wire cartridges consist of an inner case of wire network, inclosed in a thin paper case, to the outer end of which a wadding is attached. The shot, with which it is usual to mix bone-dust or some other substance to fill up the interstices, is put within this case, which is rammed down upon the charge of powder. When the gun is fired, the paper case is torn to pieces as soon as the cartridge leaves the gun, and the shot immediately begins to quit the cartridge by passing through the meshes of the wire net work, which is carried forward with the charge until it is quite empty, when it falls to the ground. By this contrivance the leading of the gun is avoided, and the recoil produced by the discharge is lessened, the charge leaving the barrel like a bullet. The shots are also carried so much more closely than when loose, that lighter charges, and consequently a lighter gun, may be used; much time is saved in loading, especially as no separate wadding is required; and, as the cartridge has no inclination to move before it is impelled by the explosion of the powder, the danger arising from the accidental shifting or rising of loose charges is avoided. Greener, in his work entitled 'The Gun; or, a Treatise on the various descriptions of small Fire-arms,' which was published before wire cartridges had been brought to their present state of comparative perfection, suggests the use of a case of felt, made much thicker at the bottom than at the sides, as a substitute for wire.

In the 'Transactions of the Society of Arts,' vol. xlv. pp. 106, 107,

is a description, illustrated by figures, of a machine invented by Mr. Caffin for filling cartridges, in which two cylindrical cases, each of which will contain the proper charge for one cartridge, open at both ends and tapering a little at the lower end, are so mounted that by moving a handle each may be brought alternately under a hopper, from which it receives a supply of powder, and then over an aperture in a plate upon which it moves, through which the charge escapes by a conducting channel into the paper case of the cartridge. With one of these machines one boy is able to deliver 12,500 measures of powder in a day, supplying the hopper himself.

The cartridge employed for the rifles of the present day is made with three pieces of paper: 1st, a stiff paper is rolled round the mandrill, a wooden cylinder of the size of the cartridge; 2nd, an envelope of thin paper is wound round this and folded into the hollow at the end of the mandrill, and pressed in with a "former," which has a conical point of the shape of the bullet; 3rd, the bullet is put with its point into this cavity, and the whole wound round with another layer of thin paper, or outer envelope, and fastened under the bullet. The mandrill being then withdrawn, the powder-case is filled with powder, and the thin outer cases squeezed just above the stiff paper, and the end laid down with a slight twist. The bullet is now covered with only one paper, while the powder has three; the paper over the bullet is lubricated with bees'-wax and tallow, and the cartridge is complete. In using these cartridges, the top being torn off, and the powder poured into the barrel, the cartridge is reversed, and the ball being entered nearly to its head in the barrel, a smart twist tears off the stiff powder-case easily at the place where it joins the thin covering of the bullet, which is then left with its point free, and with a cover of lubricated paper round it. Another method of making cartridges has lately been adopted in the Royal Arsenal at Woolwich; in this process the whole cartridge is made in one bag. A series of hollow mandrills, with small holes all over their surface, are fixed into, and the hollows communicate with, a circular tube, from which the air is exhausted by a steam-engine. Over these mandrills canvas bags are placed, and the circular tube is lowered into a bath of paper pulp, so as just to cover the mandrills which project downwards. The air being then exhausted, the water of the pulp is drawn through the canvas and holes in the mandrill, and leaves a certain amount of pulp adhering to the canvas bag; the part to contain the powder being made thicker by larger holes in the mandrills at that place than where the bullet comes. The circular pipe with the mandrills being then removed, is fixed to a steam pipe, and hot steam passed back through the canvas bags, which drying the pulp, the paper bags are easily removed.

CARTS AND WAGGONS. The drag-cart without wheels, which is used in some mountainous districts, is one of the simplest contrivances for transporting heavy weights. It consists of two strong poles, from twelve to fifteen feet long, connected by cross pieces fixed at right angles to them, by morticing or pinning, so that the poles may be two or three feet apart. About eighteen inches of the poles project beyond the lowest cross piece, the ends resting on the ground. The other ends of the poles form the shafts for the horse to draw by. The load is placed on the cross pieces, over which boards are sometimes nailed, for the purpose of carrying stones, or such things as might fall through between the cross bars: it then resembles the body of a cart taken off the wheels. The horse bears one end of the drag-cart by a strap over his back, and draws it by means of a common cart-collar or breast-strap. This vehicle is extremely useful in steep and rough descents, especially to draw stones from quarries, and can be made of rough poles at little or no expense. Pieces of hard wood fixed under the ends of the poles, and renewed as they wear out, will prevent the ends of the drag-cart from wearing away, and will allow it to slide along more easily.

The Irish car (*fig. 2*) may be considered as the next step towards a better construction. This car consists of a bed or platform and two shafts. The wheels, in the simplest form, are round discs of wood made by nailing planks to a thickness of two or three inches over each other, so that the fibres of the wood in one plank shall lie at right angles to those in the other; they are then sawn into the form of a circle, and an iron tire put on the circumference. Two of these discs are fixed on a square axle of wood at the distance of three or four feet from each other. The ends of the axle, which project three or four inches beyond the wheels, are then rounded in the form of cylinders of two or three inches diameter. To the under part of the bed of the cart two blocks of wood are fixed, which raise it so that the wheels may go under the cart, and in these blocks are two round holes to admit the ends of the axle. Two strong nails or iron pins driven obliquely into the blocks after the wheels are put under, serve to prevent the axle from slipping out. A little grease on the ends of the axle diminishes the friction, and prevents the disagreeable grating of the wood when the wheels turn round. This is the simple old Irish car. The only difference in the construction of the most improved modern cars is the substitution of neat wheels, and iron axles for those described above, and a railing or box fixed on the platform. The great simplicity of the Irish car, its easy construction, and the convenience of the platform to place the load on, are its greatest recommendations. It is well adapted to narrow mountainous roads; and the wheels being quite under the bed, there is less danger when two carts meet,

or among trees and rocks; especially when one man has the charge of several cars, or the horses are permitted to find their way home by their own sagacity. There is a considerable inconvenience in turning, as the wheels do not turn separately, and one of them must be dragged

Fig 1.

Fig. 2.

Fig. 3.

along, while the other forms the centre round which the car turns. This description relates wholly to the agricultural and quarry and general goods cars. In the improved passenger or *jaunting* cars, the wheels are made to turn separately on the axles, by which this inconvenience is obviated. The wheels of the carriages on railroads are constructed on the principle of those of the Irish car. The axle turns with the wheels in a bush or box fixed to the carriage. This gives greater facility for keeping a constant supply of oil to the box by means of a fixed reservoir; and the carriage not being required to turn round, no inconvenience arises. Some of the remarkable circumstances connected with the establishment of Mr. Bianconi's car traffic in Ireland will be found noticed under STAGE CARRIAGE.

The common cart differs from the car chiefly in the circumstance that the body rests on a fixed axle between the wheels, which turn upon the axle by means of boxes in the centre of the naves. The simplest cart is that used by carriers in France and Germany. (Figs. 1 and 3.) It consists of two strong poles of ash or beech, resembling those of the drag-cart described above, but stronger, and fashioned with more care, so as to have considerable strength at the place where they rest on the axle-tree. One end forms the shafts, and the whole is equally poised on the axle. The wheels are often nearly six feet in diameter, and narrow at the tire; they are slightly dished, but run nearly perpendicularly to the road. On these carts very great weights are transported, so as to require five or six horses to draw them. On paved roads they may have some advantages; but there is much loss of power when many horses draw at length; and the horse in the shafts is often much distressed by the weight suddenly thrown on his back, and by the striking of the shafts against his sides. It would be impossible for the shaft-horse to bear the weight in going down steep descents, or to keep his footing up steep hills (however well the cart may be poised), if it were not for an ingenious contrivance, by which the load is shifted at pleasure backwards or forwards on the axle. In ascending, the centre of gravity is moved nearer to the horse, and, in descending, farther back, so as to be always nearly perpendicularly over the axle. Another contrivance is a mode of retarding the motion of the wheels in descending. This is done by forcing a pole against the outer rim of the wheel, one end being fixed to the shafts of the cart, and the other drawn, by means of a rope, tightly against the side of the wheel, which rubs hard against it. The object is thus obtained; but the wheels are soon worn away, and the pole requires to be carefully looked to, because it often wears through and breaks, when the whole load comes suddenly against the horse and throws him down. Another equally rude and extremely noisy mode is to cut a tough branch, a little longer than the distance between the wheels, and place it horizontally between the spokes, so that it projects about an inch or two on each side. The wheel, in turning round, bends the branch until the ends escape from one spoke and strike the next; thus a constant retardation of the wheel takes place at the expense of the spokes, which are soon worn out. A better contrivance is a piece of wood or iron in the form of a small segment of a circle, of the same diameter as that of the wheel, which is made to press more or less on the rim of the wheels by means of a lever to which it is attached. It is regulated by a

screw turned by a winch, which gives the exact pressure requisite to overcome the downward tendency of the load, and may be so nicely adjusted that it requires only a slight exertion in the horse to draw the cart down. By some of these contrivances many of the inconveniences arising from the use of carts are obviated. Where the roads are level and hard, waggons are much to be preferred to carts; but in hilly countries and bad roads, carts have many advantages.

For agricultural purposes, various kinds of carts have been invented. The capacious tumbril for carting earth and dung, with broad wheels to prevent their sinking in soft ground, is too generally known to require description. The best constructed carts have iron axles with the ends or arms turned smooth, and very slightly conical. The boxes in the naves of the wheels, which receive the arms, are made of cast iron, and ground smooth, so as to require only a small quantity of grease or oil to make the wheels run easily, without allowing any play or side motion. It is usual to give the axle a bend at the place where it enters the wheel, by which means the planes of the wheels are made to diverge from each other and give more room for the body of the cart. But this is decidedly wrong. It is clearly proved that the draught is least when the arms are quite horizontal, and if the wheels are slightly dished, that is, if the spokes are driven into the nave obliquely so as to throw the rim a little beyond the perpendicular, the lower spokes in each wheel will slightly diverge, and give greater steadiness to the whole. When the axle is bent, the rim of a broad-wheeled cart must be slightly conical, in order that it may rest flat on the ground; and it is easily proved that in this case the load is dragged on the ground at every revolution, along a space equal to the difference between the greater and lesser circumference of the rim of the wheel, giving unnecessary work to the horses, and greatly injuring the roads. The light Scotch cart, drawn by one horse, is justly considered as the most advantageous for transporting earth, lime, or dung, especially in hilly countries. It is low and short, so that the horse draws very near the centre of gravity; and there is little power lost by obliquity. The loads may be so adjusted as to bear more or less on the horse, according to the declivity; and experience has proved that more weight can be transported by a given number of horses, when each is attached to a single Scotch cart, than when three or four draw together, except it be on very level and hard roads, or when the horses move at a quick pace. The objection made to single-horse carts, that each requires a man to drive it, is obviated in Scotland, where the horses are trained to follow each other, and one man can attend to several carts and horses. In England this is not allowed on the roads for fear of accidents.

The Scotch cart is made to carry hay and straw by means of a light frame, which is laid on it, and projects over the body and the wheels in every direction. At harvest it is found that this arrangement enables the farmer to collect the sheaves of corn and carry them to the stack or barn more rapidly than could be done by a waggon. A good horse will walk faster, when he has a load on his back, than he could do if he were merely drawing; and although this exertion, if continued long, would exhaust him, he soon recovers his breath, if he has only been urged for a short distance, and then returns with a light empty cart.

To avoid the weight resting on the back of the horse, carts have been invented with three wheels, the small additional wheel being made to turn in front. It is only in the case of moving earth down a declivity, and returning with the empty cart, that it has any advantage over the two-wheeled cart; it is therefore seldom used for general purposes. The additional wheel adds to the weight which the horse has to draw, and is an incumbrance in a ploughed field.

The addition of springs to carts and waggons is a very great improvement, and should be adopted in every case where they are much used on the roads. The additional weight and cost of the springs are greatly overbalanced by their advantage: they lessen the draught, and, by preventing jolting and shaking, add to the durability of the vehicles. Where a light active kind of horse is used which can trot with a moderate load, it will be found that there is a great advantage in occasionally increasing the pace at which empty carts and waggons are made to move. In Holland and Flanders, the waggons are always driven at a smart trot when going empty to the field in harvest or hay-making, and much valuable time is saved by this means.

For a notice of the remarkable modern improvements in agricultural carts, enabling them to supersede in great measure the heavy waggons, see AGRICULTURAL IMPLEMENTS. The chief vehicles for passenger traffic, such as hackney-coaches, cabriolets, stage-coaches, and Irish jaunting-cars, and the legislative arrangements relating to them, are treated under STAGE CARRIAGES. The manufacture of coaches generally is described under COACH MAKING, and that of wheels under WHEEL.

CARUACROL. [CARAWAY, OIL OF.]

CARUEN. [CARAWAY, OIL OF.]

CARUM CARUI (*Common Caraways*) — *Medical Properties of.* This umbelliferous plant is indigenous in most parts of the south of Europe, where its roots are used in the same way as those of the parsnip and carrot, and its fruits, incorrectly termed seeds, are collected as aromatic stimulants, for a variety of purposes. It is cultivated in England, chiefly in Essex, for the fruit alone; but much of what is used in this country is imported from Germany, where it is in exten-

sive use to form a liqueur. The fruit is too familiarly known to require description; but to secure it in perfection it must be ripe, brown, not green, and when rubbed or bruised it should emit a strong characteristic odour. This depends on the presence of a volatile oil, which exists in the proportion of 4 to 5 per cent. It is obtained and purified by repeated distillation. The official preparations are the oleum carui, aqua, and spiritus. For preparing the aqua two modes are given in the 'Pharm. London, 1851,' the latter of which only is ever followed: a portion of the oil dissolved, or diffused through the menstruum, is a speedy mode of obtaining the object. The oil is sometimes given dropped on sugar. The powers of caraway are similar to those of dill [*ANETHUM GRAVEOLENS*], and the observations there made on the use and abuse of this carminative are applicable here.

CARVENE. [CARAWAY, OIL OF.]

CARVING, the art of forming any hard materials into a proposed shape or figure by means of sharp instruments. It is usually understood to refer exclusively to works in ivory or wood, to distinguish it from carving in marble or stone, which comes under the term *sculpture*, except in the cutting of architectural ornaments, which is regarded as carving rather than sculpture. Carving in metals is called *chasing*.

The ancients used ivory to a great extent in works of art, and its union with gold, called by the Greeks *chryselephantine* sculpture, was adopted by the greatest artists. The colossal statue of the Olympian Jupiter at Elis, by Phidias, was one of the most celebrated examples of this combination. Ivory carving was practised to a considerable extent by Byzantine artists between the 5th and the 12th centuries: and again by the carvers of the 13th to the 15th centuries. The Italian renaissance carvers (from the 15th to the early part of the 17th century) executed many works of exceeding beauty—as Fiammingo, whose carvings of children have never been equalled; Pronner, of Nurmberg; Van Obstal, of Antwerp, and others. In later times carving in ivory has been for the most part confined to smaller objects, as small figures, reliefs, enrichments of flowers, fruit, and other devices on vases and cups, and such objects of general use. The instruments used for carving in ivory are very similar to those employed in working in marble, consisting of chisels of different sizes, saws, rasps, and files; the polishing is effected, as in marble, by friction.

Wood of almost every description was a favourite material for carving among the ancients; and, after clay, was doubtless, from the facility of cutting it, the first substance used for imitative art. Some figures of very remote antiquity found in the tombs in Egypt are of sycamore. In Greece many of the statues of the gods were of wood; and all those attributed to the first Dædalus were of that material, from which circumstance indeed wooden figures were called *Δαίδαλα*, or Dædalian. Wood seems to have been used for sculpture long after more valuable and durable materials were employed. Pliny and Pausanias describe many of these works, and mention the varieties of wood of which they were made. Among them were the oak, ebony, fir, cedar, box, citron, cypress, beech, fig, myrtle, olive, palm, poplar, vine, &c. &c.

For a long period in modern times there was a great demand for fine wood-carvings, and wherever Gothic architecture flourished there existed very skilful carvers. The elaborately worked Gothic screens, choir-seats, and desks, in most of our cathedrals and colleges, as well as in similar edifices in France, Germany, and Flanders, canopies, frames for doors and pictures, cabinets, and indeed every description of furniture, are evidence of the extent to which it was employed, and of the skill of the artists. Many of these performances display indeed more ability in the workmanship than good taste in the design, being, where figures are introduced, chiefly of grotesque and not unfrequently indelicate subjects. But there are very many specimens of chaste design, as well as careful execution.

One of the most eminent modern carvers in wood was Grinling Gibbons, a native of England. He was much employed by Charles II., particularly at Windsor Castle and Hampton Court. In London the choir of St. Paul's may be instanced as a work of this artist. Many of his best performances are at the country residences of some of the English nobility; the specimens at Chatsworth and at Petworth are admirable imitations of nature. In our own day the art has been revived, and there are at present in this country some excellent carvers in wood. Much of the hand-cut carving at the New Palace of Westminster is very beautifully executed; and in the present year (1859) Mr. W. G. Rogers, to whom the revival of the art of wood-carving in England is to a great measure due, has carved in oak, in a very beautiful manner, the entire fittings of a church (that of St. Michael's, Cornhill), being the first complete work of the kind probably executed in England since the decline of Gothic architecture. Architectural sculpture, or carving in stone, has also been of late practised with great spirit and feeling, and many such works now deserve to take rank as works of fine rather than mechanical art, as they used to be considered a few years back.

The woods preferred by modern carvers are the pear, lime, American pine, maple, oak, and box: and the tools they employ are round hollow chisels called gouges; others with an angular extremity called from the shape V tools; flat chisels of various sizes, and files. A mallet is sometimes used, but pressure, or a sharp blow from the bottom or heel of the hand, is generally preferred. The surface is

cleaned and polished with sand-papers of different qualities, by pumice-stone, and by friction.

Wood Carving by Machinery.—Within the last few years machinery has been applied to the carving of wood. The display of true artistic feeling in carving is only possible where each specimen is made by hand, and is regarded as a work of art by its producer; but where a great number of duplicate copies is needed, the work becomes a sort of manufacture, to which machinery may be applied. In Jordan's carving machinery the wood has movement given to it, while the tools remain nearly stationary. A pattern of the work to be carved is first modelled by the artist, and afterwards copied by the machine in wood with perfect accuracy, and in such a manner that two or three copies are made simultaneously; the carvings thus prepared by the machine are then sent back to the artist, who introduces by hand the finishing touches. A very large amount of the carving in the new Houses of Parliament has been effected by this machine. The more delicate work for the same building, requiring hand-processes, as already mentioned, was entrusted to Mr. Rogers.

About the year 1846 Mr. Pratt patented a carving-machine, which was based on another patent machine, invented by Mr. Irving, for preparing the materials for inlaying. According to a description given of it before the Institute of British architects, Mr. Pratt's machine combines the principle of the lathe, the drill, and the pantograph. The material on which the design is to be carved is fixed on a table which turns on a centre. The tool, acting in the manner of a centre-bit, is attached to an arm, also working on a centre, and is made to revolve with great velocity. Guided by a pattern of cast-iron, the tool, by a double movement of the arm and the table, can be made to pass through any combination of curves, drilling out the material as it passes over it. The lines of the design are determined by the iron pattern, and the depth and form of the sinking by the shape and position of the tool; and if a double moulding is required, two patterns and two tools and a double operation are necessary. The tool and its position at the end of the arm being once adapted to the section of the moulding to be produced, the rest is purely mechanical; the workman guides the tool with one hand, and the table with the other, and the design comes out with great rapidity. The tool revolves three thousand times in a minute, and the wood is cut away in the form of very fine fragments, like sawdust, leaving a smooth surface behind it. The machine will cut stone with nearly the same facility as wood.

A kind of imitative carving was introduced a few years ago, in which a hot iron is employed instead of a cutting tool. An iron mould is prepared corresponding to the pattern to be produced, and this mould, being heated to redness, is applied with great force to the surface of a piece of damped wood; this process is repeated until the required form is produced, by burning away the surface of the wood. The char is then removed, and any requisite undercutting is done by hand. When finished, the work has somewhat the appearance of old oak, and the surface may be brought to a high polish.

CARVOLE. [CARAWAY, OIL OF.]

CARYATIDES (*Karyatides*), female figures employed in architecture in place of columns, like Atlantes and Telamones. Vitruvius (b. 1, c. 1) attributes the origin of caryatid figures to the circumstance of the inhabitants of Caryæ, a city of Peloponnesus, taking part with the Persians during the invasion of Xerxes, and their consequent punishment: the men were slain, and the women carried into captivity; and their ignominy was perpetuated by the employment of figures, similar to the women of Caryæ, in place of columns. This story however, is hardly worth relating. It has sometimes been conjectured that these figures represent the virgins who celebrated the worship of Diana; while others have thought that they represent Athenian virgins carrying on their heads the sacred vessels used in religious ceremonies. The use of caryatid figures is far more ancient than the date of the story told by Vitruvius; like many other forms of art, they were no doubt derived by the Greeks from Egypt. [ATLANTES.]

Six beautiful caryatid figures were employed in the Pandrosion, one of the buildings on the acropolis of Athens. The northern portico of the Pandrosion had six Ionic columns, four in front, and one on each flank: the southern portico was supported by six caryatid figures, four in front, and one on each flank. They were placed upon a basement, and supported an enriched entablature. (Stuart's 'Athens,' vol. ii. Plates.) One of the figures is now in the British Museum among the Elgin collection. The execution of this figure is extremely fine; its height is seven feet nine inches. Three of the caryatides remain in their original position, but greatly mutilated.

At the sides of the New Pancras church, London, and at the east end, are two projecting wings with four caryatid figures in each. The whole is an imitation of the Pandrosion; but the figures are very ill executed, and it need hardly be remarked how very incongruous such figures appear as parts of a Christian church. These excrescences form the entrance to the places of sepulture under the church.

Another caryatid of a much later style of art, representing a female of heroic size, of a grave and dignified appearance, is in the third Græco-Roman saloon in the British Museum, and being nearly perfect shows better than the former the character of these figures, though inferior to it as a work of art. This figure is draped with the diploidion or double tunic, with a kind of peplus fastened on the

shoulders by fibulae, and is adorned with earrings, necklaces, and bracelets. On her head she carries a modium, which originally supported part of the entablature of a portico. It was found with three similar figures in 1766, on the site of a temple, supposed from the

[Caryatid figure from the Pandrosion, now in the British Museum.]

CARYOPHYLLIC ACID, *Eugenic acid* ($C_{10}H_{12}O_4$). The volatile essential oils of cloves, pimento, and cinnamon leaf, are chiefly composed of a hydrocarbon isomeric with oil of turpentine, and an oxygenated oily body, caryophyllic acid.

When either of these oils is mixed with caustic potash or soda and submitted to distillation, the hydrocarbon is volatilised and the caryophyllic acid remains in combination with the alkali, forming a butyraceous crystalline mass. This residue distilled with sulphuric acid, yields the caryophyllic acid in a nearly pure state.

Caryophyllic acid is a colourless oily liquid, in taste and smell much resembling oil of cloves. It gives an acid reaction with litmus paper. Its specific gravity is 1.079; boiling point, 436° Fahr.; vapour density, 6.4. It rapidly absorbs oxygen from the air, becoming resinified. When required quite pure it must be redistilled in an atmosphere of carbonic acid.

Caryophyllic acid forms salts with most of the bases. Brought into contact with caustic potash, soda, ammonia, baryta, strontia, or lime, it unites to form crystalline compounds containing an equivalent of basic metal in the place of an equivalent of hydrogen. The soluble caryophyllates give, with solution of acetate of lead, a light yellow precipitate; with sulphate of copper, light-blue; with protosulphate of iron, lilac; and with persulphate of iron, red changing to violet and blue.

Some interesting derivatives of caryophyllic or eugenic acid have been obtained by M. Cahours, by reaction with the chlorine compounds of organic acid radicals. The following neutral substances have been thus obtained, hydrochloric acid being produced at the same time:—

Benz-eugenyl	$C_{34}H_{40}O_6$
Tolu-eugenyl	$C_{36}H_{42}O_6$
Cum-eugenyl	$C_{40}H_{48}O_6$

CARYOPHYLLIN ($C_{20}H_{28}O_2$). A solid, white crystalline substance found in cloves. It crystallises from a strong alcoholic infusion, or may be precipitated by the addition of water to an ethereal infusion. Resin, with which it is generally contaminated, may be removed by

occurrence of a figure of Bacchus to have been dedicated to that deity, near the Via Appia, a few miles south-east from Rome; it was purchased by Mr. Townley, with the rest of whose collection it was bought by the Government in 1808.

[Caryatid, from the Townley Collection, now in the British Museum.]

boiling with caustic soda or ammonia. It has the appearance of silky needles, which, if pure, sublime at a high temperature without decomposition. Caryophyllin is freely soluble in hot alcohol or ether, from which solution the greater part crystallises out on cooling. It is insoluble in water. Caustic alkalies and strong acids dissolve without decomposing it. With concentrated sulphuric acid it gives a red solution which decomposes when boiled. Nitric acid converts it into a resinous substance.

CARYOPHYLLUS AROMATICUS, the clove-tree (in Botany), is an evergreen small tree, belonging to the natural order *Myrtaceae*, with opposite, ovate-lanceolate, shining, leathery, stalked leaves, and a short terminal cluster of flowers. The flower-stalks are green; the calyx consists of a brownish-red cylindrical tube, terminated by four ovate teeth; there are four small greenish concave petals, and a large cluster of yellow stamens. The fruit is an oblong one-seeded purple-berry, crowned by the persistent teeth of the calyx. All the parts are, as in other true myrtaceous plants, covered with dots containing the essential oil peculiar to the species. The clove is a native of the Moluccas, whence it has been carried to all the other tropical parts of the world. Captain Owen's people found it apparently wild even upon Fernando Po, whither it had been probably transported by the Portuguese. The cloves of the spice shops are the flower-buds of this plant, gathered before they open, and dried in the sun; the round ball at their ends is the corolla inclosing the stamens; the quadrangular part below is the tube of the calyx; and the four teeth are the divisions of the calyx. The name *clove* is a corruption of the French word *clou*, a nail, a name that has been suggested by the resemblance of the dried clove to such a thing. The aromatic stimulating effects of cloves are well known. For a good account of their introduction to Europe, consumption, &c., see 'Botanical Magazine,' vol. liv. t. 2750. By some modern botanists, the genus *Caryophyllus* is reduced to *Eugenia*.

The *Caryophyllus aromaticus* grows naturally in New Guinea and the Molucca islands, from which last exclusively Europe was supplied for a long time. About 1769, the French introduced it into the Isle of France, of Bourbon, and the Sechelles, and in 1771 into Guiana. In 1798, the cultivation of this tree was extended to Sumatra, and

very lately it has been introduced into Brazil. A tree 12 years old will yield from 5 to 20 pounds of cloves annually; when older it may

yield about 60 pounds, after which the quantity again diminishes. But as a single stem may live 150 years, it may furnish during that time 1100 pounds of cloves. Each clove is about half an inch in length. The external colour is dark brown, appearing as if covered with dust or little warts, with a somewhat fatty coating. When broken across, the appearance is decidedly oily, and oil quickly exudes from the exposed broken surfaces. The odour is strong and peculiar, but agreeable; the taste aromatic and burning.

Several varieties of cloves are found in the market. The difference of colour is attributed to the different season of the year when the gathering was made. 1st. Soft cloves, called also the Dutch Company's cloves; these have generally been distilled once, and have but a faint odour and taste. 2nd. Dry cloves, which are mostly distinguished according to their place of growth. The English Company's cloves, which are the finest sort, are of a large size, and of a bright reddish-brown colour. The Amboyna are probably the soft Dutch cloves. The Bourbon cloves are small; those of Guiana are still smaller; these two last-named sorts are chiefly used to mix with the former and finer kinds. Analysed by Trommsdorff, 1000 parts yielded of—

Volatile oil	180 parts
Scarcely soluble extractive	40
Gum	130
Resin	60
Tannin	130
Lignine	280
Water	180

The volatile oil seems to be of two kinds, respectively termed: light oil of cloves, a hydro-carbon, isomeric with oil of turpentine; heavy oil of cloves, called also clove acid, caryophyllic acid, and eugenic acid. It is this oil which has an acid re-action, and combines with alkaline bases. It is essential to be acquainted with it and its properties, as in some analyses its presence gives rise to a supposition of opium being in the stomach. Eugenol is the stearopten of oil of cloves. Caryophyllin is clove sub-resin. Clove tannin has some slight points of difference from other kinds of tannin.

By distillation a thickish oil is obtained, which is at first colourless, but by time becomes yellow and brown. Its odour partakes strongly of that of cloves; its taste is very fiery and aromatic; it re-acts as an acid. In time there separates from it a stearopten or clove-camphor, called *caryophyllin*. This principle may be procured in greatest quantity from the English Company's cloves; more sparingly from the Bourbon and Cayenne cloves; in some it appears to be altogether wanting. Owing to the presence of so much oil, cloves cannot be powdered without adding some gum or sugar during the process.

Cloves are employed in medicine, and also more extensively for culinary purposes. When received into the stomach they are powerfully stimulant, and promote digestion when taken along with food which is insipid or difficult of digestion. Though the action is generally limited to the stomach, yet if taken in excess, or the use very long

continued, it extends to the brain, causing giddiness and other inconveniences. Cloves may be given in powder, along with gum, in very moderate doses; but the infusion is a preferable form. Infusion of cloves is a grateful gargle to persons salivated by mercury. Either alone, or when made the vehicle for carbonate of ammonia, nothing so effectually and safely removes that feeling of coldness and weight about the stomach experienced by hysterical or gouty persons, and renders it unnecessary to have recourse to alcoholic stimulants, such as brandy, which is too frequently employed under such circumstances. Oil of cloves is used to drop into decayed teeth, and also is given along with many purgative and other medicines to correct their griping tendencies.

The fruit of the clove, called the mother clove, possesses little odour or acrimony; but when preserved with sugar, it forms a good condiment to be eaten at dessert by persons with weak digestion. What is called the royal clove is merely a monstrous variety of that above described.

The buds of the *Calyptanthes aromatica* are employed in Brazil as a substitute for those of the *Caryophyllus aromaticus*. The botanical portion of this article was accidentally omitted in the NAT. HIST. Div., and has therefore been supplied here.

CASCARILLA BARK. Whatever doubts may have existed respecting the plants which yielded this bark, or its course to Europe, seem now entirely dissipated by the researches of Dr. Wm. Freeman Daniell, staff-surgeon, while stationed in the Bahama Islands, and the botanical commentaries of Mr. J. J. Bennett, secretary to the Linnæan Society. It appears that three distinct species of the genus *Croton*, yield cascarilla bark. Of these, two are natives exclusively of the Bahama Islands, one common to the Bahama Islands and Jamaica. Of these is—

1. *Croton Eluteria*, Bennett; synonymous with *Eleuteria providentiae*, folio cordato subtus argenteo; Sweet bark, seu cortex beneolens, of Petiver's collection, 4 n. 276; *Eleutheria*, Linn. Hort. Cliff. p. 486; *Clusia Eluteria*, L. 'Sp. Plant.' ed. 1, p. 1042 (excl. synon. omn. præter Hort. Cliff.); *Clusia Eluteria*, s. Cascarilla, Woodv. 'Med. Bot.' p. 633 t. 223, f. 2. Grows in the Bahama Islands; Catesby, Dean, Dr. W. F. Daniell.

2. *Croton Cascarilla*, Bennett; synonymous with *Ricinoides elæagni folio*, Plum. Spec. 20, Icon. p. 236, t. 240, f. 1, Catesby 'Cardl.' vol. ii. t. 46; *Clusia Cascarilla*, L. 'Sp. Plant.' ed. 1, p. 1042. Grows in the Bahama Islands, Catesby; Providence, Dr. W. F. Daniell.

3. *Croton lineare*, Bennett; synonymous with the plant in Sloane's 'Hist. of Jamaica,' i. p. 133, t. 86, f. 1; *Croton fruticulosum*, Browne 'Jam.' p. 347; *Clusia Cascarilla*, Linn. 'Amœn. Acad.' v., p. 411, and the specimen so named in the 'Herbarium' of Linn.; *Croton lineare*, Jacq. 'Amer.' p. 256, t. 162, f. 4, Pict. p. 124, t. 263, f. 80; and with *Croton Cascarilla*, Woodv. 'Med. Bot.' p. 629, t. 222. It grows in Jamaica (Sloane, Houston, Wright), and in the Bahama Islands, Catesby, Daniell.

4. *Croton Sloanei*, Bennett; synonymous with the plant in Sloane, 'Jamaica,' ii., p. 30, t. 174, f. 2; *Clusia Eluteria*, Linn. 'Amœn. Acad.' v., p. 411, Linn. 'Herb.'; *Croton Eluteria*, Swartz, 'Flor. Ind. Occid.' p. 1183, Wright in Med. Journ. viii. p. 3, Woodv., 'Med. Bot.' p. 634, t. 223, f. 1 (very bad fig.), Hayne, Arzneigen. xiv. t. A native of Jamaica; assigned by most writers as the source of cascarilla; probably yields none of the bark of British commerce, though some of the continental cascarilla may come from it, as well as *Croton micans*, L., another Jamaica species. Swartz's plant is the "wild rosemary" of the West Indies. The plant assigned by the late Prof. Don as the source of cascarilla, is the *Croton Pseudo-China Schlechtendal*, a native of Mexico, and in the shops of Jalapa is known as the *Quina Cluca*, or *Copalchi*. Some of this has been brought to Hamburg as the *Cascarilla de Trinidad*. It corresponds in appearance with the Ash Jaen, or (corruptly Ten) bark, the produce of some species of *Cinchona*, to the barks of all which the term *Cascarilla* or *little bark* is given in South America, leading to much confusion, and lending countenance to the idea that cascarilla bark comes from Lima.

There is a corky copalchi bark yielded probably by *Croton sulcerus*, Humb.; but it has none of the aromatic taste of true cascarilla, though in burning it gives out an aromatic odour. It comes from Chili, under the name of *Natri*. (Pereira, 'Materia Med.')

The bark occurs in pieces from one to four inches long, which are tubular or overlapping; externally covered with a cuticle, which easily peels off, so that the liber or bark is often exposed, in which case it feels soft and cork-like. The colour externally is yellowish, ash-gray, or varying to reddish brown; this last colour is mostly owing to the presence of lichens. The surface is also marked by irregular, deep, longitudinal furrows. The inner surface is a dirty or rusty brown colour. Odour faintly aromatic; taste bitter, not unpleasant, and stimulating. No alkaloid has been detected in it, but it possesses much volatile oil; one pound of bark yields one drachm and a half of volatile oil. This bark is sometimes mixed with the cinchona barks, being called gray-fever bark; a substitution in no respect hurtful.

The action of cascarilla on the human system depends partly on its bitter principle, and partly on its volatile oil: by the former it approaches the pure bitters; by the latter, the aromatic stimulants. It possesses this great advantage over almost all other tonic medicines, that it is more easily digested by the stomach, when no other affection

of that organ exists than debility and inactivity. This property can only be imparted to other tonics by the addition of aromatics, while it is possessed naturally by this spontaneous combination. In the treatment of pure indigestion from weakness of the stomach and alimentary canal, cascarilla merits the preference. It is likewise of much utility in the treatment of intermittent and nervous fevers, and chronic diarrhoea dependent upon debility; provided no inflammatory condition of the mucous membranes of the stomach or intestines co-exists.

Powder, or a cold infusion, is the best mode of administration; decoction is objectionable from dissipating the volatile oil. From its pleasant aromatic odour it constitutes an ingredient in *fumigating pastiles*. On its first introduction into England, it was used to mix with tobacco, a use to which it is still put in Germany; but a large quantity of it so used is productive of giddiness and stupefaction—not free from danger.

For the botanical details above cited, see 'Journal of Proceedings of Linnaean Society of London,' vol. iv. p. 29, 1st July, 1859.

CASCARILLIN. The bitter principle of cascarilla, the bark of a euphorbiaceous tree, the *Croton eleuteria*. It crystallises in colourless prismatic needles, and sometimes in hexagonal plates. It is bitter to the taste but inodorous, very slightly soluble in water, but soluble in alcohol and ether. Sulphuric acid dissolves it with the production of a very intense red colour: on the addition of water a precipitate is formed which communicates a green colour to the solution. Hydrochloric acid also dissolves cascarilla with a violet tint, the addition of a little water changes this to blue, whilst a larger quantity produces a green coloration. The composition of cascarillin is unknown.

CASE, ACTION UPON THE, is one of the forms of action by which a remedy for certain civil injuries might be obtained. It owes its origin to the Statute of Westminster the Second; and derives its name from the circumstance that in the old form of the writ or process, which formed the commencement of the suit, the particulars of the wrong complained of, or the *case*, were set out in detail with nearly the same precision as in a declaration. (Blackst., 'Comm.,' Mr. Kerr's ed., vol. iii. p. 129, n.)

CASE, IN GRAMMAR. [ABLATIVE CASE.]

CASE-HARDENING is an important process in the steel manufacture; or, rather, it is the imparting of a steel surface to iron goods, such as workmen's tools, fenders, fire-arms, keys, and cheap cutlery. The goods, when finished, except polishing, are exposed to a high heat in contact with certain other substances. The most usual substance is animal or vegetable charcoal, in a pulverised state. Sometimes the agent consists of a composition of horn, bay salt, and white wine vinegar; and other kinds are occasionally used. If the process be well conducted a thin film on the surface of the iron has been converted into steel, and acquires a degree of hardness sufficient to resist the action of an ordinary file. The relation which this process bears to the manufacture of steel proper will be seen in a later article. [STEEL.]

CASE-SHOT are bullets contained in a cylindrical tin canister, or in a spherical shell of iron, which are discharged from a piece of ordnance. The first of these kinds of case burst immediately on leaving the gun, and the bullets commence diverging almost immediately in all directions, and soon lose all regularity of motion; and though they do great execution among the troops of an enemy within the limits of their effective range, that range, which does not exceed 500 yards, is in general of too small an extent. The divergency of the balls is said to be less when they are put into the case in tiers than when thrown in at random; and it is further lessened when the bottom of the case is formed of a strong plate of iron.

The spherical case-shot (the second kind above mentioned), which are also called Shrapnell shells from the name of the inventor, are fired like common shells, and the length of the fuse being properly regulated, they only burst at the required spot; and the liberated bullets and the fragments of the shell spreading out and going with the velocity communicated to them by the gun, may be made to take full effect in a column of an enemy's troops at 800 or 1200 yards distance, or whatever is the effective range of the particular gun. For further particulars, see SHRAPNELL SHELL.

CASEIC ACID. [CHEESE.]

CASEIN, the characteristic nitrogenous constituent of milk. It forms the greater part of cheese. It has already been noticed [ALBUMEN] as one of the albuminoid or protein group of substances, and is closely allied to the other members. It contains no phosphorus. According to Mulder, it is composed of—

Carbon	54.2
Hydrogen	7.2
Oxygen	22.4
Nitrogen	15.8
Sulphur	0.4
	100.0

It has been asserted that casein exists in two states,—one in which it is soluble in water, and another in which it is insoluble. Soluble casein, however, has never been obtained free from alkali; and it is more than probable that, as in milk, it is the alkali that renders it soluble.

Casein is best prepared by gently warming fresh milk with a small

quantity of dilute sulphuric acid, well washing the coagulum that separates, dissolving in a sufficient amount of concentrated solution of carbonate of soda, and setting aside for some time exposed to a temperature of about 70° Fahr., in order that fatty matter may rise to the surface and remain behind when the alkaline solution of casein is removed by a siphon. Re-precipitation by acid and re-solution in alkali must be gone through several times, and the final curdy precipitate well washed with water to remove the last portions of acid, and with alcohol and ether to separate traces of fat.

Moist casein reddens litmus paper. It may be readily dissolved in water containing a small quantity of alkali or alkaline carbonate. From this solution it is re-precipitated by an acid or by strong alcohol. Albumen, it will be remembered, is not precipitated by acetic acid, which re-action serves to distinguish casein from that substance, added to which, solution of casein is not, like albumen, coagulated by heat.

The most interesting property of casein is the facility with which it is coagulated by the mucous membrane of the fourth stomach (*rennet-bag*) of the calf, or rather by the soluble matter (*rennet*) produced by the slow decomposition of that membrane. A small piece of the dried stomach allowed to digest a short time in a little water, yields a liquor which, added to two or three thousand times its volume of warm milk, soon causes perfect coagulation, the mixture popularly known as *curds and whey* resulting. This is, as is well known, one of the first steps in the process of cheese-making. Liebig's explanation of this reaction is, that the membrane altered by exposure to the air and moisture acts at the slightly elevated temperature as a ferment, transforming the milk-sugar into lactic acid, which, after the same manner as other acids, precipitates the casein. This theory is supported by the fact, that the mixture, after coagulation, always presents an acid re-action; but at the same time it must be borne in mind that the same effect of curdling occurs at a little higher temperature, when a sufficient amount of carbonate of soda has been added to produce a permanent alkaline re-action. Further investigation will no doubt throw full light on this remarkable change.

Solution of casein affects polarised light in the same manner as albumen, and in its deportment with chemical re-agents much resembles that substance. With lime it forms an insoluble and very stable compound used in encaustic painting. It admits of being easily moulded, and receives and retains colours exceedingly well.

CASEMATE, a vault of stone or brick-work, generally built in the thickness of the rampart of a fortress for the reception of artillery which is to fire through embrasures pierced for the purpose in the front of the vault.

The smallness of the flanks in the ancient bastions, and consequently the insufficiency of the fire from their parapets, gave rise to the invention of casemates which, being formed under those parapets, augmented the means of defending the ditches without rendering any change necessary in the size of the works. Casemates so situated exist in the flanks of the Tower bastions, in places fortified according to the second system of Vauban; and at New Brisach they are formed both in the flanks of the bastions and in those of the intermediate curtain.

Buildings of this nature appear to have been executed as early as the 16th century, for they are mentioned by the Italian engineers of that age; and, as it was foreseen that the smoke arising from the discharge of artillery in the vaults might, after a short time, render them untenable, Castriotto recommended that only cross-bows or engines for throwing stones should be placed in them.

In the works of Vauban casemates have also been constructed under the parapets in the flanks of the ravelins and of their reduits, for the purpose of defending the ditch and of co-operating with the flanks of the bastions in opposing the construction of the besieger's counter-battery whose situation is indicated at H [Fig. 1, BASTION].

Besides the supposed inconvenience on account of the smoke, casemates in such situations, their front walls being unavoidably weakened by being pierced with embrasures, are liable to be destroyed in a short time by the direct fire from the counter-batteries, when the roofs, in falling, may bring down with them the parapet above. To avoid this evil, engineers have proposed that the casemates in the flank of a bastion should be covered by the *tenaille* [P, fig. 1, BASTION]; in which case a fire of shells is to be directed over the *tenaille* when it is intended to oppose the enemy in the formation of his lodgments.

A difference of opinion has existed concerning the impediment which might be produced by the smoke in the service of the guns; and in the year 1800 an experiment was made by the French engineers in order to determine the question, in the casemates of the Tower bastions at New Brisach, by firing 60 rounds from two pieces in half an hour. Each of these casemates has a perforation in the front wall, above the embrasure, and an ordinary chimney in the wall opposite the front; and during the firing the door between the casemates was kept open. No considerable inconvenience was experienced by the officers who were present; and as the service of guns in casemates so situated can never be required for a longer time, it seems evident that the apprehensions entertained on this subject are without foundation.

Similar experiments have been made in the casemates of Fort Ricasoli at Malta, and the smoke went off very freely; but these, besides having an air-hole in the front wall, are open towards the rear. The casemates proposed by Bousmard to be built in the flanks of his *tenailles* are ventilated in the same manner; and those exhibited in the system of

Carnot are entirely open both in front and rear; the mortars or howitzers being masked by a wall over which the line of fire is to be directed.

The term casemate is also applied to the shell-proof vaults of stone or brick constructed in fortresses to protect the troops, provisions, and ammunition. These are usually formed on the fronts which are least exposed to the enemy, and within the masses of the ramparts either of the bastions or curtains in order that they may be sufficiently protected from the effect of shells falling on them; attention should also be paid in constructing them that their interiors be dry and well ventilated. For the latter purpose, they may have perforations in the front walls; and to render them waterproof, the upper surface of the vault is usually covered with cement. That surface is in the form of two inclined planes meeting in a ridge over the crown, and the ridge as well as the gutter between every two casemates, is covered with lead. Drains are formed in these gutters to carry off the rain; to facilitate the descent of which into them, courses of dry bricks or beds of gravel are laid on the exteriors of the vaults; over these is a covering of clay and earth, terminating above in a level surface. (Colonel Pasley's 'Elementary Fortification,' vol. ii. p. 367.) It was from the humidity as well as from the crowded state of the casemates at St. Philip's Fort in Minorca, and the consequent sickness among the troops, that the governor of that post was compelled to surrender it when it was besieged by the Spaniards in 1782.

When casemates are built for troops, they should be 16 feet wide, in order to allow room for a double row of beds with a passage along the middle; and on the hances of the vault (the weakest part) the brick work should be about three feet thick. Those at Gibraltar are from 16 to 18 feet wide in the interior, and 16 feet high from the floor to the crown of the arch, which is semicircular, and they are from 40 to 100 feet long; some of them have air-holes in front, with chimneys through the roof, and the back walls have doors and windows which may be kept open while the firing is continued. The vaults of the casemates on the western heights at Dover are parabolical; the whole interior height is 17 feet, the breadth 18 feet, and the rise of the curve is 9 feet from the springing courses.

CASH-CREDIT. [BANK; BANKING.]

CASHMERE, or CACHEMERE, a peculiar textile fabric formed of the fine downy wool found about the roots of the hair of the Tibet goat. [GOAT, NATURAL HISTORY DIVISION.] It is so called from the original seat of the manufacture, in the valley of Cashmere, in the north-west of India. Shawls of exceedingly delicate quality are the principal articles manufactured of this material; but a cloth woven in imitation of them is also made. There has been some discussion among persons engaged in the cloth manufacture whether the two names *Cassimere* and *Kerseymere* are merely two forms of spelling the same name, or whether they relate to two distinct kinds of fabric. It is now supposed that *Cassimere* was a corruption of Cashmere, and was the name given to the cloth woven in imitation of Cashmere shawls; whereas *Kerseymere* took its name from the village of Kersey in Suffolk.

An interesting description of the manufacture of Cashmere or Kashmir shawls is given in Vigne's 'Travels in Kashmir,' from which it appears that the thread is dipped in rice-water before weaving, by which process it is made stronger, the stiffness thus imparted being subsequently removed by washing. Of the actual process of weaving we find no satisfactory account. The needle is occasionally used in the production of the patterns; but Vigne observes, that "if the pattern be worked with the needle the shawl is far inferior, in every respect, to those in which the pattern is woven in," and that "an excellent pair (the shawls being always made in pairs) of the former description may be purchased in Kashmir for 150 rupees (about 10*l.*), whereas an equally good pair of the *usuleh* (the real), or the latter kind, could not be procured for less than 700 or 800 rupees." The process is exceedingly slow, the weaving of a pair of shawls, or, as some writers have it, of a single shawl, often employing three men with a clumsy old-fashioned loom for a period of six months; and owing to the numerous heavy duties charged upon the shawls between leaving the loom and reaching a purchaser in this country, the price of real Cashmere shawls of the best quality is very high. They have frequently been sold in London at from 100 to 400 guineas each; and in one instance, when the import duty, which has since been greatly reduced, amounted to 80 per cent. on the value, as much as 500 guineas was demanded for a single shawl.

The peculiar softness of Cashmere shawls appears to be in some degree attributable to the process of washing to which they are subjected after weaving. "The best water for this use," observes Vigne, "is found in the canal between the lake and the floodgates at the Drogjun." "Some ruins, in large limestone blocks, are lying on the washing-place, and in one of these is a round hole, about a foot and a half in diameter and a foot in depth; in this the shawl is placed, and, water being poured over it, it is stamped on by the naked feet for about five minutes, and then taken into the canal, by a man standing in the water: one end is gathered up in his hand, and the shawl swung round and beaten with great force upon a flat stone, being dipped into the canal between every three and four strokes." The shawls, i. e. coloured, are then dried in the shade, as the hot sun would injure the colours, and about ten days afterwards the same process is repeated

though for a less time. White shawls, however, after being treated in like manner, are spread in the sun, and bleached by sprinkling water upon them; and the alternate washing and beating, and drying and bleaching in the sun, are repeated three times, soap being occasionally used in the second washing and stamping. "There is something in the water of the canal," observes the same authority, "which certainly communicates to the shawl a softness which cannot be given to those manufactured at any place in the plains of Hindustan." "At the same time," he adds, "those made in Paris or at Norwich would be, I think, as soft, were it not for the greater closeness of texture, consequent on their being made by a machine instead of the hand." "For the same reason," he proceeds, "it is well known that the calico made in India is much softer, and is much more durable, than that made in England." The water is readily found near the surface of the ground, is bad tasted, and, Vigne believes, brackish. Old shawls that require cleaning, and sometimes also new ones, are washed by means of the freshly-gathered root of a parasitical plant called *kritz*. A pound of this is bruised and mixed with about three pints of water, to which is added a piece of pigeon's dung, equal in size to a turkey's egg, beaten up in about an equal quantity of water. The shawl is saturated with this liquor, stamped upon, washed with the hand, and then steeped in the canal. By a peculiar process, a fine pale yellow colour is given to the shawls by the fumes of sulphur. A cloth called *siling* is manufactured from the shawl wool in Yarkund and China, which resembles a coarse English kerseymere in texture.

Various attempts have been made to naturalise the Cashmere shawl goat in this and other European countries, but as the peculiarities of its wool appear to be dependent upon climate, the perfect success of any such attempt is problematical. The wool itself has also been imported as a raw material; and the late Dr. Ure gave an account of the various plans adopted in France for working both the imported wool and that produced in France from a breed of Tibet goats imported in 1819, into shawls in imitation of those of Cashmere, in which plans the Jacquard loom has been employed to great advantage. In the shawl manufacture in Scotland, attempts have more than once been made to introduce either the real Cashmere wool itself or some effective substitute for it. In the year 1830, at which time the weaving of shawls from Cashmere yarn imported from France had become an important branch of manufacture, a premium of 300*l.* was offered by the Board of Trustees for the Encouragement of Arts and Manufactures in Scotland, to the person who should first establish the spinning of Cashmere wool upon the French principle. In consequence of this offer, Captain C. S. Cochrane devoted himself to the subject, and having succeeded, after some difficulty, in obtaining a knowledge of the secret, he patented the plan, and subsequently sold his patent to the Messrs. Holdsworth of Glasgow, who established the manufacture successfully, and obtained the offered reward in 1832. Judging from an experiment recently (1858) made with the alpaca, there is a possibility that the Cashmere goat may one day be introduced in Australia.

The various woven goods called "Cashmeres," like "alpacas" and "merinos," too frequently have little or no claim to the designation; they are imitations, ingenious enough if they were but called by their right names.

CASK-MAKING. [COOPERAGE.]

CASSATION, "the reversal of a judicial sentence," is a French law word, derived from "cassare," which, in the barbarous Latin of the lower ages, was synonymous with "irritum reddere," in which sense, as Ducange shows, it frequently occurs in ancient royal edicts; thus we find it in a charter of Offa, king of the Mercians, A.D. 790; and in the 'Life of Canute, king of the Obrodita,' c. 4, s. 17, it also appears as a technical term, signifying to cancel or annul; and was applied as well to the annulling of private deeds, such as wills, as of municipal charters and corporate statutes, see Ducange, sub verb. *cassare* (2). But the word is of still older date than the documents Ducange refers to; for it appears in several places in the Theodosian Code, in the sense of annulling and abrogating.

The origin of this institution, like most of those which date from the middle ages, is involved in much obscurity, but the different stages through which it went may be briefly noticed.

1. During the whole period when trial by battle was in vogue, there was but one mode of appeal against the decisions of a judge, being that of challenging such judge to single combat; whilst a direct appeal to the suzerain, or feudal chief, was allowed in one case only, that of a denial of a hearing, but—

2. When the system of judicial combats, or trial by battle, was abolished by Saint Louis (A.D. 1260), a change with regard to appeals was introduced, and not only was permission then given to the unsuccessful party to appeal to a superior judge, but he was enabled to demand from the judge or judges by whom his cause had in the first instance been heard, an amendment of his or their decision; hence, in process of time, not only was the power of appeal affirmed, but the mode became altered until—

3. At the commencement of the 14th century, the hearing of appeals and the power of judging "en dernier ressort," was lost by the royal judges, and became vested in the parliament, from whose decisions there was no appeal; though—

4. Provision had been made and sanctioned by royal authority, between the years 1302 and 1344, to meet the case of errors or ambi-

guities in these parliamentary decisions. The process by which this was done, known at first under the name of "lettres de grâce de dire contre les arrêts," and afterwards under that of "propositions d'erreur," was ruled by the ordonnance of 1344, which established the principle that the decisions of the parliament could only be reviewed by a "proposition d'erreur," or by special letters to be referred to and heard by the "conseil du roi," and then to be returned to the parliament, by whom the errors, if established, were to be amended.

5. From this period then dates, and to this ordonnance is to be ascribed, the form of appeal which eventually arrived at the process adopted by the cour de cassation. Sufficient has been said on the subject of the origin of this system, nor is it necessary to dwell upon the alterations that took place in consequence of abuses, alterations effected by the vigour of Olivier and L'Hôpital, and framed into the ordonnance of 1579.

By the order of procedure established under Louis XIV., in 1667, two modes of setting aside the decisions of the parliament were finally adopted; one was by "requête civile," which annulled a decision and restored the parties to their previous condition, in consequence of either fraud or legal mistakes being discovered in the proceedings; and the other was by "cassation," in consequence of a violation of either the principle or form of the law in the decision of the court. In the latter case the cause was tried anew in a council consisting of the chancellor, the four secretaries of state, the council of state, and the maîtres de requête. The national assembly, in November, 1790, having abolished this system, and established a distinct, permanent, and independent court, called Tribunal de Cassation, by a sénatus consultum of the 20 Floréal, year XII., declared the precise position, and marked the limits, of the new tribunal, which afterwards received its full organisation under Napoleon, and has ever since continued under the name of Cour de Cassation. It is the highest court of France, receiving appeals from all other courts, and may be defined in the words of the Constitutional Act of the 22nd Frimaire, year VIII., as "a tribunal which pronounces on applications to quash the judgments given by tribunals of last resort. It does not go into the merits, but quashes judgments in cases where the forms of procedure have been violated, or which are founded on erroneous interpretation of the law, sending back the merits to the tribunal which is to take cognizance of them." (Acts 65 and 66.) It consists of forty-eight members, who, by the charter of Louis XVIII., are appointed by the sovereign, but retain their places for life. The court has its president, although on certain occasions the keeper of the seals, or minister of justice, has the right of presiding in it. It is divided into three sections: 1°. Section des Requêtes, which examines whether the petitions or appeals are to be received. 2°. Section de Cassation civile, which decides upon appeals in civil cases. 3°. Section de Cassation criminelle, which decides upon appeals in criminal matters. The sections do not decide upon the main question, but only on the competency of the other courts, and the legality of the forms and principle of law by which the case has been already tried. If the law is found to have been violated, the sentence of the inferior court is annulled, and the case is sent to be tried again by another court. If this second court decides the case in the same manner as the first, and a petition against the decision is again laid before the Court of Cassation, then the three sections unite together in order to examine the case anew, and if they find reason to pass a second reversal, the case is sent to be tried before another court. Should this third court decide in the same manner as the other courts, and a petition against the decision be again presented to the Court of Cassation, the court requests a final explanation of the law on the point at issue from the legislature.

The institution of the Court of Cassation has proved highly beneficial to France; it has acted as a watchful guardian of the laws; it has afforded protection to the citizens against the arbitrary acts, and the misjudgments or misconstructions of the other judicial courts of the country. Placed by the nature of its office out of the immediate influence of political passions, it has maintained its high character for strict impartiality throughout all the changes of government and administration. Many of the most distinguished jurists of France are numbered among its members. We can only mention here the names of Henrion de Pansey, who was long president, and is known for his juridical works; and Merlin de Douai, who was procureur to the court, and is the author of the 'Répertoire de Jurisprudence,' 16 vols. 4to. See an able article on the Cour de Cassation in the 'Encyclopédie de Droit' (vol. vii.), by Monsieur Delangle.

CASSIN. A bitter principle of unknown composition contained in cassia.

CASSIOPEIA. This constellation is called Cassiopeia (κασσιόπεια) by Aratus, and Cassiopea by Manilius. In the Greek fable, Cassiopeia is the wife of Cepheus and mother of Andromeda, placed in the heavens with her head from the pole, so as to turn round apparently upside down, because (according to Hyginus) she boasted of her own beauty as superior to that of the Nereids. This constellation may be found by looking on the side of the pole opposite to the Great Bear, where will be seen five rather bright stars disposed in something like an M. These stars are also in a line drawn from Capella to the bright star in Cygnus, and about half way between them. The old figure is that of a woman sitting in a chair or throne, with a branch in her hand. The constellation is on the meridian at midnight, about the end of Septem-

ber, and at eight P.M. about the end of November. The remarkable star which appeared in this constellation in 1572 has been noticed in TYCHO BRAHÉ, in the BIOGRAPHICAL DIVISION, who also affirms that similar stars appeared in 945 and 1264, whence Sir J. Herschel thinks it possible another such appearance may take place in 1872. But the authority for the first appearance is that of a contemporary of Tycho Brahé, from nameless manuscripts, and as comets are recorded in or about both 945 and 1264, these may have been the stars spoken of. See the 'Companion to the Maps of the Stars, of the Society for the Diffusion of Useful Knowledge.' Baldwin, 1836, p. 86.

The following are the principal stars in this constellation:—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
β	11	7	2.5
κ	15	126	4
ζ	17	153	4
α	18	169	3
η	24	218	4
γ	27	253	3
θ	33	339	4.5
δ	37	416	3
ϵ	45	564	3

CASTANETS, a musical instrument of percussion, of Moorish origin, composed of two small concave pieces of chestnut wood (hence the name) or of ivory, in the form of cockle-shells, united at one end by a string, hung on the forefinger and thumb, and struck together in musical time, while the performer is dancing.

CASTES. [HINDOOS, CASTES OF].

CASTIN. A substance hitherto imperfectly examined, contained in the fruit of the *vitex Agnus castus*.

CASTING. It is desirable to point out under what headings the reader will find descriptions of those processes which are known by the common name of *Casting*. This operation is generally understood to mean, the pouring of a metal or some other substance, while in a fluid or semi-fluid state, into a mould. The fluidity may be caused by heat or by some other agent, but the cast, or moulded article, always solidifies in the mould. The manufacture of great iron castings is described under FOUNDRY; that of bells under BELL; that of metal statues under BRONZE; that of plaster statues under SCULPTURE; that of artillery under CANNON; that of ornamental earthenware, or china-ware (where the material is poured in a liquid state into a mould, instead of being pressed in a dough-like state on a mould), under POTTERY and PORCELAIN. Various other applications are incidentally noticed under BUTTON, COPPER, LEAD, STEEL, &c. We will simply notice in this place a remarkable patented invention in casting, not because it applies to any one department of industry, but because it seems to have a useful applicability to many kinds. It was patented a few years ago by Mr. Fairbairn, and relates not so much to the casting in moulds, as to the making of the moulds themselves. The article or model of which a mould is to be made is to be cut in half in the direction of its widest plane. The two parts are then attached to opposite sides of a plate or diaphragm. Two half-moulds are successively made from these two parts, and are fitted accurately together when regular castings are to be taken from the mould. It is considered that time and labour may be economised by this means, by attaching two or more articles to the opposite sides of the diaphragm, and then forming suitable channels for the flow of the molten metal. For *under-cut* articles, those parts require to be loosely attached, so as to be raised with the sand-mould.

CASTLE, from the Latin *castellum*, a diminutive of *castrum*, an encampment, is a walled inclosure with a tower or towers, strongly constructed and intended as a place of safety. Numerous castles, for the most part in ruins, still remain in various parts of Great Britain, France, Germany, Italy, and in the East; but our remarks will be principally confined to those of this country. The castles of England consist almost entirely of those erected after the Norman Conquest; but there are a few fragments of Roman date, and some portions erected prior to the Norman invasion.

In various parts of England, Scotland, Ireland, and Wales, there are numerous encampments or castles, mostly occupying the summits of hills, which have been ascribed to the aboriginal inhabitants. Among the most remarkable are the Herefordshire Beacon, on the Malvern Hills, in Worcestershire; the Caer-Caradock, near Church Stretton, in Shropshire; Moel Arthur, in Flintshire; Chun Castle, in Cornwall; and Maiden Castle, in Dorsetshire. (Britton's 'Arch. Dict.')

Roman Castra were probably sometimes formed on the sites of British works. Richborough Castle, in Kent, perhaps the earliest Roman castle constructed in this island, has been conjectured to have been formed in the reign of Claudius, and completed by Severus (Batteley's 'Antiq. Rutupinae,' pp. 6, 14, &c.), but this is mere conjecture. The leading features of a stationary castle or encampment built by the Romans still remain. The basement of the Sacellum, or small temple for depositing the ensigns, forms an important feature in this castle; and in the walls some antiquaries believe they can find traces of the four gates. King ('Munimenta Antiqua,' vol. ii. p. 10) gives a plan and full particulars, made out when the ruins were in a

much more perfect state than they now are. According to this plan, the entrance through the north-east wall is by one of the two gates (c)

[Plan of Richborough Castle.]

called by the Romans the Porta Principalis, and which became in after-times the postern gate. The Prætorian gate he supposes to have been on the side of the slope towards the estuary, which formerly bounded this side of the castle. The second principal gate was opposite the first principal gate or postern; and the Decuman gate and the Prætorian are presumed to have been nearly opposite. The form of this castle, like Burgh, is nearly a rectangular parallelogram, with rows of bricks placed at intervals in the walls in a horizontal position. These layers of bricks formed a fresh foundation for every succeeding layer.

Saxon castle-building was probably borrowed from the Romanised Britons, who had acquired a taste and knowledge of the arts from the Romans. Thus, in Pevensey, there are works that have an appearance of Roman character and design, and yet are so much ruder in execution than any other Roman works, that they can only be referred to a time when the knowledge of the Roman arts, though yet fresh in the memory of the inhabitants, might probably be on the decline. But the remains of castles which can with any approach to certainty be termed Saxon are few and of little consequence. King, the great authority with the past generation of antiquaries, wrote a work (the 'Munimenta Antiqua') full of learning and ingenuity, but sadly wanting in judgment, and abounding in fanciful conclusions and false inferences, in which he lays down very decidedly the distinctions between Norman and pre-Norman castles, and gives plans and descriptions of many of Saxon as well as of Norman date. Among many others, King considers Peak Castle, Castleton, Derbyshire, to be a genuine Saxon castle, from the style of its architecture and the appearance of herring-bone masonry in the walls; but what he regards as Saxon work probably belonged to an earlier building, and there is little reason to suppose that the castle, as it at present appears, is of an earlier date than the first half of the 12th century. We give his plan as an example of one of these so-called Saxon castles.

[Plan of Peak Castle, Castleton, Derbyshire.]

The keep (a) is attached to the walls of the castle, which is also fortified with one small square tower and another half tower. The

attachment of the keep-tower to the walls of the castle is regarded by writers of this school as a characteristic of the Saxon castle. The length is about 200 feet by a varying width extending to about 150 feet.

King also gives some plans and views of English castles which he thinks may have been constructed after the plan of Syrian castles, to which he argues they bear, in many parts of their plan, a strong resemblance. Launceston, Brunless, and others are mentioned by him as being of Phœnician origin, a position which it is much easier to assert than to prove. Conisborough, another singular castle, is considered by the same author to be an early British work: it is beyond doubt Norman.

There were no doubt fortresses of some strength existing in England when under the Saxon rule, but the little resistance they opposed to the progress of the Conqueror is a proof that they were neither numerous nor of much importance; and it is certain that nearly all the castles now remaining, whether entire or in ruins, date from a period subsequent to that of the Norman invasion. It would seem indeed, according to Asser's statement, that Alfred built castles of wood and stone, and Henry of Huntingdon states that Elfrida, his daughter, built eight castles in three years. William of Malmesbury describes a stone castle built by Athelstan at Exeter in 944. William the Conqueror was a great builder of castles. The 'Reports' of the Records Commissioners mention thirty castles known to have been built during his reign; and he gave the custody of his crown castles to the most powerful and trusty of his Norman followers, as constables or castellans. Forty-nine castles are mentioned in Domesday Book, which notices Arundel as the only one named in the time of the Conqueror. The sons of the Conqueror largely increased the number of castles; and according to Ralph de Diceto in the nineteen years of Stephen's reign 1115 castles were erected. But these were strictly feudal castles, the property and under the virtually uncontrolled authority of the territorial nobility. The 'Saxon Chronicle' speaking of this castle-building time, uses very emphatic language,—“Every rich man built his castles and defended them, and they filled the land full of castles. And they greatly oppressed the wretched people by making them work at these castles; and when the castles were finished, they filled them with devils and evil men.” The practice, however, soon became as inconvenient to the sovereign as to the common people. Henry II. made it unlawful to erect a castle or to fortify (battellare et kinnellare) a residence: and Henry, at least, seldom granted such a licence. It is almost unnecessary to remark that the building of such strong edifices, which in the then state of warfare were often impregnable, is a proof of the insecurity to life and property which prevailed. Every feudal chieftain had his stronghold, round which his immediate retainers rallied for the purpose of mutual defence, or to annoy and plunder their neighbours. A very considerable number of old towns of Europe gradually rose around these baronial fortifications, and it is interesting to trace, in the history of many of these communities, the progress by which the town, originally a miserable dependence on the castle, gradually obtained privileges, and charters, and wealth; and increased in strength and importance exactly in proportion as the owner of the fortress lost both; till finally the castle, from being neglected and deserted, was either levelled with the ground and furnished materials for house-building, or remained in ruins, an enduring monument of the slow but certain victory of the once subject townsmen over their lords.

The Norman castle in its earliest and simplest form consisted in its main features of a keep or stronghold, a base-court, the outer walls or curtain, a gate-house, and a fosse or ditch—except where the natural strength of the position rendered that defence unnecessary.

The keep was the grand feature, the centre and basis of the castle; and it appears to have been derived directly from the strong tower of the Roman walled castle, or permanent station, as that corresponded to the pretorium of the usual encampment. [CAMP, ROMAN.] Usually the Norman keep was square or oblong, built of the ordinary rubble-stone of the neighbourhood, and faced, or only dressed and groined, with ashlar, and having the usual flat pilaster-like Norman buttress. [BUTTRESS.] The walls at the base varied, according to the size of the tower and the importance of the station, from 12 to upwards of 20 feet in thickness; and diminishing to 8 or 10 feet at the summit, which was crowned by a battlement of more than a foot in thickness. Their strength consequently, if measured against the military implements then in use was enormous. Nor were the few polygonal keeps of the early Norman period less strong than the square ones. Indeed, an eminent civil engineer says of that of Conisborough castle (about six miles from Doncaster, supposed to have been erected by William de Warren about 1070), that “Vauban himself could not have contrived a tower capable of greater resistance.” (Cresy, 'Encyc. of Civil Engineering.') In the walls, staircases and chambers, with connecting galleries, were hollowed out at different heights, but they were usually of small size, and only lighted by loops in the lower stories; the upper rooms had the ordinary Norman window. The entrance was generally on the first floor, and reached by an open, narrow, and easily defended staircase; or the staircase was enclosed in a small turret. As examples of these square towers we may refer to those of Newcastles, Rochester, Guildford, &c. Sometimes as at Conisborough, Richmond, Castleton, &c., the keep formed a part of the outer walls, but it was usually placed entirely within the walls, in the strongest and most defensible position, it being intended as the last resort in case of the outworks

being stormed or taken. Sometimes the keep was built on an artificial mound, but sometimes there was a mound, with or without a donjon, in addition to the keep.

The base-court contained the lodgings of the garrison, the store-houses, and various offices. The surrounding walls were from 20 to 25 feet high; occasionally strengthened with towers or bastions; and had a terrace walk with a parapet. The gatehouse was of great strength, flanked with towers, and sometimes perhaps, though not often, in the earlier castles, defended by a barbican. [BARBICAN.] From the gatehouse, a drawbridge was let down across the fosse, which was sometimes a dry, sometimes a wet ditch.

Rochester castle, which stands on a small eminence near the bridge over the Medway, is a fine example of a Norman castle of this period. It was probably rebuilt by the Normans, soon after the conquest, on the site of a more ancient castle.

[Rochester Castle and Keep.]

The keep, "which originally consisted of four floors, including the basement or dungeon story, is about 70 feet square at the base, with walls varying from 13 to 8 feet in thickness, and rising to the height of 105 feet to the top of one of the angular turrets. The walls of the ground-floor slope or bend inwards; but from that to the top they are continued perpendicularly. Externally there is a pilaster buttress near the centre of each side, and at three angles are square staircase turrets, and a rounded turret at the fourth angle. At the north face is a projecting work, forming a sort of vestibule to the chief entrance door-way to the first floor, and this is approached by a flight of steps commencing at the western side, and returning round the corner. The walls, doors, and windows are constructed to repel assailants.

"The first ascent was by a flight of twelve or thirteen steps, leading round the north-west angle to an arched door-way, beneath which a flight of seven steps led forward to a draw-bridge that connected with the arched gateway to the entrance-tower: this opened into the vestibule, between which and the keep there were no other avenues of communication than by a third arched passage in the thickness of the wall. This latter inlet to the body of the keep was defended by a massive door and portcullis, the hinges and grooves of which remain; and in the roof are openings for the purpose of showering missiles on the heads of assailants."

The interior of the keep is divided longitudinally by a strong wall into nearly equal parts, which communicate by open arches on each floor. In the centre of this wall is a well of considerable depth, 2 feet 9 inches in diameter, neatly wrought, open to the very top of the keep, and communicating with every story. There were three stone floors besides the basement. "The basement story was low and gloomy; here the munition and stores for the use of the garrison were deposited. In the north-east angle is a circular winding staircase, communicating from the ground to the summit, and within the south wall is a square passage, or funnel, which also communicates with the upper floors, and from its singularity has given rise to much fanciful speculation; among other conjectures, it has been considered to have been used for the conveyance of stores to the upper part of the keep." On the north side is a flight of steps leading to what is known as the dungeon.

"The first floor, which seems to have been that occupied by the soldiery, and into which was an entrance from without, was 22 feet in height. Besides seven large loop-holes, larger than those beneath,

there were two spacious conical fire-places, the flues of which gradually contracted to the outer part of the walls, where there were small apertures for the smoke. Another, but smaller fireplace is contained in a little apartment within the north-west angle, and here also were two very curiously-contrived and well-defended windows, designed to command a view of what was passing on the steps of entrance. Within the east floor of this wall is a gallery, together with some private apartments, the openings into which were well calculated to secure those who might be there stationed to watch a besieging army. In the south-east angle is a second circular staircase, which, as well as that in the opposite tower, opens to the top of the building.

"The second floor consisted of the state apartments, 28 feet in height, and was more ornamented and lofty than either of the others. These communicated by four large semicircular arches, formed in the partition wall, which was sustained by massive columns and half columns. Within the thickness of the wall round the upper part of this floor is a gallery which traverses the whole keep, and receives light from without through twenty-five small windows: the exteriors of these were more highly finished than any of the lower openings, and inwardly they appear to have been secured by wooden shutters, the hinges and bare holes of which still remain. This gallery was also open to the state-apartments by six arches on each side." (Britton's 'Architectural Antiquities,' vol. iii.) The upper floor was about 16 feet high, and has likewise a gallery, with openings both within and without, similar to the preceding. From the remains of a large arch in the south-east corner it seems probable that the chapel was placed here.

The roof of the keep, as well as the floors, have been destroyed: the former, probably, consisted of a platform on a level with the top of the wall within the parapet: the latter was about 5 feet high, and had embrasures about 2 feet wide. The four towers at the angles were raised another story, and had also small platforms with parapets and embrasures. The gutters which conveyed the water from the platform still remain.

The outward walls, which formed an irregular parallelogram of about 300 feet in length, were strengthened by several square and round towers embrasured and provided with loopholes and machicolations. On the north-east was the principal entrance, which was defended by a tower gateway with outworks at the sides.

The later Norman castles, of which those of the time of Edward I. may be regarded as the most perfect examples, covered a much more extensive area, were much more complex and elaborate in plan and more ornamental in design, and presented many of them a magnificent appearance. Such were, among others, those of Windsor, Conway, Caernarvon, Cardiff, Chepstow, Kenilworth, Warwick, Hedingham, Porchester, and many more. The keep was of stately proportions, sometimes assuming the character of an open quadrangle or inner baillie, defended by gate-houses and flanked by towers. The base-court was divided into two parts, sometimes into three,—the outer baillie, in which were the stables, and sometimes a mound, or small cavalier; the middle baillie, containing the servants' apartments and domestic offices; and the inner baillie (which formed the keep), around which were concentric lines of defence, and in which were the hall and the chapel, often a very handsome building. The outer walls had embrasures, and were strengthened by turrets, sometimes of the kind called bastions, and towers, occasionally of large size, and either round, square, or multangular, as the Beauchamp Tower, Warwick Castle. The gate-houses were distinct works, with large drum or circular towers, as at Chepstow, Beaumaris, &c.; the entrances were machicolated, had portcullises, were nearly always approached by drawbridges, and often defended by barbicans. There were also posterns or small doorways in the walls, with or without drawbridges. That these castles were fully adequate to their purpose is shown by their prolonged resistance to considerable forces; and when taken, it was frequently only after repeated attacks,—first the barbican, then the outer baillie, then the inner baillie, and at last the great tower, having fallen.

We give a plan of Porchester Castle, Hampshire, which may serve as an illustration of the way in which some of the larger castles only reached their ultimate magnitude in the course of a long series of years. Porchester Castle is supposed to occupy the site of a Roman station. Stow, indeed ('Annals,' p. 12), supposes the founder to have been a Briton, one Gurgunstus. It is rectangular, with hollow circular towers (a) at the angles and sides. The sites of the Roman gates (b, c), most probably the Decuman and Prætorian, have been fitted up with gates constructed after the Norman style of fortifying castellated entrances. The area of Porchester is 620 feet by 610. At the north-west angle a square Norman (or, as King insists, 'Munimenta Ant.,' ii. 28, a Saxon) keep (e), 57 feet by 58, has usurped the place of one of the circular Roman towers. To this tower an addition was subsequently made, and at the same time an inner baillie or ballium was constructed within the outer baillie formed by the large Roman inclosure. This keep was the citadel of the castle, and was the residence of the chief officer. The church in this instance stands at some distance from the keep, it having, as is supposed, been made to occupy the site of the Roman sacellum. Close to the Prætorian gate it is still in good preservation. At Caistor, in Norfolk, the church also occupies the site of what was probably the ancient temple. The keep at Porchester stands upon the outward wall of the castle area

itself. The *Themelii* (Θεμέλιοι, layers of bricks) are seen in parts of the Roman walls, which, like all the walls of Roman castra, are of rubble; while the Norman works are usually faced with squared stones. Pevensey Castle, in Sussex, is also considered to be in part a late

[Plan of Porchester Castle, Hants.]

Roman work, if not an Anglo-Roman building. The *Themelii* are not laid horizontally, as at Richborough and Burgh, but more like the Saxon herring-bone. Like Porchester, it has had many subsequent additions in later times. The earlier works are far more durable than the later constructions. The plan is an irregular curve with solid towers, and a curved inner baillium with hollow towers, and a keep. The plan given in King's 'Munimenta' is very incorrect, having nearly the form of a circle, while the real shape approaches to that of a triangle with the ends round. The walls at Pevensey average 10 feet in thickness and 20 feet in height.

The Norman castle formed before the invention of gunpowder an almost impregnable stronghold; but it was at best a gloomy and uncomfortable abode. When the triumphs of Edward III. secured internal as well as external peace and security, and the arts of peace began to be cultivated, the want was felt of dwellings of a more domestic character, and better fitted for the growing splendour of private life. To the castles, halls and apartments of a more luxurious character were added, and various alterations were made. But another class of abode began to be erected, midway in character between the stern feudal castle of the past and the stately mansion of a future generation. These were the Castellated Mansions, in which, while comfort and even elegance were sought after, security was not neglected. Something of the appearance as well as the name of a castle was retained, but little of its dreariness. It was thought sufficient if, by means of its moat and drawbridge, its strong towers and pierced turrets, its treble portcullised doors, and its thick embattled walls, it could withstand the casual attack of a marauding band, though it might not be capable of enduring a regular siege. Of this class and time is Hever Castle, Kent, erected by William de Hever, lord of the manor, who obtained a licence from Edward III. to erect his manor-house at Hever "more castelli." The building is a quadrangle inclosing a court-yard, and is surrounded by a moat. The principal front consists of the great entrance gateway, which is a large and lofty stone structure, flanked by two square towers. Answering in some measure to the Norman keep, this part was made of great strength. The approach was by a drawbridge (now replaced by a fixed wooden bridge). Over the gateway impend bold machicolations. The towers are not only embattled, but pierced with oilets and loopholes. Within the gateway are three strong doors, one behind each other, and each defended by a portcullis; and in the gate-house were guard-rooms, fitted with all necessary appliances.

The progress may easily be traced from buildings of this kind to the purely domestic palatial mansions of recent years, through the beautiful "halls" and "castles" still embattled and built with considerable show of strength, and, indeed, as was proved by some of them in the civil-war of the reign of Charles I., capable of resisting a considerable force for some time, but really constructed as private dwelling-houses. As examples of this kind may be cited, Aydon Castle, Northumberland; Penshurst, Kent; Ludlow Castle, Shropshire; Oxburgh Hall, Norfolk; and many others, till as we descend,

every feature of a defensive kind disappears. To trace this progress, however, does not fall within the province of the present article. The last stage of the "castle" proper, is perhaps marked by brick buildings like Herstmonceux Castle, near Pevensey, Sussex, which is of brick, and perhaps the oldest existing edifice constructed of brick after the re-introduction of that material. It was built in 1440 by Sir Roger de Fiennes, treasurer to Henry VI., pursuant to a licence obtained from that monarch "to embattle and fortify his manor-house at Herstmonceux." The castle is much on the plan of that at Hever. It is square in plan, the sides being 214 feet, the front 206, and it is surrounded with a moat. The front consists of a grand central gate-house, with machicolated towers on each side of the gateway, over which are machicolations, and within were portcullises. At the angles, and also at the sides, are lofty embattled towers. Another of these brick castles is Tattershall, in Lincolnshire, erected about 1455, which consists of a large square brick tower, with polygonal turrets at the angles. Others occur at Thornbury, Caistor, and elsewhere. Thornbury, begun in 1540, and Longford erected in 1591, were the last mansions erected in England with any pretence to a military character prior to the imitative castles of the last and present centuries.

Mr. G. T. Clark, in a very able paper on Castles, in vol. i. of the 'Archæological Journal,' states the number of castles which are known to exist, either perfect or in ruins, in the United Kingdom, to be, in England, 461; Wales, 107; Scotland, 155; Ireland, 120; in all 843; but it is very difficult to obtain a complete list, and he is no doubt within the mark in saying that the true number is probably near 1000.

Few parts of Europe contain so many ruins of castles as the banks of the Rhine. They are almost all built on an irregular plan, and adapted to the nature of the rugged sites on which they are placed. The most remarkable both for their size and history are the castles of Ehrenbreitstein and Heidelberg.

There are very many ruins of fine castles in Normandy and in the Pays des Vosges. Switzerland has also its castles, but they are on a smaller scale. The French castles were occasionally bastilles, like Villebon, the castle of the Duc de Sully.

For further information on castles the reader is referred to Britton's 'Archæological Antiquities,' Dallaway's account of castles in his 'Discourse on Architecture in England;' 'Ancient Castles of England and Wales,' engraved by W. Woolnoth, with descriptions by E. W. Brayley, jun.; Mr. Clarke's paper on Castles in the 'Archæological Journal,' already referred to; the article Castle in the 'Dictionary of the Architectural Publication Society;' Billing's 'Baronial Antiquities of Scotland;' and (making allowance for the erroneous theory upon which it goes, and consequently distrusting the so-called "restorations") King's 'Munimenta Antiqua;' also the drawings and prints of castles in the king's library of the British Museum; and notices of castles in the 'Archæologia,' the 'Gentleman's Magazine,' and the 'Archæological Journal,' and 'Journal of the Archæological Association.' On the Castles of France, and the student must remember they are the prototypes of the castles of England, a most careful account will be found in the 'Dictionnaire' of M. Viollet le Duc, article Chateau; and very full and valuable accounts in M. de Caumont's 'Cours d'Antiquités,' vol. v., and 'Architecture Civile et Militaire,' p. 261 to the end.

CASTOR, or α Geminorum, one of the bright stars in the head of the twins from which the constellation gets its name, being the nearer of the two to the pole. [GEMINI.] This is a remarkable double star; that is to say, consists of two stars so close together as to be inseparable to the naked eye, which are nearly equal, and compose the appearance of the third magnitude. The two are, however, easily separated by a moderately good telescope. Sir J. Herschel has determined the elements of the orbit in which each star moves round the other. ('Mem. R. Astron. Soc.,' v. p. 196.) He calls the star "the largest and finest of all the double stars in our hemisphere, and that whose unequivocal angular motion first impressed on my father's mind a full conviction of the reality of his long-cherished views on the subject of the binary stars." By observations of Bradley and Pound, Maskelyne, W. Herschel, Professor Struve, his own, and Sir J. South, he has deduced the following elements of the elliptic orbit of each star round the other; major semiaxis, 8.086"; eccentricity, .7582; inclination of the real orbit to the apparent orbit on the sphere of the heavens, 70° 3'; position of node, 58° 6'; perihelion measured from node on orbit, 97° 29'; period of revolution, 253 years; the last period of closest approach was 1855.

CASTOR FIBER (Linn.), the Beaver. Into a cavity situated at the posterior part of the trunk, both in the male and female animal, the urinary organs and anus open, and in this are also lodged two pear-shaped bags, which receive the secretion of certain glands, which is termed castor. The bags are united by a ligament supposed to be their excretory duct. The secretion is at first in a liquid state about the consistence of syrup, but it ultimately becomes solid, losing some of its odour and activity. As met with in commerce it is of two kinds, the Russian and American. The American is of two sorts, both imported by the Hudson's Bay Company, yet one is called the Hudson's Bay castoreum, the other is called Canadian; the first is the best. The Russian is the rarest and most esteemed; it is more carefully managed from the time of its excision, being first dried in smoke, and often wrapped in swine's bladder. The bags of Russian castor are in pairs of unequal size, from 3 to 4 inches long, and 1½ to 2 inches

broad towards the base; the skin thick, smooth, of a brownish red or yellow, the mass more or less friable or tenacious according to age; adhering to them are in general the remains of the oil or fat bags. The odour is peculiar, very penetrating, and unpleasant; the taste is also peculiar, bitterish, somewhat acrid or aromatic, and enduring. The bags of American castor are smaller, narrower at the base, of a great variety of colours, yellow or orange-brown or brownish-black, the skin thinner, more of the consistence of paper, the surface often wrinkled, and in general no vestiges of the oil-bags present. Both kinds are occasionally slit open and a part of their contents abstracted. A seam on the surface and an internal cavity, sometimes filled with other materials, indicate when this fraud has been effected.

Castor should be kept in a cool place, in a well-corked bottle.

Brandes, from 1000 parts of Canadian castor, obtained:—

Volatile oil	10.0
Castorine pure	7.0
Castorine with carbonate, urate, and benzoate of lime	3.5
Castoreum-resinoid	120.0
Castoreum-resinoid with benzoate and urate of lime	16.0
Castoreum-resinoid obtained by ether	1.0
Castoreum-resinoid from watery extract	1.5
Albumen with trace of phosphate of lime	0.5
Osmazome-like matter	2.0
Phosphate of lime	14.0
Carbonate of lime	336.0
Carbonate of magnesia	4.0
Sulphate of potassa, sulphate and phosphate of lime	2.0
Animal mucus	23.0
Carbonate of ammonia	8.2
Animal matter	23.0
Skin and salts	192.0
Loss and moisture	229.1

Occasionally *carbolic acid* and *salicine* are found in Canadian castoreum. The latter is derived from the willows on which the beaver feeds. Russian castoreum has far more volatile oil and resin.

Castorine is also called *Castoreum camphor*. It may be obtained by boiling one part of castor in six of alcohol, and leaving the filtered liquid to cool, when it falls to the bottom. It is very combustible, and is neither acid nor alkaline; it has a copperish taste. It crystallises in long diaphanous fasciculated prisms, is insoluble in cold water and cold alcohol, but dissolves in 100 parts of boiling alcohol, also in the volatile oils. Bizio considers it the active principle of castor, but it is more probable that the active properties depend upon the essential oil and resinoid principle: the most proper menstruum to take up these is alcohol or the ethers. Rectified spirit is preferable to proof spirit to form the tincture. The compound tincture of the Edinburgh Pharmacopœia is a valuable form of exhibition. It should never be prepared as an extract or a decoction. The powder is not an objectionable form, if too high a temperature be not employed to dry and render it friable.

If from five to ten grains of castor be received into the stomach, a gentle heat is felt in that organ; a more considerable dose causes a still greater sense of heat, and increased strength and frequency of pulse. That the principles of castor pass into the blood is proved by the secretions acquiring its odour during the employment of it internally. It appears to act specially on the cerebro-spinal and ganglionic systems of nerves, so as to modify their condition. Hence it is used against spasmodic symptoms, and to restore the healthy action of the nervous system when that is disturbed. It is rarely given to excite the digestive organs, the heart, or the lungs, but chiefly to influence the brain, the spinal cord, and the uterus. Its employment is sometimes followed by very profound sleep, which, if the dose be moderate, need not excite alarm. Castor is most useful in hysteria, hypochondriasis, nervous palpitations of the heart, convulsive hiccup, colic, and similar diseases. It ought not to be employed if any morbid sensibility of the stomach or enlargement of the heart exist.

CASTOR OIL. [CROTON.]

CASTORIC ACID. [CASTORIN.]

CASTORIN. A white, crystalline, fatty substance contained in the secretion of the beaver, known in pharmacy as *castoreum*. By long boiling with nitric acid it is converted into *castoric acid*. Neither of these substances has been analysed. Castorin appears to be allied to *cholesterin*.

CASUISTRY, the name of a science which professes to give rules for the resolution of doubts of conscience. It was greatly cultivated in the 15th and 16th centuries, especially by the Jesuits, and was calculated to be a very efficient instrument of the crafty policy ascribed to that order. For the confessor, who professed himself able to lay down exact rules of conduct, to weigh the merits of two conflicting duties, and decide which was the greater of two sins, had the means of obtaining an almost boundless influence over his penitent. But casuistry under some form, and more or less elaborated, must be studied wherever confession, penitence, and absolution under the guidance of the priesthood are doctrines of a church, and where con-

sequently the younger, more inexperienced, or less learned priests, require authoritative direction in difficult cases. The science of casuistry, however, though so liable to abuse that it has been termed, not inaptly, the "art of quibbling with God," has been cultivated in the reformed as well as the papal church, and for a specimen of its subtleties we may refer to Bishop Taylor's 'Ductor Dubitantium, or Rule of Conscience.' There is a professor of casuistry in the university of Cambridge, whose lectures, however, have been discontinued. For a full account of the casuists, see Mayer's 'Bibliotheca of Casuists,' divided into three heads: Lutheran, Calvinist, and Roman. Casuistical works, or manuals for the guidance of priests, are constantly on sale in Roman Catholic countries.

CATACOMBS, subterranean excavations, used as vaults for the burial of the dead. They are found in most parts of the world, but chiefly in those countries which, like Italy, Sicily, and Egypt, offer extensive beds of soft *tufo* or of some other stone which is easily cut, and which yet is adhesive enough not to fall in. The probable origin of many of them is that they were mere quarries, where materials were dug for building; and when spacious caverns were thus made, the adaptation of them as places of interment was natural and obvious.

The catacombs of Rome, the entrance into which is on the Via Appia, at a short distance from the city, are very extensive, and have evidently been used both as burying places and as places of worship; for Christian altars, inscriptions, and paintings, of a very early date, and of great interest in the history of early Christian art and iconography, still exist in these gloomy crypts. The commonly received opinion is, that during the persecutions the early Christians retired thither to worship in secret, and that the remains of many thousands of martyrs were deposited there apart from the pagan Romans. The long galleries of these catacombs, which twist and turn in a curious manner, are, generally speaking, about eight feet high and five feet wide; there are mostly three tiers of graves or cells, running lengthwise, one above another, along the galleries, and in some instances there are two and even three of these dark galleries, beneath one another. At certain irregular intervals these subterranean passages converge, and then expand into large vaulted chambers, which still look like churches. The more regular chapels met with in many of them are the works of a later age, some of them having been formed by order of the popes, and executed with great care. Although the cross and the monogram of Christ have long been affixed to every accessible corner, and the traditions of the Romish church give the exclusive occupancy of the catacombs to the Christian dead, there seems good ground to believe that the ancient and pagan Romans deposited their dead in them. According to the ciceroni, or guides, taking in their different ramifications, these cold gloomy galleries run for twenty miles under ground, and several recent travellers have stated their length at six miles, confessing, however, that from their having fallen in and become dangerous in many parts it is not possible to penetrate them to anything like that extent. Agincourt, 'History of Art by its Monuments,' has, in Vol. I. plates ix.-xiii., collected together plans, sections, views, and illustrations of the contents of "The most celebrated Catacombs, Pagan and Christian."

The catacombs of Naples, which are cut in *tufo* under the hill called Capo di Monte, do not differ materially from those of Rome, except that the main streets are much wider; and their real extent, which is considerable, is liable to the same exaggeration. The entrance into them is rendered horrible by a vast heap of skulls and bones, the remains of the victims of a plague which desolated Naples in the 16th century. Some of these passages are almost covered with Christian symbols, and the paintings in one of the large vaulted chambers or churches, though badly drawn, have retained a wonderful freshness of colouring, considering their underground damp situation. The spreading palm-tree is a frequent feature in these pictures. On the site of the ancient Etruscan city, Tarquinia, about three miles from the small modern town of Corneto, catacombs of immense extent have been opened within the last century and a half. They were excavated in the white calcareous stone of which the hill is formed on which the ancient city stood, and they must have been in use at the best time of Etruscan art, as the walls are decorated with fresco paintings of figures; friezes executed with great skill and spirit, and vases of admirable form and decoration, mosaics, arms, &c., have been found in them. (D'Agincourt; Inghirami, 'Monumenti Etruschi'; and Von Stackelberg, 'Aelteste Denkmäler der Malerei, oder Wandgemälde aus den Hypogäen von Tarquinii.') At Palermo and at Syracuse there are similar recesses; the catacombs of the latter place being very considerable, and laid out with great regularity, while close in the neighbourhood there are plenty of quarries and subterranean excavations that might have been turned to the same uses. These catacombs form extensive streets of tombs with circular halls, far more regular in plan than the catacombs of Rome; and in their case it is evident that they were originally used by the pagan population, and subsequently by the Christians, as they are filled with Greek and Roman as well as Christian and Saracenic tombs. The entrance to these catacombs is under the small church of San Giovanni, in the lower part of Acradina. In the island of Malta, catacombs of a much more limited extent are found at Città Vecchia, cut into the rock on which that old town stands. They occur again in the Greek islands of the Archipelago. At Milo (one of the Cyclades) we have seen a mountain completely honeycombed with

them, a labyrinth of tombs running through it in all directions. From the *bassi-rilievi*, figures in terra cotta, and other works of art found in them, it was evident that these tombs were of a date far anterior to the Christian epoch.

In Egypt these subterranean excavations occur in all parts of the country where there is rock, but they have neither the extent nor the form of those of Rome or Naples. Those of Abousir are no doubt very extensive, but they have not yet been fully explored. There are extensive excavations near Alexandria, which appear from the style of the ornamental parts to belong to the Greek period. The anxiety of the Egyptians to preserve from decay the bodies of their friends and the bodies of sacred animals, may sufficiently account for the number of these excavations, and for their being so well tenanted. For an account of these excavations the reader may consult Belzoni, Salt, Pococke, Legh, Henniker, or any respectable modern traveller in Egypt, and the works of Sir G. Wilkinson. In Peru, and in some other parts of South America, both mummies and catacombs have been discovered. The mummies however are frequently buried in the sand, and the size of the catacombs can bear no comparison with the extent of those of Italy and Egypt.

The catacombs at Paris could not be called catacombs with any propriety until recent times, when, by a decree of the French government, all the churchyards within the city which had been crammed to a loathsome and dangerous degree, were emptied of their contents, and the skulls and bones sent to the spacious subterranean quarries, where they are now arranged in a manner that is grotesquely horrible.

CATALEPSY, or TRANCE (from the Greek *κατάληψις*, *catalepsis*, literally, "a seizing"), to which is closely allied *extasy*, or the *extatic trance*, is a disease of the nervous system, attended with an abolition of sensation, and of intellectual operation, and with a peculiar condition of the muscles of voluntary motion, those muscles retaining during the paroxysm precisely the same position they were in at the moment of the attack, while the action of the heart and the respiratory functions are but little affected. The malady consists of a great disturbance or an absolute suspension of the functions of the animal life, while the processes of the organic life go on with comparatively little change.

A lively description of a person labouring under a paroxysm of this disease has been given by Dr. Jebb: "My patient," says this physician, who is describing the condition of a young lady who was the subject of this curious malady, "was seized with an attack just as I was announced. At that moment she was employed in netting; she was in the act of passing the needle through the mesh; in that position she became immovably rigid, exhibiting, in a pleasing form, a figure of deathlike sleep, beyond the power of art to imitate, or the imagination to conceive. Her forehead was serene, her features perfectly composed. The paleness of her colour, and her breathing, which at a distance was scarcely perceptible, operated in rendering the similitude to marble more exact and striking. The position of her fingers, hands, and arms was altered with difficulty, but preserved every form of flexure they acquired: nor were the muscles of the neck exempted from this law, her head maintaining every situation in which the hand could place it, as firmly as her limbs."

This disease is so rare, while it is not unfrequently feigned, that a suspicion has been excited as to the reality of its existence. Without doubt it is often assumed, and that under circumstances which afford no assignable motive for the deception; but still cases are on record, of which that which has just been recited may be taken as an example, which leave no room to doubt that the affection is not invariably simulated, but is sometimes, though not often, a real disease. The disease, when undoubtedly real, is attended with a disturbed state of almost all the functions of the body. There is commonly severe headache, often giddiness, noise in the ears, lassitude, languor, yawning, a disturbed condition of the gastric and intestinal organs, and, more especially, in the male, of the biliary, and, in the female, of the uterine organs. The functions of the spinal cord and brain are at the same time disordered. The whole muscular system is preternaturally irritable or mobile; there is present a long train of symptoms, commonly termed nervous; the intellectual operations are dull and confused, and the temper is mutable and irascible.

During the paroxysm, which commonly comes on quite suddenly, the patient retains precisely the same posture of the body as at the moment of the attack; even the expression of the countenance which existed at that instant remains unchanged as long as the paroxysm lasts; the eyes, whether open or shut, are perfectly fixed; any position in which any part of the body under the influence of the voluntary muscles may be placed, as the head, the trunk, or the limbs, is retained without the slightest deviation; this fixedness and unchangeableness in the attitude giving to the subject of the malady a striking resemblance to a statue.

The countenance during the paroxysm is almost always paler than natural, though it is stated that it has occasionally been observed to be slightly flushed. The skin in general is unusually cold, excepting about the head, where the heat is sometimes even greater than natural, indicating a preternatural determination of blood to the brain, as well as to all the textures that surround it. The action of the heart is so greatly depressed, that it is often altogether imperceptible, and when capable of being distinguished, it is either slow, occasionally below

50 in the minute, or quick and small. The respiration is sometimes incapable of being distinguished, and is never natural; while the processes of secretion and excretion are performed so languidly as to give little or no indication of their existence; and so, the animal functions being abolished, and the organic being performed in so languid a manner as to be imperceptible, the person is sometimes supposed to be actually dead.

After a period of very uncertain duration, sometimes comprehending only a few minutes, and at other times many hours, occasionally, as is stated, even days, consciousness returns generally with the same suddenness as the attack commenced, the return to consciousness being accompanied with sighing, and followed by pain or confusion in the head, and a sense of lassitude and fatigue. No memory is retained of anything that may have passed during the paroxysm, the very same train of ideas returning when consciousness is restored as were present at the instant it ceased; and even, according to some narratives, the very same sentences which had been suspended by the seizure being pursued at the moment of recovery.

In the most severe form of the paroxysm, sensation, intellectual operation, and voluntary motion are entirely abolished; but when the attack is less complete, consciousness is retained. Still there is no power of making the slightest movement of any part of the body, nor even of producing so much as an articulate sound; and several striking and even appalling cases of this latter modification of the disease are on record.

The modification of cataleptic disorder which constitutes the affection termed *extasy* is generally induced by mental excitement and sustained contemplation of some particular subject, most generally of a religious nature, and more especially when such subjects have raised the passions and engaged the affections. "The patient suddenly seems mentally struck or carried away from all external objects; either standing or sitting in a most excited and impassioned position, with the eyes fixed and open; and sometimes uttering either the most enthusiastic and fervid expressions, or the most earnest denunciations and warnings, or the most absurd exclamations, with the feeling or belief of their reality; and total abstraction from, or unconsciousness of, all surrounding objects or persons."

Such of the cases as were not feigned which some years ago made so much noise in London under the idea of inspiration with "unknown tongues," belong to this affection; the effects produced by the practisers of animal magnetism upon nervous persons are obviously allied to it; and the faculty of improvisation is rarely possessed but under a state of the system perfectly analogous to it; while few who are endowed with this power are in a state of sound health, or consider their faculty otherwise than as a morbid one.

The hypochondriac, the melancholic, and the hysterical temperaments are by much the most predisposed to this disease, while the paroxysm is commonly excited remotely by some disorder of the biliary and digestive organs, or by a suppression or some irregularity of the catamenia; and directly by some powerful mental emotion.

The treatment of the malady must be different in every different case, according to the particular condition of the system, and the nature of the exciting cause. If some derangement of the physical health be the primary cause of the disease, as is almost always the case, the indications of which will commonly be found, if looked for, in the disturbed functions of the brain, the stomach, the liver, the uterus, &c., such remedies must be applied as are calculated to restore these diseased organs to a sound condition.

CATALOGUE (Astronomy.) This is the name given to a list of stars with the means of determining their positions annexed, whether latitudes and longitudes, or right ascensions and declinations. Such a catalogue is not only a register of the stars in question, but also gives the means of computing the effects of precession, aberration, and nutation, and thus finding the absolute place of the star in the heavens at any given time. Another species of catalogue is a register only, being a list of objects which are looked at, not for the purposes of geography or navigation, but as connected with purely physical investigations, such as double stars, nebulae, &c. The places of the objects are only given to such a degree of nearness as will enable the future observer to lay his telescope upon them. We may place in this list all catalogues of comets; and the whole of this second class requires no further description.

Our own actual knowledge of astronomy, so far as the position of the heavenly bodies is concerned, is contained in the catalogues of stars and the Planetary Tables, the latter of which furnish, not the places of the planets, but the elements by which those places are determined. The names of the principal catalogues will be found in their proper places in the article ASTRONOMY, and there would be no use in repeating them here.

A catalogue, such as is now constructed, shows at one given time the places of a number of stars in right ascension and declination, to which are usually annexed various auxiliary quantities to aid in the reduction of the catalogue to another epoch. These, though useful, are not necessary parts, since they might be supplied by each person for himself, whereas nothing could replace the actual observation made at or near the epoch in question. For the instruments employed in the construction of a catalogue see TRANSIT INSTRUMENT, and CIRCLE. The regular work of an observatory, so far as the stars are concerned,

is the incessant observation of their places, with a view not only to amend preceding results, and to destroy the necessary errors of one observation by the average of many, but also to measure more closely the proper motions of the stars, which have, since accurate catalogues began to be formed, become visible in comparing their results. A catalogue of stars therefore has a value for all succeeding generations in proportion to its goodness; the comparison of two distinct catalogues serves both to determine the precession of the equinoxes and the proper motions of the stars.

The declinations of stars are observed by a method which makes their correctness depend either upon a plumb-line, or more commonly, at the present day, upon a double observation of the star: first, directly; secondly, by means of an image reflected from a surface of mercury. The latitude of the place, and the refractions of the atmosphere, must also be well known. The right ascensions of the stars, relatively to each other, depend upon nothing but the correctness of the instrument employed, and the uniform going of the clock. But the absolute right ascensions of the stars are measured from a fictitious point, the *mean equinox*. The real equinox is the point at which the sun crosses the equator; but as this point moves in the heavens with a motion nearly uniform, but at the same time affected with slight irregularities [EQUINOXES, EQUATION OF], the latter are considered as corrections to be applied when necessary; and catalogues always give the right ascension of the stars as measured from the point at which the equinox would be, if it had its average motion, instead of the real motion. The same fiction is adopted in our measurement of time, which proceeds not according to the real sun, but according to a fictitious body which moves, not in the ecliptic, but in the equator; and not as the real sun moves, but with its average motion. Consequently, the value of the absolute right ascensions of a catalogue depends upon the observer's observations of the sun; these may be wrong, more or less, while his relative right ascensions may be very correct; that is, the differences of his right ascensions may be exact, while all his right ascensions may be wrong by the same quantity, arising from a misplacement of the equinox.

In the mean while, since it is certain that there are stars which are much better known than any others, it is usual to make these, which are called *standard stars*, the sole regulators of the clock, that is, to presume that all the difference of right ascension which appears between the places of these stars as deduced from the catalogue, and that obtained from observation, is the fault of the going of the clock; which, corrected by these observations, is made to determine the right ascensions of stars which are presumed to be not so well known. The tendency of this assumption is, to make the latter species of stars as well known as the former; better they cannot be by such a method. The observations of the sun, by which even the standard stars must be regulated, are best made at the solstices (from which the equinoxes can be deduced), and of course occur only twice a-year. There is in the Nautical Almanac for 1862 a catalogue of standard stars, 147 in number, which are reduced, and their places given for every ten days throughout the year. This last refinement, namely, the selection and constant observation of a few particular stars, is due to Maskelyne (1790 and 1805). The standard catalogue of Maskelyne contained only 36 stars. In the present day, the catalogue used for a similar purpose at the Royal Observatory includes 190 stars.

Looking further back, we find that a preceding epoch begins with Bradley, whose discoveries of aberration and nutation enabled him first to reconcile the discrepancies which his predecessors had detected, but could not account for. Flamsteed (whose catalogue was published in 1725) was the first who habitually observed with the transit instrument to the extent of forming a large catalogue. Hevelius (1690) was the first who determined right ascensions, not however by the transit instrument, but by the old method of measuring distances of stars from each other. Tycho Brahe, the restorer of astronomical measurement, furnished the first catalogue in which any material improvement was made upon that of Ptolemy; for those of Albategnius and Ulug Beg hardly merit such a description. The catalogue of Ptolemy is most probably not formed from observation, but from that of Hipparchus, brought down to the time of the latter by an assumed (but erroneous) value of the precession. Delambre found, by taking the value of the precession, as given by Ptolemy himself, and reducing his catalogue of stars to the time of Hipparchus, that it then presented the state of the heavens more nearly than, as given, it could have done in the time of Ptolemy. ('Astron.' vol. i. ch. xvi.)

CATALOGUES. [BIBLIOGRAPHY.]

CATALYSIS and CATALYTIC FORCE. Certain substances, when brought in contact with other substances, act upon them in such a manner as to induce a chemical activity; compounds are decomposed, or new ones formed, although the substance by which these changes are induced is not at all affected. To this class of phenomena Berzelius and Mitscherlich have given the name of "catalytic actions," and to the force by which they imagined them to be produced, the name "catalysis," or "catalytic force."

Among the examples of the operation of this force may be mentioned the peculiar actions which certain metallic oxides, such as those of manganese, copper, and iron, exert in facilitating the decomposition of chlorate of potash. When heated alone, this salt is decomposed with some difficulty; to effect its complete decomposition, the application

of a high temperature is ultimately required. But if a small quantity of binoxide of manganese, for example, be mixed with the salt, and the mixture heated, the decomposition is effected with the application of a comparatively low temperature; the disengagement of oxygen is regular, but so rapid as frequently to produce incandescence of the mass. In this case the quantity of binoxide appears to be immaterial,—it undergoes no change; the decomposition is effected simply by its presence. As additional examples may be mentioned the following phenomena, which have been ascribed to the operation of this force: The conversion of alcohol into ether and water by means of sulphuric acid, in the process of etherification; many operations of fermentation, such as the conversion of sugar into alcohol and carbonic acid, under the influence of yeast; the conversion of starch into sugar in the operation of mashing wort, or in the germination of seeds, under the influence of *diastase*; and the gradual conversion of amygdaline, the bitter principle of the almond, into hydrocyanic acid, hydride of benzoyle, sugar, and formic acid, when it is dissolved in water and mixed with emulsine.

The peculiar action which platinum exerts in effecting combinations and decompositions, has also been commonly attributed to the catalytic force. When the finely divided form of platinum, known as *platinum black*, obtained by precipitating [chloride of platinum by means of zinc, is moistened with alcohol, and exposed to the air, the alcohol rapidly becomes converted into acetic acid. When the same substance is added to a solution of peroxide of hydrogen (HO_2), the latter is immediately decomposed into water and free oxygen. In like manner an acid solution of peroxide of barium (BaO_2), is decomposed into baryta (BaO), and free oxygen. Finely divided platinum has also a remarkable influence in effecting the combination of bodies. When a small quantity of spongy platinum is introduced into a mixture of hydrogen and oxygen it speedily becomes incandescent, and the gases combine with a loud explosion. Similarly, sulphurous acid and oxygen gases, which under ordinary circumstances do not combine, readily do so when passed over gently-heated platinum black. Ammoniacal gas, mixed with excess of oxygen and passed over platinum, is oxidised into nitric acid and water. The reverse operation, that is, conversion of the oxides of nitrogen into ammonia, may also be performed by the agency of platinum. A mixture of binoxide of nitrogen and hydrogen led over gently-heated platinum, yields ammonia and water. $\text{NO}_2 + 5\text{H} = \text{NH}_3 + 2\text{HO}$.

The assumption of the "catalytic," as a special force is at least doubtful. Phenomena have frequently been attributed to its operation, simply because a better explanation was wanting. The progress of science has shown that many reactions at first attributed to catalysis, may be explained on known principles, and further knowledge may be expected to leave none of the catalytic phenomena without other and more satisfactory explanation. The curious and interesting actions which platinum exerts, and which are cited by Berzelius as being the most striking examples of catalytic actions, may be more easily explained as being caused by the operation of the surface. According to Döbereiner, platinum black absorbs 250 times its volume of oxygen, which must, therefore, be contained within its pores in a state of condensation greater than that of liquid water. Hence, when platinum black is placed in a mixture of hydrogen and oxygen, or of binoxide of nitrogen and hydrogen, or of sulphurous acid and oxygen, these gases being condensed on the surface have their particles sufficiently approximated to give play to their mutual affinities, and combination is the result. The action of sheet platinum may also be similarly explained; the recent observations of Deville have shown, that ordinary hammered sheet platinum is full of minute pores.

A curious reaction, usually held to be catalytic, is observed when oxide of silver is added to peroxide of hydrogen; oxygen is liberated, and metallic silver precipitated. Of this, and many other similar phenomena Schönbein has suggested some very ingenious explanations in a paper "on the Connection of Catalysis with Allotropy" ('Phil. Mag.' vol. xiii., pp. 248, 440), and which will be mentioned under the head OZONE. The key to their elucidation will probably ultimately be found in the views first propounded by Brodie in a paper 'On the condition of elements at the moment of chemical change,' read before the Royal Society. ('Phil. Trans.' part ii. 759.)

CATAMARAN is a name given, both in the East and West Indies, to some kinds of rafts which are used in short navigations along the sea-shore. The rafts which are used by the fishermen and others at Madras consist of three logs of timber, each eight or ten feet long, which are lashed together. With these rafts the rowers pass through the surf to fish, or to convey refreshments to ships when no boat could venture off. On the coast of South America the rafts are of considerable size, being made of trunks of trees from 70 to 80 feet long, lashed together, and being from 20 to 25 feet wide: the middle trunk is longer than the rest, and projects beyond them at the after extremity. They carry sails on masts resembling shears; and they are steered by raising or lowering, as the occasion may require, a board which enters vertically between the timbers either at the fore or after part of the raft.

CATAPLASMS, or poultices, are substances applied externally to different parts of the body, either to allay pain and repress inflammation, or more frequently to promote inflammation or its consequences, and lessen the pain attending it. For the former purpose they are

applied cold and generally contain a preparation of lead; for the latter they are of different degrees of temperature. When it is intended to hasten the progress of inflammation so as to lead to suppuration, poultices should be of as high a temperature as the part will bear, but of a lower temperature when they are used as mere emollients. The material of which the poultice is made influences its action, but those are best which have the power of retaining heat and moisture for the greatest length of time. The meal of linseed, especially if the oil has not been expressed previous to reducing the seeds to powder, is the best for all common purposes; but John Hunter complained that this, and all poultices, were generally made too thin. For application to a limited space, such as the lip or eyelid, a roasted apple or fig is best; and a roasted onion is the most suitable application to a boil. Poultices are seldom changed with sufficient frequency. A fresh poultice should always be applied before the one before it has become cold, when the object is to expedite the maturation of a swelling and bring about suppuration. When the surface is broken and suppuration going on, it is not necessary to change the poultice so frequently, as it is desirable to exclude the air as much as possible. To cleanse ulcers, the carrot poultice is a good application, and when there is much irritability or fœtor, the yeast poultice, or one containing charcoal finely powdered are good, but chloride of soda or zinc is better than either. Manganate of potash is also good. [DISINFECTANTS.] The face of a poultice is often coated with oil, and sometimes powdered camphor or red bark may be sprinkled on it, according to the object in view.

CATAPULTA. [ARTILLERY.]

CATARACT (Gr. *καταράκτης*, in its most common sense, "a fall of water over steep rocks," also, "a door that shuts to," "a bolt, barrier, or obstruction," from *κατα(ρ)-ρύπτειν*, to break down or interrupt), is an opacity of the crystalline lens or its capsule, which obstructs the transmission of light to the retina, and, according to its degree, impairs or destroys the sight.

To understand its nature, and the means adopted for its cure, the following anatomical facts must be borne in mind. The *cornea* or front of the eyeball is a tough, transparent, and slightly protuberant shell, firmly united to the *sclerotic* coat or white part of the eye. Immediately behind the cornea is a space filled by a watery fluid, the *aqueous humour*, in which the coloured *iris* is suspended like a screen. This membrane, attached by its outer edge to the sclerotic near its junction with the cornea, has the power of contraction and expansion, so as to limit the admission of light through its central opening called the *pupil* to the amount best adapted for vision. Behind the iris and nearly touching it is the *crystalline lens*, inclosed in a transparent membranous capsule, which is attached to what are called the *ciliary processes* behind the external border of the iris. The narrow interval between the lens and *uvea* or posterior surface of the iris is called the *posterior chamber*; the more ample space which separates the iris from the cornea is called the *anterior chamber*. The crystalline is a transparent sticky substance of high refracting power, firmer towards the centre or nucleus, more soft as it approaches the capsule, to which it very slightly adheres. It is nearly flat in front, and swells out behind into a considerable convexity imbedded in a corresponding hollow of the *vitreous humour*. This fluid fills up the remaining space in the globe; it is inclosed in a pellucid membrane termed the *hyaloid*, and seems to consist of water contained in the interstices of a fine cellular structure, which, dividing it into separate portions, gives it a semi-gelatinous consistence. The delicate expansion of the optic nerve called the *retina* is placed, like a cup with the concavity forwards, immediately behind the hyaloid, the edges advancing as far as the attachment of the capsule of the lens; it consequently incloses the whole of the vitreous humour.

The disease we are now in a condition to describe is divided into *true* and *spurious* cataract. The latter term is applied to an obstruction which arises from an opaque film of purulent lymph thrown out by inflammation between the uvea and the capsule, often producing adhesion between these parts, and passing like a gauze blind across the pupil. The usual means which control inflammation in other cases may be used in this, and sometimes effect a cure, but no operation is applicable to it; it may arise from injury, and occurs occasionally in gout and rheumatism, and in some forms of secondary syphilis. The ancients appear to have considered all cataracts to be of this nature.

True cataract is of three kinds: *lenticular*, when the opacity is confined to the lens; *capsular*, when the capsule only is affected; and *capsulo-lenticular*, when both structures participate in the disease. The term, when used simply, is to be understood of the lens itself.

Lenticular cataract.—An important practical division of this complaint is into the hard and soft kinds. The former is the most frequent, and is the variety usually met with in advancing age. Though called *hard* for the purpose of distinction, it may have any consistence, from that which is natural to the part, or less, to the tenacity of wax. The opacity generally begins in the nucleus behind the centre of the pupil, and is at first of a bluish-white colour, like milk and water. This gradually spreads towards the circumference, the nucleus in the mean time assuming an amber-coloured or brownish hue, which sometimes becomes as dark as mahogany, and may extend through the whole lens. The firmness of the cataract is found to bear a close relation to the depth of the tint. Both eyes may be affected at once, but hard cataract more commonly begins in one eye; and after a

certain time, from a few months to several years, the other becomes affected in the same manner, and all useful vision is thus eventually destroyed. In this kind of cataract the lens is almost always diminished in bulk, so that upon examination it may be seen to lie at some distance behind the pupil, the movements of which remain free and unembarrassed.

Soft cataract is more frequently single, and prevails in childhood, and the middle period of life. In this form of the complaint the lens, instead of shrinking, commonly enlarges, so as to obliterate the posterior chamber, and press the iris forward towards the cornea. Its texture is everywhere changed and softened: it may be converted into a turbid fluid, in which case the more opaque particles are sometimes observed to subside during rest; or it may have the consistence of soft cheese. The opacity, often streaked and mottled at first, is also general from the commencement, and is found to occupy the whole pupil, even when dilated to the utmost by artificial means. The discoloration varies in shade from a mere cloud to the whiteness of milk; and in the latter case the light is more completely intercepted than by the darkest hard cataract, which always retains a degree of horny transparency, admitting, for instance, the distinction of shade from sunshine; whereas, in the most opaque soft cataract light can barely be distinguished from darkness.

There is a kind of central opacity more allied to the soft than the hard species, in which the affection is confined to the nucleus, and sometimes circumscribed to a mere speck in its centre, the rest of the lens remaining transparent. This affection is most frequently met with in infancy, if it be not absolutely confined to that age.

Capsular or membranous cataract commonly appears in specks or streaks of a pearly or chalk-white colour, without the bluish tint which prevails in the early stages of both the former kinds, and more frequently affects the anterior layer of the capsule than the posterior. In the former situation it is close to the pupil, and is plainly convex; in the latter it is concave, but it is not so readily distinguished, as it lies deeper and is seen through the lens, itself usually opaque at the same time: indeed some have doubted the separate existence of opacity in the posterior layer of the capsule, and it is certainly by no means so frequent as in the anterior layer.

Capsulo-lenticular cataract, or that in which both structures are implicated, is much more common. In such cases the lens is usually in the softened state already described. Congenital cataracts are generally of this nature; the opacity, if not *central*, being uniformly diffused, and the consistence never greater, and usually much less than in the healthy state. It frequently prevails among members of the same family; and has a peculiarity which renders an early performance of the operation of essential importance. This consists in a constant rolling and unsteady motion of the eye-ball, which may become habitual, and preclude the patient from ever acquiring the power of directing the eyes at will towards an object. The capsular varieties, especially those which commence in the anterior layer, are more frequently the result of injury, and complicated with inflammatory conditions of the constitution or of the eye itself, than those in which the opacity is confined to the lens. These last, especially the hard cataracts of advanced life, are often strictly local affections, and can neither be classed with inflammatory disorders, nor traced to any constitutional cause.

The symptoms experienced by a person affected with cataract may readily be imagined. The symptom first perceived is a dim haziness of sight, as if a mist or a thin veil were interposed between the object and the eye. The obscurity is greatest in direct vision; in hard cataract, because the opacity is originally central; in soft, because the direct rays pass through the thickest part of the lens, while those which enter laterally are transmitted nearer to the edge, which is comparatively thin. The sight is better, for the same reason, in weak light, and with the back turned to the window, than in strong light: for the pupil in the latter case is contracted, and permits the passage of the rays only through the middle of the lens. Hence also the advantage derived in all cases from dropping the juice of the belladonna or deadly nightshade into the eye, which with some other sedative vegetable poisons, has the remarkable property of dilating the pupil by some specific action on the iris independently of the retina. It is a curious circumstance that this effect is not impaired by repeated applications.

None of the varieties of true cataract are subject to the influence of any known medicinal remedy, whatever may have been put forward to the contrary to serve interested purposes: nor is it at all likely that any remedy exists with powers capable of acting upon parts so obscurely organised, and so completely out of the course of the circulation. No vessels have ever been discovered in the lens under any condition of that part; and it is probably as little endowed with vitality as the hair and nails. Consequently, all the palliation the case admits of is limited to the local application of belladonna, attention to the general state of the health, and care in removing the inflammatory symptoms, with which, as we have seen, it is sometimes complicated. A radical cure can only be brought about by the actual removal of the cataract.

Much difference of opinion has existed as to the most eligible way of effecting this object; but it is now well understood that each of the methods proposed may be the best in its turn, and that the point can only be determined by the circumstances of the particular case.

All the operations for cataract may be classed under three heads, as they are calculated to effect, either its extraction; its displacement from the axis of vision; or its absorption or solution.

Extraction is commonly effected in the following manner:—A fine triangular knife, sharp at the point and the oblique edge, and having the back in a straight line with the handle, and the flat of the blade towards the eye, is steadily and quickly passed through the upper or lower half of the cornea, as near to the iris as possible without touching it. A needle slightly curved at the point is insinuated under the flap thus formed, and brought to bear upon the front of the capsule so as to lacerate it; upon gentle pressure of the globe the lens slips out of the capsule, and easily distending the pupil escapes through the wound in the cornea, which soon heals in favourable cases, and the sight is restored. Spectacles suitably convex must afterwards be worn as a compensation for the refractive power of the lens. This operation is chiefly suited to the hard cataract and the adult age. It is inexpedient in gouty and inflammable subjects, and when the eye is either too prominent or too deep in the orbit.

Displacement of the lens from the axis of vision, which was the method practised by the ancients, is effected in several ways; the most usual is that called depression or *couching* (from the French *coucher*, to lay down). A sharp needle, with edges which cut a little way from the point, is introduced perpendicularly through the sclerotic, near its junction with the cornea, and consequently behind the lens; the pupil having been previously dilated by belladonna. The point is then brought forward through the lens, which, by a backward and downward movement of the hand, is drawn out of its place behind the pupil, and lodged under it in the vitreous humour. The opaque body being thus removed, the sight immediately returns; but as the lens may partially rise again into its place, it is often necessary to repeat the operation at intervals, which has been done a dozen times with perfect eventual success. The lens does not produce so much irritation in its new situation as might naturally be expected, and it is commonly absorbed in part or wholly in the course of time. This method of operating is not very frequently resorted to in the present day.

The third kind of operation, which is intended to cause the absorption of the lens, or its solution in the aqueous humour, is performed much in the same way; but instead of drawing the needle backward, the operator pushes it in through the lens into the pupil, and lacerates the anterior capsule. The aqueous humour is thus admitted to act upon the cataract, which, perhaps, after several repetitions of the operation, becomes absorbed or dissolved, and vision is thus restored. This mode of operating, with variations which need not be detailed, is generally adopted in soft cataract, and always in congenital cases.

It is not only necessary that much discretion should be exercised in the choice and execution of the operation; it must in all cases, more especially in extraction, be preceded and followed by means calculated to prevent inflammation, which often occurs in spite of all precautions, and may render the operation worse than useless. It is not usually thought expedient to operate on one eye while useful vision remains in the other; nor by the method of extraction in both eyes at the same time: nor is an operation warrantable when the patient cannot distinguish light from darkness, which proves that some other cause of blindness exists independently of cataract; nor if the iris or other membranes in front of the crystalline be disorganised by previous inflammation. Many other cases might be enumerated in which an operation is of questionable propriety. On the whole, however, cataract may thus be cured, and useful or even perfect vision restored in a large proportion of cases. The pain of the operation itself is very inconsiderable, nor does any disfigurement or inconvenience arise if it be skilfully performed.

CATARRH, or CORYZA, that is, catarrh in the strict sense of the term, commonly called cold, consists of inflammation of that portion of the mucous membrane of the air passages which lines the nostrils. Inflammation, though often strictly confined to this portion of the lining membrane, when it gives rise to the symptoms known under the name of common cold, or coryza, is very apt to extend beyond the nostrils, when it produces other diseases which are distinguished by different names: when, for example, the inflammation extends from the nostrils into the frontal sinuses, pain, and a sense of weight in the head being superadded to the symptoms of coryza, the affection is called *gravedo*, *catarrhal headache*, or cold in the head; when inflammation extends to the back part of the throat, the affection is called *cynanche catarrhalis*, or *catarrhal sorethroat*; when to the larynx, *laryngitis*; and when to the bronchi, *bronchitis*. [BRONCHITIS.]

The symptoms of coryza are a sense of uneasiness, fulness, heat, and stuffing in the nostrils, frequent sneezing, diminished acuteness or total loss of the sense of smell, together with a slight impediment to the respiration, occasioned by the impeded transmission of the air through the nostrils to the lungs, in consequence of the swelling of the membrane, the degree of the swelling being always in proportion to the severity of the inflammation. [BRONCHITIS.] Though the main seat of inflammation in coryza is always in the lining membrane of the nostrils, yet very constantly a sufficient degree of it extends to the frontal sinuses to occasion some uneasiness there, inducing a sense of fulness, heat, weight, and even pain across the forehead. Occasionally, too, the membrane which lines the tube through which the tears pass

into the nose becomes so much swollen that the tears cannot enter it, and consequently flow over the cheek; while the external membrane which is reflected over the eye itself participates in the inflammatory affection, and becomes reddened and painful.

These local disorders are often the only symptoms which exist; but whenever the disease is severe, the system becomes affected, and then to these local symptoms are superadded indications of a general disturbance in the economy. These general disordered functions are uniformly those which indicate a feverish condition of the system, namely, chilliness or coldness succeeded by heat, dryness of the skin, lassitude, stiffness, or a sense of uneasiness, often amounting to pain, in the back and limbs, together with a greater or less degree of headache.

The dryness of the membrane affected, in coryza, the first consequence of inflammation, from the suppression of secretion, gives rise to the irritation, the itching, and the sensation of heat in the nostrils, and more particularly at their entrance. Next comes the acrid fluid already described [BRONCHITIS], which flowing upon the upper lip and the anterior portion of the nostrils, irritates and excoriates them, and which, passing by the posterior nares into the pharynx, and thence upon the epiglottis and glottis, occasions violent cough; and last of all flows the bland fluid, with the immediate subsidence of all irritation. [BRONCHITIS.] The causes of coryza are precisely the same as those of bronchitis.

Of all the diseases to which the human body is subject, catarrh is the most frequent, at least in this climate, which is subject to such sudden and great changes of temperature, and where the atmosphere is so often loaded with moisture. Scarcely an individual passes through the year without suffering from it in a greater or less degree. Fortunately its danger is by no means proportionate to its frequency. It is never of itself fatal excepting in the very young and in the very old. But inflammation of the mucous membrane of the nostrils, however slight it may be at first, is very apt to spread to other portions of the membrane, to become severe, and consequently to occasion serious disease. It is the constant source of bronchitis, it often terminates in inflammation of the substance of the lung, and it frequently lays the foundation for consumption. Hence whenever there is the slightest appreciable predisposition to disease of the lung, a common cold, in however mild a form it may come on, ought to be attended to with anxious care. Every year many persons apparently in good health at its commencement are dead before its close, in consequence of two or three days' neglect of a cold.

The disease, at first local in its seat, may often be cured at once, or at all events its severity may be lessened and its duration shortened by the application of a local remedy; such as the inhalation through the nostrils of the vapour of warm water, or what, perhaps, is more effectual, the vapour of an infusion of chamomile flowers, or of a decoction of poppy-heads. The steam from these heated fluids should be made to pass through the nostrils for at least the space of a quarter of an hour or twenty minutes at a time. It is important that the temperature of the apartment be maintained uniformly at a moderate degree, about 65°, the sleeping as well as the sitting-room. With a view of determining to the skin, so as to produce a general and gentle perspiration, the feet, immediately before going to bed, may be bathed for twenty minutes in warm water, and the bed warmed. A tumbler full of wine-whey, or a basin of warm gruel, will promote the perspiration, and under this simple treatment the patient will often arise in the morning without the slightest remains of the disease. A mild aperient may be often added with advantage.

When there is any degree of fever, the treatment must be the same as in bronchitis.

CATCH, in music, a composition of the humorous kind for three or four voices, which owes its origin to this country, and does not appear ever to have travelled out of it. It is a song of as many verses or couplets as parts. The highest part is first sung through alone; the singer of this goes then to the second part, the second voice takes the first, &c., and thus each performer sings through all the parts in succession, and, generally, three times over. The *catch* depends on the distribution of the words among the performers. This is so contrived that a meaning is given to the lines wholly different from that which appears when they are read in a straightforward manner. The catch in "the good old times" was often obscene and disgusting. Among other improvements in manners the abolition of such offensive productions deserves to be mentioned here. Some good catches, however, but of later date, by Webbe, Calcott, &c., remain, which are exceedingly facetious, and such as may be, and are, introduced at any social meeting with propriety.

CATECHIN = TANNINGENIC ACID ($C_{40}H_{18}O_{16}$) is that portion of catechu which is insoluble in cold water. It is soluble in hot water, and crystallises in the form of a white silky powder. When heated with caustic potash it yields a black acid, called *japonic acid* ($C_{12}H_5O_5$). Carbonate of potash produces with it *rubinic acid*, or *rufocatechucic acid* ($C_{18}H_6O_4$), which has a red colour. [TANNIC ACIDS.]

CATECHINUM, *Medical properties of.* This peculiar principle is obtained not merely from catechu, strictly so called, but also from gambir and some kinds of cinchona bark. Certain slight differences are found in it, according to the source whence it has been obtained, such as that from catechu having no acid reaction on litmus, while the

others have. The best mode of procuring it is to digest catechu in sulphuric ether, then evaporate the ether, wash the residuum in cold water, repeatedly dissolve it in boiling water, and by renewed evaporation procure it pure. The appearance is that of a white semicrystallised powder (resembling magnesia or grape-sugar), with an astringent taste, which is followed by an unpleasant and somewhat sweetish one. It is persistent at the ordinary temperature of the air, but by long exposure to damp it resolves into a mould-like mass; at a moderate heat it melts into a transparent fluid; by a strong heat it becomes brown.

Of hot water it requires only from three to four parts for its solution, but of cold 16000: of boiling alcohol from two to three, of cold from five or six parts for its solution; of boiling ether it requires seven to eight, while of cold it needs a hundred and twenty for its solution. It is one of the most delicate tests of some of the salts of iron (when these are devoid of any free acid), as it strikes a most beautiful dark green colour, without precipitation; which colour results if there be but $\frac{1}{50000}$ part of iron in solution, only the kind obtained from the *Nauclea gambir*. It does not precipitate either a solution of gelatine or of starch, a peculiarity which distinguishes it from tannin; and which constitutes its claim to attention as a therapeutic agent, as a means of arresting hæmorrhage in distinct organs. Pure tannin is almost certainly precipitated by the starchy or gelatinous principles it meets with in the food in the primæ viæ, and has therefore little influence on hæmorrhage from remote organs. All who know the difficulty of checking the flow of blood in those of hæmorrhagic diathesis, especially from leech-bites, scarification of the gums, &c., will be glad to have a new resource in catechin.

CATECHISM. Almost all our ecclesiastical terms are of Greek origin, and almost all of them may be traced to some word or some expression in the sacred writings. It would perhaps hardly be expected that to *catechise* comes from a Greek compound word denoting the reflection of sound, *κατηχέω*, the reverberation of the voice; yet such is the fact; and the reason that this word has established itself in ecclesiastical affairs to denote the mode of instruction by question and answer without book, which is what is properly meant by catechising, is that Saint Paul has used the word in his First Epistle to the Corinthians, xiv. 19, "that by my voice I might teach others," *κατηχήσω*. The word occurs also in other passages of the Sacred Scriptures, denoting instruction in affairs connected with religion.

Catechising then, etymologically, and according to the primitive usage, is delivering orally instruction in matters pertaining to religion. Whether in this there was anything in common with the notions which seem to have pervaded some of the ancient systems of divinity, that the mysteries were not to be committed to writing, but only handed down traditionally from age to age, may be doubted, since the practice is so easily explained on what is a mere common-sense principle. Christianity was to present herself to innumerable persons who could receive its truths by the hearing of the ear, while they were unable to peruse any writings in which it might be presented to them. Such persons there have always been in every Christian community, and we are quite sure that when the Christian missionaries addressed themselves to nations but a little removed from a state of barbarism, this mode of instruction was the only mode in which what it was necessary for them to know could be communicated. In such a state of society also their answers to a few simple questions, which they would easily learn by frequent repetition, would be accepted as a sufficient profession of faith entitling them to baptism, confirmation, or a participation in any Christian ordinances. In the early church *catechumens* were not admitted to the sacrament, to public prayers, nor to ecclesiastical assemblies, until they had received baptism.

What, in the infancy of Christianity, was the mode of communicating the elements of Christian truth to persons of all ages, has become in process of time the mode of making such communications to the minds of children only. The reason is obvious: we have now seldom any adults who come with minds wholly unfurnished with the elements of Christian truth; children are therefore almost the only persons who now need catechetical instruction. We do not speak of the few instances which society even in this country does occasionally present of persons brought up in utter ignorance of religion and its truths and duties. But children, generally speaking, are now the only persons who need this kind of instruction; and when we use the terms *catechise* and *catechumens*, which last word denotes the persons placed under this mode of religious instruction, we refer them at once to children, and children only. The more wide extension of the ability to read has rendered this mode of introducing to the young the knowledge of Christian principles and duties of less importance, though it is still considered a part of pastoral duty belonging to the Christian minister to catechise the young of his flock, and thus to prepare them for the ceremony of confirmation. To say the least, it is an impressive mode of communicating the elements of Christian truth, and it serves throughout the period of after-life to cement an attachment which it is desirable should always exist between the individuals of a Christian flock and their pastor. The greater extension of the ability to read has also produced another change. Catechisms originally intended for the use of the instructor have been transferred to the instructed, who have learned in them the answers which beforetime they were wont to have only from the mouth of the teacher. By far the most celebrated

among ourselves of these catechisms is that which is incorporated in the Book of Common Prayer, an intimate acquaintance with which is held to be essential to every person who is a candidate for confirmation. Innumerable other catechisms have been printed, both at home and abroad, in some of which, however, though they are called catechisms, we recognise but faintly the impression of the peculiar character of this mode of instruction, they being rather bodies of Christian divinity exhibited in the form of question and answer. This is the case with the Racovian catechism, which contains the doctrines of the Polish Socinians. This is the case with the Genevan catechism, which exhibits at much greater length than we can suppose to have been designed to be committed to memory, the principles of Christian truth as professed by the pastors of that city. The Assembly of Divines at Westminster, who, at a time when Presbyterianism was in the ascendant in England, were called together to devise a new form and order of Christian profession, put forth two catechisms: a larger, containing a system of Christian doctrine, with the evidence on which its several parts were supposed to rest; and a smaller, which was intended for the actual catechetical instruction of the young. Both these present a system commonly called Calvinistic.

Catechism is also frequently used now for any system of teaching by question and answer. Thus, we have catechisms of history, geography, chemistry, &c.

CATECHU. The inspissated extract of the *Acacia catechu* is known by this name; but as there are several varieties of this substance, it is probable that it is procured from other species of this genus, as indeed is positively stated by Dr. Wallich, who denies that any catechu is obtained from the *Areca catechu*. Geiger affirms that one variety of catechu is the extract of *Nauclea gambir* (Hunter), which however is generally considered to yield a sort of kino, but it is called gambir. It comes from Singapore. (See Nees von Esenbeck, in Buchner's 'Repert.', vol. xxii., p. 185, and Dierbach, in 'Magaz. für Pharmacie,' vol. xvii., p. 106.) The specific gravity differs, that of Bombay being 1.39, while that of Bengal is only 1.28, also their reaction with iron.

At the season of the year when the sap is most perfectly elaborated, the bark of the *Acacia catechu* is removed, and the tree cut down, the outer white part removed, and the remaining brown heartwood cut into such pieces as can be conveniently introduced into a narrow-mouthed vessel; water is poured in, and then boiled down to one-half the original quantity; the further inspissating is conducted in wide earthen vessels. It is then allowed to stand in the sun, frequently turned, and at last transferred to cloths strewed over with the ashes of cow's dung, and cut into four-square pieces, which are then thoroughly dried in the sun. The darker the wood from which it is obtained, the darker the colour of the extract: it has so much the appearance of a mass of earth as to have been once considered such, and called *terra japonica*. The farina or meal of a seed resembling wheat, and called *nachani*, is often mixed with it, not as an adulteration, but to prevent the soft masses adhering to each other.

Catechu occurs either in irregular pieces or in small cubes, of a dark brown colour; odour very faint; taste powerfully astringent, afterwards bitterish, then sweet. It is nearly completely soluble in water, more perfectly in alcohol. Analysed by Sir H. Davy—

	Bombay catechu yielded	Bengal yielded
Tannin	109	97
Extractive	68	73
Mucilage	13	16
Impurities	10	14

The Bombay variety is preferable: it is a valuable astringent, and may be employed either to act immediately on the mucous membrane of the digestive organs, or on remote organs. In all cases of relaxation of the tissues, either accompanied with a flow of blood or increased mucous discharges, or without any obvious discharge, catechu renders great assistance in restoring the parts to a healthy condition. In relaxed uvula or pap of the throat, causing irritation and cough, a portion of catechu melted slowly in the mouth is extremely useful. In diarrhoea, from debility, catechu alone, or combined with prepared chalk and opium is much employed, though chemists disapprove of the combination, on the ground that an inert tannate of lime is formed. It is found however to be practically advantageous. Where the debility is great, aromatics and cordials may be added, provided there be no inflammatory condition of the intestines, a point which should always be most carefully inquired into before administering astringents. [ASTRINGENTS.]

CATECHUIC ACID. [TANNIC ACIDS.]

CATECHUTANNIC ACID. [TANNIC ACIDS.]

CATEGORY, the word *κατηγορία* (*κατεγορεύειν*, to declare, aver), was used by Aristotle in a manner on which much discussion has arisen (See Mansel's edition of Aldrich, 'Appendix,' note B). Mr. Mansel considers that the distinction arose from the resolution of the proposition, and a classification of the grammatical distinctions indicated by its parts. Thus, taking the Greek terms, presently translated, the noun substantive leads to the category of *οὐσία*, the adjectives of number and quality to *ποσόν* and *ποιόν*, the adjectives of comparison to *πρός τι*, the adverbs of place and time to *πού* and *ποτέ*, the different forms of the verb, intransitive, præterite, active, and passive, to *κείσθαι*, *ἔχειν*,

ποιεῖν, and πάσχειν. With this account of the probable derivation we agree.

Aristotle's book of Categories is the first of the six which compose the 'Organon.' By the scholastic authors, Curio, Tonstius, Vives, and others, it is asserted that this book of Categories was written, not by Aristotle, but by the peripatetic philosopher Andronicus, who revised and published the works of Aristotle in the 1st century B.C. There appears to be little foundation for this opinion, since Ammonius, Simplicius, Boethius, and others, in their commentaries on it, indicate no doubt of its genuineness; and the reason for doubt assigned in the analysis of Aristotle's Logic by Dr. Reid in his 'Intellectual Powers,' 1827 (inserted also in Lord Kames's 'Sketches'), namely, an inconsistency in the doctrine of the book of categories, and that of the books of analytics, is not founded on fact; though such misconception might well occur about the meaning of the first chapters of the categories, in which so much subtle and abstruse definition is occasioned by the Greek language having but one word οὐσία (ousia), to express 'substance' (all the essential and accidental qualities of an object) and 'essence' (all the essential qualities only). Aristotle's frequent mention of the book of Categories, and above all, as Mr. Taylor in his translation remarks, the obscurity and difficulty of the sentences, and the involved diction, are evidence that Aristotle is the author. But similar classifications were formed before the appearance of the 'Organon.' In a treatise by the Pythagorean philosopher, Archytas of Tarentum, entitled περὶ τοῦ παντός (concerning the universe, or, as Taylor says, universal terms), the arrangement adopted by Aristotle was set forth and discussed. Through Plato, the disciple of Archytas and preceptor of Aristotle, the theory of the Aristotelian Categories descended from the school of Pythagoras, in whose system 10 was a number replete with sacred mystery ('Denarius Pythagoricus,' by Meursius, c. 12; and 'Pythagorean Decad.,' in 'Theoretic Arith.,' by T. Taylor, c. 12). The work of Archytas is copiously cited in the commentary of Simplicius on the ten Categories. The extant fragments were also published separately in 1571, 8vo., Venice. Archytas and the other Pythagoreans considered these ten universal ideas as the principles of all things—the causes of the universe,—a doctrine which requires for explanation a reference to the Pythagorean and Platonic theory of ideas. By Aristotle and the peripatetics in general they were proposed merely as comprehensive forms of predication, by which the perplexing variety of human ideas were supposed to be conveniently arranged for the use of the dialectician. All the objects and modes of human thought were thus distributed as species under ten *summa genera*, or universal terms, to facilitate a comprehensive survey of the τὸ πᾶν, the whole physical and metaphysical world, known and unknown. The names of the ten Categories, as enumerated by Aristotle ('Cat.' c. 4, and 'Top.' l. i. c. 9) are: 1, οὐσία or τί ἐστὶ; 2, πόσον; 3, ποῖον; 4, πρὸς τί; 5, ποῦ; 6, πότε; 7, κείσθαι; 8, ἔχειν; 9, ποιεῖν; 10, πάσχειν; which are variously expressed in English by different writers. In Dr. Whately's Logic they are rendered as follows: "substance, quantity, quality, relation, place, time, situation, possession, action, suffering;" but to perceive the meaning of the Greek terms, it must be observed what Aristotle comprehends under each of these general designations: ἔχειν, for instance, is said to signify the having something attached to the person; to be "booted, armed" (τὸ ἔχειν σημαίνει τὸ ὑποδεέσθαι, τὸ ὠπλίσθαι 'Cat.' c. 9); but in the last chapter of the Categories eight modes of having are enumerated. The first four categories, namely, 'οὐσία, πόσον, πρὸς τί, ποῖον,' are elaborately explained by Aristotle in four long chapters; the definition of the remaining six is despatched in a word or two, but the nature and properties of all are more fully defined incidentally throughout the rest of his works. That they are classifications only of words was maintained by some of the ancient philosophers ('Philos. Arrangements,' by Harris, p. 16). Concerning the question whether these universals are real existencies or merely names or conceptions, see the remarks on the Realists and Nominalists in Dr. Reid's 'Essays,' c. 5 and 6. In the later ages of Latinity these Categories were denominated prædicaments; the name by which they have since been generally designated in the scholastic works on logic, in which they are usually translated and placed as follows: "substantia, quantitas, qualitas, relatio, actio, passio, ubi, quando, situs, habitus," and illustrated by the following jargon as an aid to memory.

"Arbor, sex, fervore, patres, refrigerat, ustos,
Ruri, eras, stabo, nec tunicatus ero."

As to the utility of these ten Categories, it may be remarked that they were made to form an essential part of the mediæval system of logic, which was rejected as useless by many of the principal philosophical writers of the last three centuries, such as Bacon, Hobbes, Descartes, Locke, Condillac, Reid, Kames, Stewart, Brown, De Stutt Tracy, &c. But they do not properly belong to logic at all; and those who rejected logic, and those who maintained the logical character of the categories, fight with each other a battle in which modern opinion sides with neither. It was affirmed that the categories were used but to maintain among the illiterate the reputation of universal knowledge; that they served only to support syllogistic argumentation for victory, and supplied a convenient ready-reckoner, by which a prompt solution could be given even to questions beyond the reach of human knowledge, and in reality quite unanswerable. The lovers of satire may

turn to Gassendi's 'Exercitationes adversus Aristoteleos,' where the ten Categories are unsparingly treated. The remarks of Hobbes in his Logic ('Opera Philosophica,' 4to, 1688) are no less satirical: "Fateor me prædicamentorum usum hactenus non magnum perspexisse; cepit opinor Aristotelem libido quædam pro autoritate sua, cum rerum non posset, verborum tamen censum peragendi," p. 16. So the authors of the 'Port Royal Logique, ou l'Art de Penser' (Nicole and Arnauld), p. 21, "Voilà les dix Catégories d'Aristote, dont on fait tant de mystères—à dire le vrai, c'est une chose très peu utile—toute arbitraire, et qui n'a de fondement que l'imagination—elle accoutume les hommes à se payer de mots; à s'imaginer qu'ils savent toutes choses, lorsqu'ils n'en connaissent que des noms arbitraires:" and De Stutt Tracy, 'Logique,' p. 22, "Cela n'est utile absolument à rien." It would be endless to quote similar opinions from the best modern works on the subject. On the other side, among the defenders of the Categories are Monboddo, Harris, Gillies, and T. Taylor. Harris, in his elaborate work on the subject ('Philosophical Arrangements,' p. 34), says "The doctrine of these Categories is a valuable, a copious, a sublime theory—a theory which prepares us to study every thing with advantage:" p. 462, "There are few theories so great, so comprehensive, so various, as the theory of these Categories: in contemplating them we see whence the sciences and arts all arise—history out of substance; mathematics out of quantity; optics and medicine out of quality and quantity; astronomy, music, and mechanics, out of quantity and motion; painting out of quality and site; ethics out of relation; chronology out of when; geography out of where; electricity, magnetism, and attraction out of action and passion," &c. In the Categories of Kant ('Kritik der Reinen Vernunft,' 7th ed., 1828), the precise boundaries of human knowledge, *a priori*, are professed to be exhibited; these Categories consist of four primordial classes: 1, quantity; 2, quality; 3, relation; 4, modality; each class containing three Categories: 1, unity, multitude, totality; 2, reality, negation, limitation; 3, substance and accident, cause and effect, action and reaction; 4, possibility, existence, necessity.

That in treating of extensive subjects, some similar methodical classification is very useful and necessary for perspicuity and brevity, is obvious. A tabulated view of Locke's arrangement of ideas (his Categories, as they are sometimes named) is given to great advantage on a large sheet prefixed to the edition of his Essay in 1828. Among the ancients different names and numbers of categories were adopted by different sects: by Aristotle and the peripatetics they are variously called καθόλου λόγοι, universal terms; σχήματα κατηγορίας, forms or figures of predication; κατηγορίαι, categories; γένη γενικώτατα, the most comprehensive genera; τὰ πρῶτα δέκα γένη, the ten primary genera. Plato reduces them to five; namely, οὐσία, ταυτότης, ἐτερότης, κίνησις, στάσις; substance, identity, diversity, motion, rest. The stoics made four: namely, ὑποκειμένα, ποῖα, πῶς ἔχοντα, πρὸς τί πῶς ἔχοντα; subjects, substances, modes of being, relative modes of being. Some philosophers have preferred seven: namely, spirit, matter, quantity, substance, figure, motion, rest: others three, namely, subject, accident inherent, accident circumstantial; others make only two, simply, substance and attribute, or subject and accident. Other philosophers arrange all existent things under the following six categories:

"Mens, mensura, quies, motus, positura, figura,
Sunt, cum materia, cunctarum exordia rerum."

Cicero and Quintilian name the ten Categories of Aristotle 'Elementa Dialectica.'

(See Ammonius, *Comment. in Categ. Græcæ*, 12mo, Venice, 1545; same in Latin by Silvanus, Paris, 1542; Simplicii *Comment. in Prædic. Aristot.*, fol. 1567; *Analysis of Aristotle's Works*, by Dr. Gillies, 4to, p. 58, *et seq.*; Monboddo, *Origin of Lang.*, vol. i. p. 317, *et seq.*; vol. v., p. 416; and *Antient Metaphysics*, vol. i. pp. 26, 311, 329; Boethii *Aristot. Dialect.* fol. 1560, p. 106, *et seq. in Categor.*; Stewart's *Elem. Philos. Mind*, vol. ii., on *Aristot. Log.*; *The Organon, Comment.* by Pacius, 4to, 1605. The English translation by T. Taylor, 4to, 1812, contains the substance of all the chief Commentaries.

CATENARY (from *Catena*, a chain) is the curve in which a string of perfect flexibility and uniform thickness and density will hang from two points, which we may suppose to be in the same horizontal line, as the nature and properties of the curve will be the same from whatever points it may hang. And all catenaries are similar curves; that is to say, let there be any number of such curves formed by chains of different lengths, then each of them will be a picture, on a reduced or enlarged scale, of some portion of the longest.

Various properties of catenaries have been investigated, in cases where the thickness or density of the string are variable. See in particular Creswell's translation of Venturoli's *Mechanics*, and Whewell's *Analytical Statics*. We shall here confine ourselves to the most common properties of the catenary, which, with the modifications always required when we come to apply the mathematics of a flexible and inextensible chain to the materials of the architect, is the first step towards the theory of the suspension bridge. Let *c* and *p* be the two points of suspension, *c a d* the chain, of which *a* is the lowest point, and *a b* a vertical passing through it. Let the units be inches and ounces (any others might be used), and let the weight of the chain be *k* ounces to the inch; let *l* be the length of chain equivalent to the tension at *a*, and *r* that equivalent to the tension at *p*, a point whose

abscissa is AN or x , and its ordinate NP or y . Let the length of the arc AP be s , and the angle $NT P$ be θ . Let Aa be made equal to t inches, and through a draw a horizontal line ap . Hence if CA were taken away,

and the chain suffered to hang over a fixed point at A down to a , the part DA would not alter its form. And it is the most striking property of the curve, that if the portion DP above any point P were taken away, and the chain suffered to hang over a fixed point at P down to the same horizontal line ap , the part $CA P$ would be maintained by the portion Pp in its position.

The following are the equations which connect T , t , x , y , s , and θ :

$$T = t + x = \sqrt{s^2 + t^2}, \tan. \theta = \frac{t}{s}$$

$$s = \sqrt{2tx + x^2} = \frac{t}{2} \left(\epsilon^{\frac{y}{t}} - \epsilon^{-\frac{y}{t}} \right)$$

where $\epsilon = \text{base hyp. log.} = 2.7182818 \dots$

$$y = t \text{ hyp. log. } \left(\frac{x}{t} + 1 + \sqrt{\frac{x^2}{t^2} + \frac{2x}{t}} \right)$$

Given the distance between C and $D = 2c$, and the length of the whole chain $CAD = 2l$, then the value of θ at the point D , supposing a tangent drawn there, must be found by approximating to a solution (θ being unknown) of

$$\frac{c}{l} = \tan. \theta \text{ hyp. log. cot. } \frac{\theta}{2}$$

which might be solved by inspection, if a sufficient table of the values of the second side were formed. The extreme value of θ being thus found, which call λ , t is found from $t = l \tan. \lambda$, and thence the tension at any point of the curve can be found; and AB , which call h , is found from $h = \sqrt{l^2 + t^2} - t$. The preceding equation may be thus adapted to the common logarithms,

$$\frac{c}{l} \times 4342945 = \tan. \theta \text{ com. log. cot. } \frac{\theta}{2}$$

But in practice it would be sufficient to hang up a thin metal chain against two points in a vertical board, in such manner that CD and CAD should represent the lengths required on any convenient scale. Then AN and AP should be measured for several different points, and

$$\frac{(AP)^2 - (AN)^2}{(2AN)} \text{ should be found for each.}$$

If the catenary were perfect, these should all give the same result, namely, the required value of t ; but as this will not be found to be the case, a mean of the values should be taken.

When AB is small compared with CD , λ must be nearly a right angle, and t is very great. The catenary in that case is very nearly a part of a parabola, which it was supposed to be altogether by Galileo. The focal distance of that parabola is the half of t . We have seen people puzzled to know how a horse on a towing-path draws a heavy boat by a rope which appears slack, and even dips into the water. The reason is, that the tension necessary to pull a long rope into anything like a straight line, is much greater than that which is necessary to move the boat. A full geometrical account of the catenary, with tables, is given in Ware's 'Tracts on Vaults and Bridges.'

CATGUT STRINGS. Several useful articles, manufactured from the intestines of the sheep, are, for some unexplained reason, denominated catgut. The catgut is generally in the form of cord, string, or twine. The chief purposes to which such cord is applied, are musical strings for harps, violins, and guitars; hatters' bowstrings, for the bowing or disentangling of fur and wool; clockmakers' cord; and thongs or cords for whips—for all of which purposes the material requires a careful preparation before being brought into the state of cord.

The intestines, when taken from the animal, are, by repeated washing and scraping, freed from the loose adherent matters; and are further steeped for some time, as a means of loosening the surface membranes. When this steeping has brought them to a particular state or stage, they are laid on a sloping board, and scraped with the back of a knife, in such a manner as to peel off two strips of peritoneal or external membrane, each equal in width to half the circumference of the intestine. The membrane so removed is called by the French *filandre*, and

is employed by them, when further prepared, for making the cords for rackets and battledores, and also as thread for sewing pieces of intestine together for other purposes. When the membrane is removed, the intestine is again steeped in water, and the inner or mucous membrane scraped from it; and it is also exposed to the action of an alkaline ley, until at length it is brought to as clean a state as possible. The large ends are cut off and applied to other purposes; the smaller ends are laid by for making cord.

In the making of violin-strings, after a process of cleaning, the intestines have a certain degree of twist imparted to them. Two or more are affixed, at the ends, to a rotating machine, and twisted round each other somewhat in the same way as twine or silk. The size of the membranes, and the number of them twisted together, depend on the thickness of the string to be made. The twisted strings are exposed to the action of sulphur in a closed chamber, and are then rubbed with a horsehair cloth; these processes are repeated two or three times. If a string be sulphured too much, it becomes too brittle; if too little, it rarely keeps in tune; the determination of the proper degree of sulphuring becomes therefore a nice point in the manufacture.

The Italians have generally the reputation of making better violin-strings than any other people. The violinists of England, France, and Germany acknowledge the fact, but without being able to assign a sufficient reason for it. The late Dr. Ure suggested the following considerations: It is well known to physiologists that the membranes of lean animals are far more tough than of those animals which are fat or in high condition. In London, where the sheep slaughtered are mostly fat and high-conditioned, the membranes of the animal are supposed to be less tough and tenacious than those of Italy, which are not so highly fed; hence it is inferred that the membrane employed by the Italians is better fitted for the manufacture than that used by the English manufacturers. Whether this be so or not, the fact of the pre-eminence is admitted. Otto, in his 'Treatise on the Violin,' (translated from the German by Mr. Fardely), says in relation to violin strings: "The best strings which have come under my observation are those from Milan, which are sold under the name of Roman strings; they are now to be had at almost every music shop. I shall point out the signs by which the best strings may be distinguished; as there are some imitations of them manufactured at Neukirch, in Voigtland, in Bohemia, and in the Tyrol, which are sold for Italian. The Milanese strings are as clear and transparent as glass. The third string should be equally clear as the first. They must by no means feel smooth to the touch, for they are not ground or polished off by any process, as all other manufactured strings are. If a good string be held by one end in the finger, and opened out, it will recoil to its former position like a watch spring. Every string, when stretched on the instrument, should look like a thin strip of glass on the finger-board: those which are of a dull and opaque appearance are useless. The Milanese strings are also distinguished by each separate one being tied twice with red silk; which however the Neukirch string-makers have imitated. Their elasticity is after all the best criterion; as no other strings which I have tried have that strength and elasticity for which the Milanese are so much esteemed."

The thickest string of the violin, and many other musical strings, are coated with an envelope of fine wire. This is done by stretching the string very tightly, applying the wire at one end of it, and causing the wire to coil helically round the string by giving it a rotatory motion.

For the strong thick cord used for hatters' bowstrings, the largest of the membranes are used, after being cleansed and prepared; from four to twelve of them being twisted together, according to the size of the cord to be produced. The pieces are twisted to a length of fifteen, twenty, or twenty-five feet; and to effect this, pieces of the membrane are sewed end to end, till they produce the required length. While under the process of twisting, the cord is well rubbed between the fingers, to equalise the thickness. The cord is exposed twice to the fumes of sulphur, and is rubbed repeatedly afterwards.

The catgut employed by clockmakers is prepared from the smaller intestines, well prepared with potash. The hollow membranous tube is sometimes cut into two strips in a curious way. The tube is drawn over a ball, behind which is a kind of knife having two cutting edges or blades, whereby the tube is ripped up into two oblong strips of equal width. The method somewhat resembles that by which straws are split for the straw-plait manufacture. For larger and stronger purposes, clockmakers sometimes use cord composed of two or more intestines twisted together, as for violin-strings. The catgut for whips and similar purposes is prepared and wrought much in the same way; short pieces being sewed together to produce a piece of the requisite length, and this being twisted to give it a sufficient degree of strength. The bands or cords for turning-lathes used generally to be formed of coarse horse-gut; but these are now mostly superseded by India-rubber bands.

For the mode of preparing, from a membrane covering the intestine of the ox, the fine pellicle known by the name of "gold-beaters' skin," see GOLD-BEATING.

CATHARTICS are material agents which cause a transient but special irritation of the intestinal canal, followed by alvine dejections. It is not necessary that these substances should be placed in direct or immediate contact with the mucous membrane of the intestines, either

at its upper extremity (the mouth) or at its lower extremity (the rectum); many of them, when applied to the skin, or injected into a vein, will produce the same effect. This irritation is felt at first merely by the mucous membrane, but secondarily it excites the muscular coat so as to increase the peristaltic and vermicular motions of the intestines. The irritation differs in kind and degree. When it affects the membrane merely so far as to occasion a gentle local action, and is followed only by the expulsion of the matter then resting upon or covering it, without augmenting the quantity or altering the nature of this matter, the agents which produce such effect are termed *laxatives*. But if the action be more considerable, and not only the present contents be expelled by their effect, but also the quantity of the secretions of the canal be increased, and their quality perhaps greatly altered, they are termed *purgatives*: and, according to the particular secretion which they most obviously augment, they receive their appropriate name—chologogues, if it be the bile: hydrogogues, if merely the serous fluid. Their effects also frequently extend to the whole system. If their action be very violent, they are designated *drastic purgatives*.

To comprehend fully the manner in which cathartics act, it is necessary to direct our attention to the structure and functions of the intestinal canal. This canal extends from the mouth to the rectum, comprising the organs of taste and mastication, of insalivation, the stomach, and the small and large intestines. It is lined with a mucous membrane, the folds or plaits of which increase its surface, while the follicular glands which it possesses pour out a viscid mucus, a quantity of which is essential to the due execution of its office: this quantity is often much increased by certain purgatives, as we see by the glairy mucous stools. Independently of the juices poured from the glands and vessels into the stomach, the duodenum, or upper small intestine, receives the extremity and contents of the gall-duct and that of the pancreas. Many purgatives in their passage stimulate these ducts, and excite the glands connected with them to increased action. Beneath the mucous membrane is the muscular coat, the chief agent in effecting the propulsion of the contents of the canal. It consists of two sets of fibres, the one arranged in a longitudinal direction, the other in a circular manner. The regular and progressive contraction of these is necessary to move the contents of the canal onwards along its course. The contraction of the one resembling the contractions of a worm in its progress, is termed *vermicular*, and the other *peristaltic*. When their contractions do not harmonise, colicky pains are felt, and are of frequent occurrence during the operation of purgatives, many of which powerfully stimulate this coat to action. When the muscular coat has its action inverted, and the contractions take place from below upwards, instead of from above downwards, it is termed the *anti-peristaltic* motion, by which the contents of the intestines are often ejected by the mouth, as happens in ileus and some other diseases. The last coat or serous membrane, called also peritoneal coat, only obeys the laws of the preceding two in respect to its motion or quiescence. In addition to these structures, the intestines receive numerous arteries, and when an irritant affects them, the blood flows thither in increased quantity. The contact of a purgative causes the capillaries to enlarge: the inner surface of the intestines becomes redder, swollen, and warmer—a state generally followed by a large increase of the serous exhalation from the extremities of these vessels. Lastly, the nerves of the intestines are mostly derived from ganglions of the great sympathetic, by which an important connexion and sympathy is kept up between the intestines, the brain, and spinal chord.

All parts of the intestines do not feel in an equal degree the effect of a cathartic irritant. Some purgatives act more on one part than another, but it may be stated generally that the duodenum, the colon, and the rectum are most under the influence of them. Cathartics also differ essentially in their mode of action, as well as in general in dose, according as they are derived from the mineral or vegetable kingdom. All those from the mineral kingdom, with the exception of calomel, are neutral salts, and are in their secondary effect pre-eminently antiphlogistic, while their dose is considerable. Owing to their solubility they are frequently given dissolved in water, which influences their action. Those from the vegetable kingdom have nearly all a more or less foetid odour, which often causes the stomach to revolt, and occasions nausea. Their impression upon the organs of taste is often bitter and very disagreeable. They generally contain a large proportion of bitter and extractive matters, resins, and gum-resins. Their dose is often very small, from a quarter or half a grain to a very few grains: hence they are often administered in the form of pill, bolus, powder, or electuary, more rarely dissolved in water, sometimes in wine or alcohol, or in the form of extract simple or alcoholic. Several of those from the vegetable kingdom may be applied to the skin, and will produce the usual effect either by rubbing in, as with castor-oil, or spread on the face of a poultice and applied over the abdomen for a short time. Scarcely any articles from the animal kingdom are used as purgatives, though ox-gall and the roe of certain fishes are deemed laxative. Many fruits, both in their fresh state or preserved, such as prunes, are mildly cathartic. The sudden application of cold to the surface of the body frequently has a useful cathartic action.

By the combination of many purgative substances in the same prescription, their effect is rendered more certain, and at the same time

milder. It is also frequently very advantageous to combine purgatives with emetics, or with tonics.

With respect to the practical employment of purgatives, general rules only can be given here. There is scarcely any disease in which they have not been employed, or at least recommended; but as much injury may result from their injudicious or unnecessary employment, as good from their careful selection and proper application. The circumstances which call for their use are either where an individual, enjoying otherwise sound health, has not that regular action of the bowels which is at once needful for his present comfort and desirable as a safeguard against disease; or else when the system is labouring under some other malady, the symptoms of which are aggravated by the retention in the bowels of their contents, which, under such circumstances, are very apt to be of an unhealthy kind. But as these states may occur in individuals of every constitution, and may be accompanied, in the latter case, with many other symptoms which require to be taken into consideration, it is obvious that it is not enough that some purgative medicine be administered: an appropriate selection is necessary. Hence in the course of the same disease (for example, during continued fever), though purgative medicines may be necessary through its whole course, very different medicines must be employed towards the latter stage from those at the beginning. No person unacquainted with medicine would think of treating a case of severe fever, where professional assistance could be obtained, but yet in other diseases, or even where there is no disease, unprofessional persons undertake to decide for themselves or others when a purgative medicine is necessary, and what it should be. The late Dr. Reid stated it as his conviction derived from extensive observation at a dispensary, that one half the children that died in London under two years of age were killed by mothers and nurses dosing them with rhubarb and magnesia. For very delicate children nothing can be worse than the frequent use of magnesia. Even grown up persons may be injured by it, either by its debilitating action, or by its accumulating in the intestines: a mass weighing six pounds has been found in the intestines of a person who had frequently used it. Drastic purgatives, especially of a resinous kind, such as scammony or camboge, when frequently repeated, deprive the inner coat of the intestines of its covering of mucus, and excite inflammation, which often terminates fatally. Excessive purging also may result from an over-dose, and plunge the person into such a state of debility as to place him in imminent danger, or even cause death, either immediately or remotely.

Habitual constipation certainly requires to be remedied, but this is best done by mild laxatives, diet, and proper exercise. When the fault is in the rectum merely, enemata of warm water or gruel may be used, for a few times at first, to remove and prevent accumulations in this part of the bowel. But even these apparently simple means should not be had recourse to without medical advice, as the nature of the constitution of the individual must be taken into consideration, and certain precautions observed. It is frequently serviceable to confine persons of a scrofulous habit to the house during the use of purgatives, as they are peculiarly liable to be affected by cold before their operation has passed off. A layer or roller of flannel over the bowels is beneficial in such persons, especially in winter, during the operation of purgatives. A similar belt is useful in *spontaneous diarrhoea*, especially if cholera, either English or Asiatic, be prevalent. The opposite state to constipation, diarrhoea or looseness, is often best treated by purgatives, especially if it arise from the presence of any undigested food, or unhealthy secretions in the intestines. The mucous fever and diarrhoea of children yields to purgatives sooner than to any other means. The same may be said of many spasmodic diseases, especially in children and females; but as in the treatment of these complaints medical superintendence cannot be dispensed with, we deem further remarks unnecessary. (Hamilton 'on Purgative Medicines,' 8th edit.)

CATHARTIN, the active principle of the various species of *Cassia*, which are used under the name of Senna.

CATHEDRAL. Certain churches are called cathedrals or cathedral churches. They are so called in consequence of having a seat of dignity (*cathedra*, a Greek term for such a seat) appropriated to a bishop or archbishop. Thus there is the cathedral church of Canterbury, the cathedral church of Norwich, the cathedral church of Wells. [CHURCH.] They have usually also a dean and body of canons or prebendaries: but this is not essential to constitute a cathedral church, nor is every church that has a chapter of canons a cathedral church. [BISHOP; CANON.]

CATHETOMETER (from *κάθετος*, a vertical line, and *μέτρον*, a measure), is an instrument for measuring the difference in level (that is, the vertical difference in height) between two liquid columns in equilibrium. It was devised by Dulong and Petit in the course of their researches on the dilatation of liquids by heat, and has been improved in form by Pouillet, who also gave it the name of *cathetometer*. [HEAT.] Regnault has made great use of it in his researches; and, as M. Jamin observes in his 'Cours de Physique,' "there is no more convenient piece of apparatus, when it is well managed; none more fallacious, when badly regulated." In its simplest form, it consists merely of a telescope sliding vertically on an upright scale, the motion of which between the two levels shows the difference of their heights. An example of its application will be seen under BAROMETER.

We will now describe briefly the cathetometer, in the form used by M. Pouillet. The instrument is supported upon a base, which is placed and kept level by means of three screws. From this base rises a rigid vertical axis, to which is fitted a case (a) turning freely round it; and to the case is fixed a divided scale (bb') moving along with it. The scale is further fixed, so as to be inflexible, by means of the rod (c), while a horizontal telescope (d), with its level (e), moves up and down throughout the whole length bb', and the support of the telescope is fitted with a vernier. The telescope has in its interior a pair of spider-threads, crossed at right angles, so that when the image of a point is seen to coincide with the point where the threads cross, we are sure that this point is on the optic axis of the instrument.

In order to set and test the cathetometer, the telescope is placed horizontally at first by means of its level, and the screws in the base are then turned until the level remains perfectly at rest during an entire revolution of the scale round the axis of rotation.

Suppose, then, that we have to measure the difference in height between two liquid columns, which communicate, as in Dulong's experiment, by a horizontal tube. While the liquid is of the same temperature throughout, the level will be, of course, the same in both. This being the case, place the telescope of the cathetometer so that, on turning it round horizontally, both levels will appear successively at the crossing of the spiders' threads, while some other mark, previously fixed, shall appear at the same place. Then, on surrounding one of the columns with melting ice, and the other with hot water, one level will fall and the other rise; and we have only to raise the telescope a certain distance above the fixed point to know how much the one has dilated, and to depress it so much below that point to find the contraction of the other;

whence the absolute dilatation of the liquid may be easily found.

CATHOLIC CHURCH (Roman).* Although in ordinary language this name is often used to designate the ruling authority or power in the Catholic religion, as if distinct from the members of that communion, yet the definition which Catholics give of the Church is such as to comprehend the entire body of its members as well as its rulers, the flock as much as the shepherds. Thus we hear of Catholics being under the dominion of their Church, or obliged to obey it, as though it were something distinct from themselves, or as if they were not a part of their Church. This preliminary remark is made to explain a certain vagueness of expression, which often leads to misapprehension, and serves as the basis of incorrect ideas regarding the peculiar doctrines of that Church—a vagueness similar to what is frequent in writing and speaking on jurisprudence; as, for example, where the government of a country is considered as a power distinct and almost at variance with the nation which it rules, and not an integral part thereof.

The Catholic Church therefore is defined to be the community of the faithful united to their lawful pastors, in communion with the see of Rome or with the pope, the successor of St. Peter and vicar of Christ on earth.

Simply developing the terms of this definition, we will give a brief sketch of the constitution or fundamental system of this Church, under the heads of its government, its laws, and its vital or constitutive principle.

I. The government of the Catholic Church may be considered

* It may prevent a possible misconception to note here that the plan adopted in the 'Penny Cyclopædia,' and adhered to in the present work, in reference to articles intended to give an account of the doctrines held by particular Churches and communities, was, whenever practicable, to obtain an authentic statement of those doctrines from some person of acknowledged position in the body itself, and to confine the article strictly to such a statement. Thus the article Catholic Church was written by a Catholic clergyman of eminent learning and ability, who has since been elevated to a high dignity in that Church: and it is here reprinted exactly as it originally appeared, as far as regards the principles, and with only the corrections rendered necessary in the historical portion by the events that have occurred since the original was written.

monarchical, inasmuch as the pope is held in it to be the ruler over the entire Church, and the most distant bishop of the Catholic Church holds his appointment from him, and receives from him his authority. No bishop can be considered lawfully consecrated without his approbation. The dignity or office of pope is inherent in the occupant of the see of Rome, because the supremacy over the Church is believed to be held in virtue of a commission given to St. Peter, not as his own personal prerogative, but as a part of the constitution of the Church, for its advantage, and therefore intended to descend to his successors, as the episcopal power did from the apostles to those who succeeded them in their respective sees.

The election of the pope, therefore, devolves upon the clergy of Rome, as being their bishop; and it is confided to the college of cardinals, who, bearing the titles of the eldest churches in that city, represent its clergy, and form their chapter or electoral body. The meeting or chapter formed for this purpose alone is called a *conclave*. The cardinals are in their turn appointed by the pope, and compose the executive council of the Church. They preside over the various departments of ecclesiastical government, and are divided into boards or congregations, as they are called, for the transaction of business from all parts of the world; but every decision is subject to the pope's revision, and has no value except from his approbation.

On some occasions they are all summoned together to meet the pope on affairs of higher importance, as for the nomination of bishops, or the admission of new members into their body; and then the assembly is called a *consistory*. The full number of cardinals is 72, but there are always some hats left vacant.

The Catholic Church being essentially episcopal is governed by bishops, who are of two sorts, bishops in ordinary, and vicars apostolic. By the first are meant titular bishops, or such as bear the name of the see over which they rule, as the Archbishop of Paris, or of Tuam, the Bishop of Cambray, or New Orleans. The manner of appointing such bishops varies considerably. Where they are unshackled by the government, the clergy of the diocese meet in chapter, according to old forms, and having selected three names, forward them to the Holy See, where one is chosen for promotion. This is the case in England, Ireland, Belgium, and perhaps in the free states of America. In most countries, however, the election of bishops is regulated by *concordat*; that is, a special agreement between the pope and the civil government. The presentation is generally vested in the crown; but the appointment must necessarily emanate from the pope.

The powers of bishops, and the manner of exercising their authority, are regulated by the canon law; their jurisdiction on every point is clear and definite, and leaves no room for arbitrary enactments or oppressive measures. Yet it is of such a character as, generally considered, can perfectly control the inferior orders of clergy, and secure them to the discharge of their duty. In most Catholic countries there is a certain degree of civil jurisdiction allowed to the bishops, with judicial powers, in matters of a mixed character, as in cases appertaining to marriages, where a distinction between civil and ecclesiastical marriage has not been drawn by the legislature. Some offences connected with religion, as blasphemy or domestic immorality, are likewise brought under their cognisance.

In some places, chiefly those which are dependencies of England, as in Gibraltar, the Cape of Good Hope, and the East Indies, the bishops who superintend the Catholic Church and represent the papal authority, are known by the name of *vicars apostolic*; thus at Calcutta, the vicar apostolic of West Bengal is archbishop in partibus of Edessa. A vicar apostolic is however not necessarily a bishop. Generally, however, he receives episcopal consecration; and, as from local circumstances, it is not thought expedient that he should bear the title of the see which he administers, he is appointed with the title of an ancient bishopric now in the hands of infidels, and thus is called a bishop *in partibus infidelium*, though the last word is often omitted in ordinary language. A vicar apostolic, being generally situated where the provisions of the canon law cannot be fully observed, is guided by particular instructions, by precedents and consuetude, to all which the uniformity of discipline through the Catholic Church gives stability and security. The powers of a vicar apostolic are necessarily more extended than those of ordinary bishops, and are ampler in proportion to the difficulty of keeping up a close communication with Rome. Thus many cases of dispensation in marriage which a continental bishop must send to the Holy See may be provided for by a vicar apostolic; and other similar matters, for which these must consult it, could at once be granted by the ecclesiastical superiors of the Mauritius or of China. The nomination of vicars apostolic is solely with the pope. In America, in England, and some other places, the vicars apostolic have been replaced by bishops bearing the title of some town within their diocese.

The inferior clergy, considered in reference to the government of the Church, consists mainly of the parochial clergy, or those who supply their place. In all countries possessing a hierarchy, the country is divided into parishes, each provided with a *parochus* or *curate*, corresponding to the rector or vicar of the English Established Church; the curate in the English and Irish churches being only equivalent to the *vicare* of France and the *sotto curato* of Italy. The appointment to a parish is vested in the bishop, who has no power to remove again at will, or for any cause except a canonical offence juridically proved. The right of presentation by lay patrons is, however, in particular

instances fully respected. In Italy the parish priests are generally chosen by competition; as upon a vacancy, a day is appointed on which the testimonials of the different candidates are compared, and they themselves personally examined before the bishop in theology, the exposition of scripture, and extemporaneous preaching; and whoever is pronounced, by ballot, superior to the rest, is chosen.

Under an apostolic vicariate, the clergy corresponding to the parochial clergy generally bear the title of *apostolic missionaries*, and have *missions* or local districts with variable limits placed under their care; but are dependent upon the will of their ecclesiastical superiors.

Besides the parochial clergy, there is a considerable body of ecclesiastics, who do not enter directly into the governing part of the Church, although they help to discharge some of its most important functions. A great number of *secular* clergy are devoted to the conduct of education, either in universities or seminaries; many occupy themselves exclusively with the pulpit, others with instructing the poor, or attending charitable institutions. A certain number also fill prebends, or attend to the daily service of cathedrals, &c.; for in the Catholic Church, pluralities, where the cure of souls exists, are strictly prohibited, and consequently a distinct body of clergy from those engaged in parochial duties, or holding rectories, &c., is necessary for those duties. Besides this auxiliary force, the *regular* clergy, or monastic orders, take upon them many of these functions. These institutions, however closely connected with the Church, may require a fuller explanation in their proper place. The clergy of the Catholic Church in the West are bound by a vow of celibacy, not formally made, but implied in their ordination as *sub-deacons*. This obligation of celibacy is only reckoned among the disciplinary enactments of the Church. The clergy of that portion of the Greek and Armenian Church which is united in communion with the see of Rome, may be married; that is, may receive orders if married, but are not allowed to marry after having taken orders. A similar discipline, if thought expedient by the Church, might be introduced into the West.

The only point concerning the government of the Catholic Church which remains to be mentioned, is the manner in which it is exercised. The most solemn tribunal is a *general council*, that is, an assembly of all the bishops of the Church, who may attend either in person or by deputy, under the presidency of the pope or his legates. When once a decree has passed such an assembly, and received the approbation of the Holy See, there is no further appeal. Distinction must be, however, made between *doctrinal* and *disciplinary* decrees; for example, when in the council of Trent it was decreed to be the doctrine of the Church, that marriage is indissoluble, this decree is considered binding in the belief and on the conduct, nor can its acceptance be refused by any one without his being considered rebellious to the Church. But when it is ordered that marriages must be celebrated only in presence of the parish priest, this is a matter of discipline, not supposed to rest on the revelation of God, but dictated by prudence; and consequently a degree of toleration is allowed regarding the adoption of the resolution in particular dioceses. It is only with regard to such decrees, and more specifically the one we have mentioned, that the council of Trent is said to have been received, or not, in different countries.

When a general council cannot be summoned, or when it is not deemed necessary, the general government of the Church is conducted by the pope, whose decisions in matters of discipline are considered paramount, though particular sees and countries claim certain special privileges and exemptions. In matters of faith it is admitted that if he issue a decree, as it is called, *ex cathedra*, or as head of the Church, and all the bishops accept it, such definition or decree is binding and final. The great difference between the Transalpine and Cisalpine divines, as they are termed, is whether such a decree has its force prior to, or independent of, the accession of the body of bishops to it, or receives its sanction and binding power from their acceptance. Practically there is little or no difference between the two opinions; yet this slight variety forms a principal groundwork of what are called the liberties of the Gallican church.

The discipline or reformation of smaller divisions is performed by provincial or diocesan synods. The first consist of the bishops of a province under their metropolitan; the latter of the parochial and other clergy under the superintendence of the bishop. The forms to be observed in such assemblies, the subjects which may be discussed, and the extent of jurisdiction which may be assumed, are laid down at full in a work of the learned Benedict XIV., entitled '*De Synodo Diocesana*.' The acts and decrees of many such partial synods have been published, and are held in high esteem among Catholics; indeed, they may be recommended as beautiful specimens of deliberative wisdom. Such are the decrees of the various synods held at Milan under the virtuous and amiable St. Charles Borromeo.

II. The *laws* of the Catholic Church may be divided into two classes, those which bind the interior, and those which regulate outward conduct. This distinction, which corresponds to that above made, between doctrinal and disciplinary decrees, may appear unusual, as the term *laws* seems hardly applicable to forms of thought or belief. Still, viewing, as we have done, the Catholic Church under the form of an organised religious society, and considering that it professes to be divinely authorised to exact interior assent to all that it teaches, under the penalty of being separated from its communion, we think we can

well classify under the word *law* those principles and doctrines which it commands and expects all its members to profess.

Catholics often complain that doctrines are laid to their charge which they do not hold, and in their various publications protest against their belief being assumed upon any but authoritative documents: and as such works are perfectly accessible, the complaint must appear reasonable as well as just. There are several works in which an accurate account is given of what Catholics are expected to believe, and which carefully distinguish between those points on which latitude of opinion is allowed, and such as have been fully and decisively decreed by the supreme authority of the Church. Such are Veron's '*Regula Fidei*,' or Rule of Faith, a work lately translated into English, and Holden's '*Analysis Fidei*.' But there are documents of more authority than these; for example, the '*Declaration*' set forth by the vicars apostolic or bishops in England, in 1823, often republished; and still more the '*Catechismus ad Parochos*,' or '*Catechism of the Council of Trent*,' translated into English not many years ago, and published in Dublin. A perusal of such works as these will satisfy those who are desirous of full and accurate information regarding Catholic tenets, of their real nature, and show that the popular expositions of their substance and character are generally incorrect.

The formulary of faith, which persons becoming members of the Catholic Church are expected to recite, and which is sworn to upon taking any degree, or being appointed to a chair in a university, is the creed of Pius IV., of which the following is the substance:—

The preamble runs as follows: "I, N. N., with a firm faith believe and profess all and every one of those things which are contained in that creed, which the holy Roman Church maketh use of." Then follows the Nicene creed.

"I most steadfastly admit and embrace apostolical and ecclesiastical traditions, and all other observances and constitutions of the same Church.

"I also admit the holy scriptures, according to that sense which our holy mother the Church has held and does hold, to which it belongs to judge of the true sense and interpretation of the scriptures: neither will I ever take and interpret them otherwise than according to the unanimous consent of the fathers.

"I also profess that there are truly and properly seven sacraments of the new law, instituted by Jesus Christ our Lord, and necessary for the salvation of mankind, though not all for every one,—to wit: baptism, confirmation, the eucharist, penance,* extreme unction, holy orders,† and matrimony; and that they confer grace; and that of these, baptism, confirmation, and order cannot be reiterated without sacrilege. I also receive and admit the received and approved ceremonies of the Catholic Church, used in the solemn administration of the aforesaid sacraments.

"I embrace and receive all and every one of the things which have been defined and declared in the holy Council of Trent, concerning original sin and justification.

"I profess likewise that in the mass there is offered to God a true, proper, and propitiatory sacrifice for the living and the dead; and that in the most holy sacrament of the eucharist there is truly, really, and substantially, the body and blood, together with the soul and divinity, of our Lord Jesus Christ; and that there is made a change of the whole substance of the bread into the body, and of the whole substance of the wine into the blood, which change the Catholic Church calls *transubstantiation*. I also confess that under either kind alone Christ is received whole and entire, and a true sacrament.

"I firmly hold that there is a *purgatory*, and that the souls therein detained are helped by the suffrages of the faithful.

"Likewise, that the saints reigning with Christ are to be honoured and invoked, and that they offer up prayers to God for us; and that their relics are to be had in veneration.

"I most firmly assert that the images of Christ, of the mother of God, and also of other saints, ought to be had and retained, and that due honour and veneration are to be given them.

"I also affirm that the power of indulgences was left by Christ in the Church, and that the use of them is most wholesome to Christian people.

"I acknowledge the holy Catholic Apostolic Roman Church for the mother and mistress of all churches; and I promise true obedience to the Bishop of Rome, successor to St. Peter, prince of the apostles and vicar of Jesus Christ."

Then follow clauses condemnatory of all contrary doctrines, and expressive of adhesion to all the definitions of the Council of Trent.

It is obvious that this form of confession was framed in accordance to the decrees of that council, and consequently has chiefly in view the opinions of those who followed the Reformation. It would be foreign to our purpose to enter into any explanations of the doctrines here

* Under penance is included confession; as the Catholic sacrament of penance consists of three parts: contrition or sorrow, confession, and satisfaction.

† The clerical orders of the Catholic Church are divided into two classes, *sacred* and *minor* orders. The first consists of subdeacons, deacons, and priests, who are bound to celibacy and the daily recitation of the *Breviary*, or collection of psalms and prayers, occupying a considerable time. The minor orders are four in number, and are preceded by the *tonsure*, an ecclesiastical ceremony in which the hair is shorn, initiatory to the ecclesiastical state.

laid down, much less into any statement of the grounds on which Catholics hold them, as we purposely refrain from all polemical discussion.

Such is the doctrinal code of the Catholic Church; of its moral doctrines we need not say anything, because no authorised document could be well referred to that embodies them all. There are many decrees of popes condemnatory of immoral opinions or propositions, but no positive decrees. Suffice it to say, that the moral law, as taught in the Catholic Church, is mainly the same as other denominations of Christians profess to follow.

Of the disciplinary or governing code we have already spoken, when we observed that it consisted of the Canon Law, which, unlike the doctrinal and moral code, may vary with time, place, and accidental circumstances.

III. Our last head was the essential or constitutive principle of the Catholic Church. By this we mean that principle which gives it individuality, distinguishes it from other religions, pervades all its institutions, and gives the answer to every query regarding the peculiar constitution outward and inward of this Church.

Now, the fundamental position, the constitutive principle, of the Catholic Church, is the doctrine and belief that God has promised, and consequently bestows upon it, a constant and perpetual protection, to the extent of guaranteeing it from destruction, from error, or fatal corruption. This principle once admitted, everything else follows. 1. The infallibility of the Church in its decisions on matters concerning faith. 2. The obligation of submitting to all these decisions, independently of men's own private judgments or opinions. 3. The authority of tradition, or the unalterable character of all the doctrines committed to the Church; and hence the persuasion that those of its dogmas, which to others appear strange and unscriptural, have been in reality handed down, uncorrupted, since the time of the apostles, who received them from Christ's teaching. 4. The necessity of religious unity, by perfect uniformity of belief; and thence as a corollary the sinfulness of wilful separation or schism, and culpable errors or heresy. 5. Government by authority, since they who are aided and supported by such a promise must necessarily be considered appointed to direct others, and are held as the representatives and vicegerents of Christ in the Church. 6. The papal supremacy, whether considered as a necessary provision for the preservation of this essential unity, or as the principal depository of the divine promises. 7. In fine, the authority of councils, the right to enact canons and ceremonies, the duty of repressing all attempts to broach new opinions: in a word, all that system of rule and authoritative teaching which must strike every one as the leading feature in the constitution of the Catholic Church.

The differences, therefore, between this and other religions, however complicated and numerous they may at first sight appear, are thus in truth narrowed to one question; for particular doctrines must share the fate of the dogmas above cited, as forming the constitutive principle of the Catholic religion. This religion claims for itself a complete consistency from its first principle to its last consequence, and to its least institution, and finds fault with others, as though they preserved forms, dignities, and doctrines which must have sprung from a principle by them rejected, but which are useless and mistaken the moment they are disjoined from it. Be this as it may, the constitution of the Catholic Church should seem to possess, what is essential to every moral organised body, a principle of vitality which accounts for all its actions, and determines at once the direction and the intensity of all its functions.

To conclude our account of the Catholic Church, we will give a slight view of the extent of its dominions, by enumerating the countries which profess its doctrines, or which contain considerable communities under its obedience. In Europe, Italy, Spain, Portugal, France, Belgium, the Austrian empire, including Hungary, Bavaria, Poland, and the Rhenish provinces of Prussia, which formerly belonged to the ecclesiastical electorates, profess the Catholic religion as that of the state, or, according to the expression of the French *charte*, that of the majority of the people. In America, all the countries which once formed part of the Spanish dominions, both in the southern and northern portion of the continent, and which are now independent states, profess exclusively the same religion. The empire of Brazil is also Catholic. Lower Canada, and all those islands in the West Indies which belong to Spain or France, including the republic of Haiti, profess the Catholic faith; and there are also considerable Catholic communities in the United States of North America, especially in Maryland and Louisiana. Many Indian tribes, in the Canadas, in the United States, in California, and in South America, have embraced the same faith. In Asia there is hardly any nation professing Christianity which does not contain large communities of Catholic Christians. Thus in Syria the entire nation or tribe of the Maronites, dispersed over Mount Libanus, are subjects of the Roman see, governed by a patriarch and bishops appointed by it. There are also other Syriac Christians under other bishops, united to the same see, who are dispersed all over Palestine and Syria. At Constantinople there is a Catholic Armenian patriarch who governs the united Armenians, as they are called, large communities of whom also exist in Armenia proper. In the Indian peninsula, including Ceylon, the number has been estimated at 600,000; they are governed by thirteen vicars apostolic with episcopal consecration, being all of them bishops *in partibus*.

In China, Tonkin, and Cochin-China, likewise, the professors of the Roman Catholic faith are numerous. In Africa, the islands of Mauritius and Bourbon are Catholic, and all the Portuguese settlements on the coasts, as well as the Azores, Madeira, the Cape Verd, and the Canary Islands.

CATHOLIC EPISTLES is the name given to the Epistles of the Apostles James, Peter, John, and Jude. They are called Catholic,—that is, “universal,” according to the original meaning of the word,—because they are addressed not to any particular Church or nation, like the Epistles of St. Paul, but to the faithful in general then scattered about the world. St. James addresses his Epistle to the twelve tribes that are scattered abroad, meaning the converted Jews in Judæa and other Roman provinces. St. Peter addresses his first Epistle to the strangers scattered throughout Pontus, Galatia, Cappadocia, Asia, and Bithynia. St. John addresses the second of his Epistles to the elect lady and her children, meaning the universal Church and its disciples; and Jude addresses his to the faithful in general.

CATOPTRICS. [OPTICS.]

CATTI, a people of Old Germany, who lived between the Rhine and the Visurgis (Weser), as far east as the borders of the Hercynian forest. Tacitus ('German,' 30) describes them as a fierce, hardy, robust race, skilful in their mode of warfare, which partook more of the character of a regular campaign than of that of the predatory incursions of other German tribes. Unlike other German nations, whose chief strength lay in their cavalry, the Catti fought chiefly on foot. The Batavi were a tribe of the Catti, who left their native grounds on account of some domestic differences, and settled in the islands at the mouth of the Rhine. [BATAVI.] The Catti, with the Cherusci, Tencteri, and others, fought against Drusus, who defeated them; but some years after they defeated Varus and destroyed his legions. In the reign of Tiberius, Germanicus, the son of Drusus, attacked the Catti with a large force, overran the country, and made a great slaughter of them, sparing neither the women nor the old men. (Tacitus, 'Annal,' i. 55.) The Catti, however, continued in arms against the Romans for a long time after, and we find them under Vitellius aiding the revolt of Civilis, the Batavian chief. They afterwards quarrelled with their neighbours, the Hermanduri, by whom they were nearly exterminated. ('Annal,' xiii. 57.)

CATTLE. In its most extensive sense the word cattle denotes all the larger domestic quadrupeds, which are used for draught or food. In the usual acceptance of the word, it is confined to the ox. The rearing and feeding of cattle is a very important branch of agricultural industry. Much of the success of a farmer depends on the judicious management of live stock, without which his land cannot be maintained in a proper state of fertility. The breeding and fattening of cattle are generally distinct occupations. It is of the greatest importance to the breeder, as well as to the grazier, to ascertain the qualities of each different breed of cattle; to determine which is best suited to his purpose, and which will bring him the greatest profit.

The domestic bull and cow are probably of Asiatic origin. In those countries where they are now found in a wild state, they are evidently descended from domestic animals which have been let loose, or have strayed from the habitations of man. The *Urus*, which ranged wild in the Hercynian Forest, and was a dangerous enemy to those who encountered him, appears to have differed little from the common bull. If he was the indigenous wild animal, he was perhaps the original stock, from which our different European varieties sprung, modified by climate and difference of pasture. This, however, is denied by naturalists, who consider him a distinct species. [BISON.] The small Hindoo ox with a hump on the chine, and the African Cape ox, which is used for riding as well as draught, and has no hump, are both more nearly allied to the buffalo. They are very tame, and more intelligent than the generality of our oxen, owing probably to their being more nearly associated with their masters. Of the cattle on the continent of Europe, one of the principal breeds is the Polish or Ukraine. The oxen of this breed are large and strong, and fatten readily in good pastures. Their flesh is succulent and well-tasted; but the cows do not readily allow themselves to be milked, and consequently are not fit for the dairy. The colour is generally a light gray, seldom either black or white. They are docile when worked, but are not considered so hardy and strong as the Hungarian oxen, which resemble them in colour, but are more compact, and have shorter limbs. The horns are large and spreading, which gives them a formidable appearance, and compared with the more improved and carefully bred cattle, they are heavy and coarse. When they are stalled in winter on hay and roots, they bring a considerable profit by fattening very soon. They are driven in herds from the extensive plains in which they are bred, and sold to graziers in the adjoining districts of Germany.

In the plains of Jutland, Holstein, and Schleswig, there is a very fine breed, with small short crooked horns, which appears to be nearly allied to the Friesland and to our own Holderness breed. They are of various colours; but mouse or fawn colour, interspersed with white, are the most common. Red cows of this breed are seldom seen. They are good milkers in moderate pastures, and the oxen fatten readily when grazed or stall-fed at a proper age. They are fine in the horn and bone, and wide in the loins; but they are not considered so hardy

and strong for labour as the preceding breed. If prejudice did not make the breeders select the calves with large bone and coarse features to rear as bulls, in preference to those which resemble the cows, this breed would soon equal our best short-horns. The cows are frequently fattened while still in milk, and are fit for the butcher by the time they are dry; the same system is followed by the great milkmen in the neighbourhood of London, with their large Holderness cows. This breed is much esteemed in all the northern parts of Europe. The Friesland, Oldenburg, Danzig, and Tilsit cattle are mostly varieties of this short-horned breed.

Towards the Alps the cattle have a different character; they are strong and active, and can range wider in search of pasture. The largest and finest breed is the Swiss, especially the Freyburg race, which is found in the rich pastures between the mountains in the neighbourhood of Greyerz (Gruyères), a place well known for its excellent cheese, which is consumed all over Europe. The cows, which are here the principal object of attention, are large and wide in the flanks, and strong in the horn (we should rank them in England among the middle-horns), short and strong in the bone, with a prominence at the root of the tail, which, according to our notions, would be considered a great blemish. They give abundance of rich milk when ranging in their native Alps, or when stalled and fed with clover or lucern in the stables. The oxen work well, but are rather heavy and slow. When fed off they fatten well; and although fat meat is not much prized there, some carcasses may be seen slaughtered in Bern and Freyburg which are equal to those in the best English markets.

There is a smaller, but very active mountain breed of cattle in the Jura, which does well on scanty food. The cows are small and slight, generally of a light red colour. The oxen are very active and strong for their size. They draw invariably by the horns. They are not considered so profitable for stall feeding as the larger, but they are excellent for the small cottagers on the borders of the mountains, and find their sustenance among the woods and rocks, where they climb like goats.

The Norman breed gives the character to all the cattle usually met with in the northern part of France, except near the Rhine. They are mostly of a light red colour, sometimes spotted with white. Their horns are short, and stand well out from the forehead, turning up with a black tip; the legs fine and slender; the hips high, and the thighs thin. The cows are good milkers, and the milk is rich. They are in general extremely lean, which is owing in a great measure to the scanty food they gather by the sides of roads, and along the grass balks which divide the fields. In Normandy itself they have good pastures, and the cattle are larger and look better. The Alderney and Jersey breeds, which from the extreme richness of their milk are much prized in gentlemen's dairies in England, are smaller varieties of the Norman, with shorter horns, more turned in, and a still more deer-like form.

The Italian breeds are not very remarkable, except from the immense length of the horns of some of them. No great pains are taken to improve them, except in some parts of the north of Italy, where the Parmesan cheese is manufactured: there they resemble the Swiss breed, and are probably only varieties of the same stock.

The different British and Irish breeds have been generally distinguished from each other by the length of the horn. The long-horned breed is supposed by many to be indigenous. Others consider the middle-horned as the old breed. The former was chiefly found in a district of Yorkshire called Craven, and was greatly improved by the skill of Robert Bakewell, of Dishley Farm, in Leicestershire, and hence they are called the Dishley breed. The distinguishing character of this breed are long horns growing downwards from the side of the head and ending in straight points parallel to the jaw. In order to give an adequate idea of the qualities of this improved breed, we must consider what breeders and graziers call the fine points of an ox. These are certain forms and appearances, which are either anatomically connected with a perfect conformation of the body, and especially of the organs of respiration and of digestion, or which are so constantly associated with the peculiar qualities of certain breeds, as to be proofs of their purity. Of the first kind are a wide chest, well formed barrel, strong and straight spine, hip bones well separated, and length of quarter, all which can be proved to be essential to the perfect functions of the body. Small and short bones in the legs give firmness without unnecessary weight. A thick skin well covered with hair ensures proper warmth, and its soft loose feel indicates a good coat of cellular substance underneath, which will readily be filled with deposited fat. All these are indispensable points in an ox which is to be profitably fattened, and whatever be the breed, they will always indicate superiority. Other points, such as colour, form of the horns, of the head, and extremities, the setting on of the tail, with other particulars, are only essential in so far as experience has observed them in the best breeds, and as they are indications of pure blood. The eye is of great importance; it should be lively and mild, indicating a healthy circulation, with a gentle and almost indolent temper. An animal that is not easily disturbed will fatten rapidly, while one that is restless and impatient will never acquire flesh. Amongst the ancients, a deep dewlap was considered as a great beauty in an ox. In some of our best breeds there is scarcely any. The rump of the Freyburg cows, as we observed before, rises high towards

the tail; while a straight back from the neck to the tail is indispensable in a well-bred British ox.

Having established a breed which has many superior qualities, attention is paid to maintain its purity; and to those who cannot ascertain the parentage, certain marks are satisfactory proof of purity of blood. The new Leicester long-horn oxen were noted for the smallness of the bone and their aptitude to fatten. Their flesh was fine-grained, the fat being well intermixed in the muscles. At the time when Bakewell died, about 1795, no other breed could be brought into competition with his improved long-horns. But whether his successors have not paid the same attention to keep up the qualities of the breed, or it has degenerated in comparison, they have since lost much of their reputation, and the short-horned breed has now the superiority. Good long-horned cattle are, however, occasionally seen in the midland counties. One defect of the breed was, that the cows gave but little milk, and this may be the reason for now preferring the short-horns. The Teeswater or Holderness breed of cattle was produced by the importation of cows from Holstein or Holland, and careful breeding and crossing. They now much excel the original stock. The principal improver of the Teeswater breed was Mr. Charles Collins. By his care a breed has been produced which is unrivalled for the dairy, and for fattening readily. Almost every good breed now in existence traces its pedigree to his bulls, especially one of the first he used, called *Hubback*. The famous ox exhibited fifty years ago, under the name of the Durham ox, was of this breed. By careful crossing with a Galloway cow, an improved breed was produced, which was in such repute that at a sale of Mr. Collins's stock of short-horns, October 11, 1810, a famous bull, called Comet, sold for 1000 guineas, and 48 lots of bulls, cows and calves realised 7115*l.* 17*s.* Subsequent sales have proved that the estimation in which the breed is held has not fallen since Charles Collins's time. Thus the late Earl of Ducie's herd a few years ago, fetched 9361*l.* 16*s.* for 62 head, or 150*l.* 19*s.* a piece; and though so large a price cannot be quoted in any other case, yet every year there are sales at which bull and heifer calves fetch upwards of 100*l.* The short-horn cattle are mostly light coloured, some quite white, but most are speckled with red and white, without any large distinct spots. The horns are very short. In the cow, the points turn inwards towards each other. Some of the finest bulls have merely a tip of a horn standing out from each side of the forehead. In the carcass they have every point which we have before enumerated as essential to perfection.

Besides the two breeds above mentioned, there are several in great repute in particular districts, which almost dispute the superiority with the short-horns. Of these the Devonshire breed is the handsomest. The colour of this breed is invariably red, with a very fine head, small bone, and glossy hide. The oxen, although not so heavy as some, are the best for the plough on light lands; they walk nearly as fast as horses, and will work almost as well in pairs. The cows are good milkers, any deficiency in quantity being made up by the richness of the cream. The oxen fatten readily, and their flesh is of the best quality.

The Sussex breed is only distinguished from the Devon by being rather stronger, and not so fine in the head and horn.

The Herefordshire breed is larger and heavier than either of the preceding, the horns longer and more turned outwards; the colour is red, but the belly and the face are generally white, and there is often a white stripe along the back. This breed has many excellent qualities, and fattens well; but the cows are of little use for the dairy, from the small quantity of milk they yield. The Herefordshire oxen are best suited to the rich pastures of their native county, where they grow to a great size and increase fast. These are the principal English breeds. Of the Welsh breeds, the Glamorganshire cows are in good repute for the dairy; they are of a dark brown or black colour with a white stripe along the back, long white horns pointing rather forwards and upwards; the tail is set on rather high above the back, which is thought a defect, but in this they are much exceeded by the Freyburg cows mentioned above, which have great merit notwithstanding. The other Welsh breeds are distinguished chiefly by their hardy constitutions, which they owe to their having been bred in mountainous districts. Great droves of them come to all the English fairs; their low price and small expense of keep render them an object worthy the attention of cottagers and small farmers; they are best calculated to run on rough heaths and commons.

The principal indigenous Scotch breeds are the West Highland, the Galloway, the Angus, and the Shetland. There is a doubt whether the Ayrshire should be classed amongst the pure Scotch cattle. Their great resemblance to the short-horn in all but the size leads one to suppose that they are a cross of a smaller breed by a short-horn bull, but they have very good qualities, and are excellent for the dairy or for stalling.

A great many cattle are bred in the various islands which lie on the western coast of Scotland. They are mostly of a small black or dun-coloured breed, called Kyloes. They are very hardy, and when brought into good pasture, fatten rapidly, and produce the finest and best-flavoured beef. They are found in the greatest perfection in the Isle of Skye, and are sent annually in large droves from their native islands, and dispersed through Scotland and England. They are particularly in request in Norfolk, Suffolk, and Essex, where they are wintered on

turnips, and sent to Smithfield in the spring and summer following. If they do not produce so great a weight of beef as many other breeds, they always bring the highest price in the market, and require but a very short time to get fat. The Galloway is a peculiar breed, which has many good qualities; it has no horns; the body is compact, and the legs short; and few breeds can vie with the Galloway oxen and heifers in aptitude to fatten. There is a peculiar roundness in all the parts of the body, which makes the animal look well in flesh, even when he is lean. The skin is loose, and the hair soft and silky to the touch. They are mostly black, but some are of a dun colour, which shows a connection between this breed and the polled Suffolk. It is only the colour which distinguishes them. Many of the Galloway heifers are spayed, and get very fat at an early age. The Galloway cows are not very good milkers, in which respect they differ from the Suffolk, but their milk is very rich.

The *Angus* is also a polled breed, and has been long in repute. It is probably a variety of the Galloway, to which it bears a strong resemblance, than which it is larger and coarser, but it has been found in Angus from time immemorial.

The Shetland cattle are very diminutive and coarsely shaped, but their flesh is reckoned well flavoured. They are seldom driven into England or the South of Scotland, because when fat they attain but a very small weight. The breed is, however, worth the notice of experimental agriculturists.

The Aberdeenshire and Fifeshire breeds are horned, and have been produced by various crosses with short-horns and other English breeds. All the Scotch breeds have been greatly improved by the premiums given by the Highland Society for the encouragement of breeding.

Of Irish cattle, the small Kerry cow seems to be purely native. It is a useful breed for cottagers, requiring but moderate keep and care, and giving a considerable quantity of milk in proportion to the size of the animal and the food it requires.

Irish cattle are becoming rapidly improved by crosses with the short horn breed, of which numerous herds now exist in that country. They have hitherto been more affected by crosses with the improved Leicester long-horns.

These are the principal breeds of cattle in the United Kingdom. By selecting those which are best suited to each situation and pasture, the industrious farmer may add considerably to his profits, and at the same time enrich his land with the manure. In purchasing cattle it is very necessary that the age should be readily ascertained; the surest mode of doing this is by examining the teeth. A calf has usually two front teeth when he is dropped, or they will appear a day or two after his birth; in a fortnight he will have four, in three weeks six, and at the end of a month eight. After this, these milk-teeth, as they are called, gradually wear and fall out, and are replaced by the second and permanent teeth. At two years old, the two middle teeth are replaced; the next year there will be four new teeth in all; at four years there are six permanent teeth, and at five the whole eight are replaced. The milk-teeth do not always fall out, but are sometimes only pushed back by the second set; and in this case they should be removed with an instrument, as they impede mastication and irritate the mouth. The periods of their appearance are, however, affected like other evidences of growth and maturity by the earlier precocity of well-bred stock; and the following table, taken from Professor Simonds (Vol. xv. 'Journal of the English Agricultural Society'), represents the difference in this respect between mongrel and well-bred cattle.

DENTITION OF THE OX.

Table of early Average.				Table of late Average.			
The breed, &c. Favouring Development.				The breed, &c. Retarding Development.			
Years.	Months.			Years.	Months.		
1	9	Two permanent incisors.		2	3	Two permanent incisors.	
2	3	Four	" "	2	9	Four	" "
2	9	Six	" "	3	3	Six	" "
3	3	Eight	" "	3	9	Eight	" "

After six years old the edges of the teeth begin to wear flat, and as they wear off the root of the tooth is pushed up in the socket, and the width of the teeth is diminished, leaving interstices between them; this begins in the middle teeth, and extends gradually to the corners. At ten years old, the four middle teeth are considerably diminished, and the mark worn out of them. After fifteen years of age, few cows can keep themselves in condition by pasturing; but they may continue to give milk, or be fattened by stalling and giving them ground food. Horned cattle have rings at the root of the horns, by which the age may also be known. The first ring appears at three years of age, and a new one is formed between it and the skull every year after. But this mode of ascertaining the age is not so sure as by the teeth, deception being much easier, by filing off the rings.

In order to learn by experience what breed of cattle is most profitable, it is very advantageous to weigh them occasionally, and note their increase. For this purpose several simple and ingenious weighing machines have been invented. Experience has shown the proportion between the saleable quarters and the offal, in different states of fatness; and tables have been constructed by which the net weight is found by mere inspection. Multiplying the live weight by 0.6, gives a near approximation to the neat dead weight in an ox moderately fat and of a good breed. When an ox is fat, his weight may be very

nearly guessed by measuring his girth immediately behind the fore legs, and the length from the tip of the shoulder to the perpendicular line which touches the hinder parts, or to a wall against which the animal is backed. The square of the girth in inches and decimals is multiplied by the length, and the product multiplied by the decimal .238. This gives the weight of the four quarters, in stones of 14 lb. This rule is founded on the supposition, that there is a certain proportion between the net weight of the quarters and that of a cylinder the circumference of which is the girth, and the axis the length taken as above. The proportion has been ascertained by observation and repeated comparison.* The measurement will at all events indicate the proportional increase during the period of fattening.

Cattle are not subject to many diseases, if they have plenty of food and good water, and are kept clean. Air is essential to them, and although cows will give more milk, and oxen will fatten better when kept in warm stalls in winter, they are both less subject to diseases when they are kept in open yards, with merely a shelter from the snow and rain. Epizootic diseases, which sometimes ravage whole districts, are less known in England than in most countries. For the peculiar diseases of cattle see Ox and Cow.

The most economical mode of feeding cattle is evidently by allowing them to seek their food on commons and uncultivated pastures; but it is only in particular situations that it is the most advantageous. Cattle fed on commons add little to the stock of manure, except when they are kept in the yards or stalls in winter: even then their dung is of little value, if they are merely kept alive on straw or coarse hay, as is generally the case where the stock is kept on commons or mountains in summer. When they feed in inclosed and rich pastures, their dung falling in heaps on the grass does more harm than good. The urine fertilises the soil in wet weather when it is diluted; but in dry weather it only burns up the grass. If we calculate what would be the amount of dung collected if the cattle were kept in yards or stables, and fed with food cut for them and brought there, and also the loss of grass by treading on the pastures, we shall have no doubt whether the additional labour of cutting the grass and bringing it home daily is not amply repaid by the saving. But if we also take into the account the variety of artificial grasses, pulse, and roots which may be grown with advantage on land unfit for permanent grass, and the quantity of arable land which may thus be kept in the highest state of cultivation, we shall be convinced that the practice of those countries where the cattle are constantly kept at home is well worthy of imitation. It may be of use to the health of the animals to be allowed to take a few hours' air and exercise in a pasture near the stable; but there is no advantage in their having any grass crop there: on the contrary, the barer of grass the surface is, the better. They will relish their food better when they are taken in after a few hours' fasting. A bite of fresh short grass might, on the contrary, give them a dislike to their staler food. When cut grass is given to cattle in the stalls, it is best to let it lie in a heap for at least twelve hours before it is given to them. It heats slightly, and the peculiar odour of some of the plants, which oxen and cows are not fond of, being mixed with that of the more fragrant, the whole is eaten without waste. Experience has shown that many plants which cattle refuse in the field, where they have a choice, have nutritious qualities when eaten mixed with others in the form of hay. There are few deleterious plants in good grass land or water meadows, and these are readily distinguished and weeded out. The quantity and quality of the dung of cattle stalled and well fed is so remarkable, that its value makes a considerable deduction from that of the food given; especially of green food, such as clover, lucern, tares, and every kind of leguminous plant. This supposes a sufficient quantity of straw for litter, and an economical collection of the liquid parts in proper reservoirs or tanks. In order to make the feeding of cattle advantageous, the buildings must be conveniently placed with respect to the fields from which the food is to be brought. Moveable sheds, with temporary yards, which can be erected in different parts of a large farm, according as different fields are in grass or roots, are a great saving of carriage, both in bringing the food to the cattle and carrying the dung on the land. A clay bottom should be selected, in a dry and rather high spot, if possible. But if permanent buildings for cattle, constructed of rough materials and thatched with straw, were erected in the centre of about forty acres of arable land, in different parts of a large farm, it would probably be a great saving in the end.

Good water is most essential to the health of cattle, and that which has been some time exposed to the air seems the best for them. When they are fatted in stalls on dry food, they should always have a trough of water within reach. A piece of rock-salt to lick, or some salt given with their food, is highly conducive to their health, and will restore their appetite when it begins to flag. Rubbing the hide with a wisp of straw or a strong brush, as is done to horses, may appear a useless labour, but it is well known that there is no better

* If g be the girth and l the length taken as above, a the area of a circle whose circumference is unity, then $l g^2 a = \text{cylinder}$; and if the proportion of this cylinder has been found by repeated trials to be the weight of the carcass in stones of 14 lb. as $b : 1$, then $l g^2 \times \frac{a}{b}$ is the net weight. In this case $\frac{a}{b}$ has been found = 0.238. $\therefore l g^2 \times 0.238$ is the weight.

substitute for that exercise which is essential to health. Where labour is not regarded, as is always the case when the owner of the cattle attends upon them himself, the curry-comb and the brush are in regular use, and the advantage is not denied.

In those countries where the farmer is allowed to distil a spirit from his grain, it is a great advantage to an agricultural establishment to have a distillery attached to it, especially in a remote situation: and not only is the fattening of cattle on the refuse of the distillation a source of profit, but the manure extends fertility around. The produce in spirits and in cattle is easily transported to a great distance, and almost the whole of what is produced by the land returns to it in the shape of manure. The same may be said of the manufactory of sugar and spirit from beet-root, which has been lately so much extended in the north of France.

It can never be too much impressed upon the minds of agriculturists, that without dung there is no corn; without cattle there is no dung. Every means should therefore be used to encourage the breeding and feeding of cattle, and none can be more effectual than to show that the profits of a farm are always proportioned to the quantity of cattle kept, and the abundance of the food provided for them.

CAUSATION, CAUSE. The word *cause*, in Latin, had more nearly the sense of the Italian *cosa*, *thing*, than that which it now has in English. In the logic of the middle ages it was used in four senses, and these senses show that *causa* was not one limited word, though some sort of notion of *producing* runs through them all. There was the *material* cause, the very substance of the thing produced, certainly a *sine quâ non*: the *formal* cause, the particular arrangement under which the thing is what it is, and not another variation of the same matter: the *efficient* cause, the word *cause* in our English sense: and the *final* cause, the end or object of the existence of the thing. We still draw the distinction between efficient and final cause: but many readers hardly understand this definition; they may carry it with them in one sentence: the existence of disease is the efficient cause of the College of Physicians, the cure which is desired is the final cause.

The subject of causation is one of the darkest in metaphysics. Causation signifies etymologically the *action* of a cause in producing an effect. "The theory of causation ('Essai sur la Psychologie,' Paris, 1826) necessarily supposes three indispensable conditions: 1st. Two objects (agent and patient); 2ndly. Three changes (that of the agent; reason of the effect—that of the patient; effect of the action—that which the patient produces on the agent; effect of reaction); 3rdly. Four distinct moments (that which precedes the action—that in which the action begins—that of the reaction—and that after the reaction.)" The subject of causation has always been one on which the most subtle thinkers have exerted their powers of analysis; but, as in every similar research after final principles which cannot by any effort of the understanding be clearly discerned and defined, opinions remain still as conflicting as when the inquiry first began. The student, in wandering through the mazes of metaphysical dogmatism, is disposed to turn from a subject on which so much has been said and so little determined: he finds that the statements of writers consist either of that which every one already knows, or of that which no one can at all understand. It appears to be agreed that, though in every instance we actually *perceive* nothing more than that the event, change, or phenomenon B always follows the event, change, or phenomenon A, yet that we *naturally believe* in the existence of some unknown *quality* or *circumstance* belonging to the antecedent A, in virtue of which the consequent B always has been, is, and will be produced. The fact of magnetic attraction is usually adduced in illustration of causative influence; and the inquiry, *why* does the magnet move the iron? suggests the idea of that quality which is denoted by the word *power*; about the nature of which metaphysicians have always disagreed, and their dispute remains still unsettled. It is this attributed *efficiency* in the uniform antecedent of a change which philosophers have considered as forming the *relation of cause and effect*; and their endeavour to express the conception of this hypothetical quality has occasioned the employment of a great variety of terms, as energy, faculty, influence, capacity, ability, virtue, force, possibility, fitness, aptitude, &c. The following citations and references may be serviceable to those who desire to examine the learning of the subject. An account of the ancient division of causes into efficient, material, final, and formal, with all the subtleties of the Peripatetic school, is given in Lord Monboddo's 'Ancient Metaphysics,' 4to. vol. i. pp. 33-311; vol. ii. p. 212; and as a choice specimen of the later scholastic doctrine and categorical arrangement of causes, see 'Methodus cognoscendi Causas,' auctore Thom. Isacio, 12mo., 1650. "*Causæ et effectui respondent potentia et actus—illæ eadem sunt res.*" (Hobbes, 'Opera Philos.' c. ix., 'De Causa et Effectu.') The following discrimination is important: "Potentia agentis et causa efficiens (c. x. 'De Potentia'), idem sunt re, differunt autem consideratione; *causa* enim dicitur respectu effectûs jam producti, *potentia* vero respectu ejusdem effectûs *producendi*; ita ut causa *preteritum*, potentia *futurum* respiciat"—"All conception of future (*Ibid.*, 'Hum. Nat.') is conception of *power* able to produce something—we so far conceive that anything will be hereafter as we know that there is something at present that hath power to produce it; and that anything hath power to produce another thing hereafter, we cannot conceive but by remembrance that it hath produced the like heretofore—power simply is the

excess of the power of one (the agent) above that of another (the patient)." "The idea of *power* (Locke, b. ii., c. 21, 'Of Power') is that of *possibility*, faculty, ability to make any change—all power relates to *action*—power is not the agent, but the *relation* (of an object to its future action)—how mind excites motion by the *power* of thought, and how body communicates motion by the *power* of impulse, we are equally in the dark (c. xxiii.)—to have the idea of cause and effect it suffices to consider any thing as beginning to exist by the operation of some other, without knowing the *manner* of that operation (c. xxvi. 'Of Cause and Effect,' and see c. xxv. 'Of Relation')."

The far-famed and much disputed, though not original, opinions of Hume, which, with some slight modification, have been adopted by Dugald Stewart, Dr. Brown, and others, are contained in sec. 4, 5, 6, 7, 8, 11, of his 'Philos. Essays,' from which the following passages are taken. Consistency is not to be looked for in essays professedly *paradoxical*, and designed less for the development of truth than as ingenious specimens of the dialectic art. "We *suppose*," says Hume, "there is a connection between cause and effect; a *power* in the one by which it infallibly *produces* the other—power is that circumstance in the cause by which it is enabled to *produce* the effect—when we consider the *unknown* circumstance of an object by which the degree or quantity of its effect is fixed and determined we call that its *power*—the effect is the measure of the power—the utmost scrutiny can never discover but one event following another, without being able to comprehend any *power* by which the cause operates—no rational philosopher has ever pretended to assign the *ultimate cause* of any natural operation, or to show the action of that *power* which *produces* any effect; these ultimate principles are totally shut up from human inquiry—the *power* of the will in effecting animal motion is unknown and inconceivable; we are ignorant how bodies act on bodies, and how mind acts on itself and on body; it is a thing entirely incomprehensible—we have no idea of power at all: it is a word absolutely without any meaning either in philosophy or common life—were our *ignorance* therefore a good reason for rejecting any thing, we should deny all energy in the Supreme Being as much as in matter; experience only teaches us how one event consequently *follows* another, without instructing us in the secret connection which binds them together; we know nothing more of causation of any kind than merely the constant conjunction of objects: all events seem entirely loose and separate; one follows another, but we never can observe any tie between them: all we know of the matter is, that a cause is that *after* not *by* which anything constantly exists—it is an object *followed* by another, and where all the objects similar to the first are followed by objects similar to the second, or where *if the first had not been the second never had existed*—it is absolutely impracticable to *define* a cause without comprehending as a part of the definition a *necessary connexion* with its effect—belief of similar effects from similar causes is a natural instinct which reasoning can neither produce nor prevent." From observations so full of at least apparent contradiction, it is not surprising that both the denial and admission of the principle of causative power are imputed to their author by different writers. Many of the works written in refutation of Hume contain ingenious remarks, though little of discovery. Beattie 'On Truth,' c. v.; Oswald; Priestley. By Dr. Reid, Hume's opinion of *power* as having no objective reality beyond the imagination, is strongly opposed. ('Intellectual Powers,' 1827, pp. 440-459.) "The notion of power, it is said, is one of our earliest abstractions, a notion the most explicit and universal, for the expression of which all languages have distinct and appropriate words." The remarks of Dr. Price ('Moral Questions,' p. 29) deserve attention: "What can *do nothing*—what is *fitted* to answer no purpose, has no *dependence*, *aptitude*, or *power*—can be nothing real—the whole meaning of *accounting* for a fact implies something in the nature of objects or events that connects them, a *fitness* to influence one another." Price, Reid, Newton, and most writers on the subject, agree that where there is no substance there is no power, that is, that all power is the power of something; but by Sir Wm. Drummond ('Academ. Questions,' 4to, p. 10) and some others, it is contended that "power is not an *attribute*, but an independent primary indemonstrable *principle*, the cause of all things: and that we can possess a notion of the *existence* of it, as of the *vis movendi*, without any notion of its *nature*." The opinions of Dr. Stewart on the subject are not remarkable either for novelty or consistency. ('Elements of Philos.' vols. i. and ii.) "In every change we have an *irresistible* conviction of the operation of some *cause*—it is a law of our nature; the mental association of cause and effect is of a most indissoluble nature—the idea of *cause* or *power* necessarily accompanies the perception of change—the human mind surely has a natural bias to conceive things as somehow linked together; possessed of *powers* and *virtues* which *fit* them to produce particular effects: but that we have no reason to believe this, is evident on a moment's reflection—it is a prejudice." Along with this declaration is enforced the propriety of distinguishing physical from *final* or *efficient* causes, that is from those "powers and virtues" which are declared to have no existence. "There may be," says Dr. Stewart, "no *necessary* connection among any phenomena we observe; the doctrine of necessity depends upon the truth of the proposition that every change has a cause with which it is *necessarily* connected." But what is meant by necessary unless that which cannot be varied or avoided? And surely this may be predicated of human actions, if the laws of matter and mind are immu-

table, that is, if the course of nature does not change, but continues to proceed in its established order; for then, as the universe exhibits an uniformity of sequence in successive phenomena, or, in other words, consists of a series of uniform causes and effects, or *antecedents* and *consequents*, for the difference of name is quite unimportant, man *must*, in the nature of things, assuredly be the creature of circumstances, and *must* act as he is acted on.

The work of Dr. Thos. Brown, entitled 'An Enquiry into the Relation of Cause and Effect,' is well known as a specimen of superior metaphysical analysis. The main points of the theory it contains are given more concisely in one of Dr. B.'s Lectures, vol. i. p. 135, and a particular account of the work, with a notice of some objections to its doctrine, is given by the Rev. David Welsh in his 'Life of Dr. Brown' (p. 98 *et seq.*, and notes I and N in Appendix).

As this 'Enquiry' was originally designed expressly to vindicate and explain the theory of Mr. Hume, it cannot be expected to contain anything essentially or importantly different; and that it does not is evident on a comparison of the leading propositions. Dr. B. perfectly coincides with Hume in maintaining that the relation of cause and effect is not known *a priori*, but from experience; and that after experience it is not discoverable by *reason*, but is merely an object of *belief*—a notion arising from "an instinctive principle of faith." Hume's assertion, that the *sentiment* of this relation is derived from experience only of the *customary* conjunction of objects, and arises merely from the mental act of *transition* from one object to the other, is contradicted by Dr. Brown; but Hume in his paradoxical humour has often incidentally done this for himself. The proposition of Hume that, *as to our knowledge*, there is "nothing but one event or object following another," is that which Dr. B. reiterates throughout the 600 pages of his treatise, in showing that, "in a sequence of causes and effects, whether as to the phenomena of mind or of matter, there is absolutely nothing more than the antecedents and consequents themselves;" that the idea of power, when acutely analysed, is simply the idea of A itself, as that which invariably, and without the intervention of anything whatever, is followed by B: the relation of things as to *power* being, in fact, their relation as to *time*: and the question about cause and effect, a question solely about the uniform priority and posteriority of events in time. The idea of action, force, and energy is also resolved into that of simple antecedent and consequent: so that all is reduced, as Hume has it, to one thing, not *by* but *after* another. This identification of the idea of power with that of an antecedent having an invariable relation to a consequent, only as to *time*, has been regarded by many as virtually a denial of the reality of what is named casual power; but Dr. B., no less than other philosophers, appears to have the same vague conception of an indefinable something which, known only by its operations, constitutes at once a latent portion of the whole qualities of an object, and forms its efficiency to create a certain uniform change in another. He says that power is the relation of a particular antecedent to the uniform change that follows, and that he feels this relation to be a fitness or aptitude in the former to produce the latter. He says that "God formed objects with powers to be antecedents of changes;" that matter, like mind, is capable of beginning changes; and that we believe in the relation of cause and effect, "not because we can demonstrate it to ourselves or to others, but because it is impossible for us to disbelieve it; the belief being in every instance intuitive." But if proof be wanted that Dr. B. entertained an orthodox notion of power as a productive principle, it is given in the positive assertion of his personal friend and biographer, the Rev. Mr. Welsh (p. 131), who says, that were his theory of causation *really* deficient in this particular, instead of commending he should reject it as "a monstrous heresy." If this be so, it is amusing to see Dr. Brown reprimanding Dr. Reid for dealing in "a tissue of distinctions merely verbal," about "a mysterious unintelligible something." The truth is, that *power* is merely a name for human ignorance: the mind feels uneasy and dissatisfied in contemplating the unaccountable gap between an antecedent and consequent, and readily adopts any hypothesis that will put a bridge over it; hence the *power* of gravitation, the *power* of volition, &c. Dr. Brown's definition of cause as that which *immediately* as well as invariably precedes a change involves an obvious *petitio principii*: for the question is whether B really is immediate to A, as known to us? whether there exists a third co-efficient to causation? but this question can never be answered.

Of the numerous strictures which have appeared on the theory of Dr. Brown, we may notice the two following: 'An Essay upon the Relation of Cause and Effect, controverting the doctrine of Hume, Brown, and Lawrence,' 8vo, 1824. The author contends that antecedency and subsequence are not essential to the proper definition of cause and effect; because, although an object, in order to act as a cause, must exist antecedently to such action, yet that when it does act as a cause, its effects are synchronous with that action, and are included in it; that it is not mere sentiment, but reason (the faculty of perceiving the *ratios* of things), which produces the conviction that everything which begins to exist must have a cause; and which forces the mind to perceive that similar causes must necessarily have similar effects, that nature cannot, without a contradiction of terms, be conceived to alter her course, and therefore that no other change could ensue than that which, in any given instance, does ensue; and that we derive, from the observation of changes, and from the operation of

reason, the notion of that producing principle which we denominate *power*. In the translation, by Mr. Henry, of the 'Elements of Psychology,' by Victor Cousin, 1834, the theory of Hume and Brown is considered as asserting an unconnected succession of phenomena, without the admission of any idea of causative efficiency: some elaborate remarks of the translator, in accordance with the doctrine of the author, are therefore given to exhibit its "falsehood and fallacy." It is said that Dr. Brown confuses and mistakes the two distinctly different conceptions of *uniform antecedence* and *causation*; that he takes the former which is only a *condition* of the idea of causation, for the idea of causation itself, which includes something *more* and *different*, as proved by the consciousness of the relation of muscular motion to the act of volition, and by the usages of all languages, &c., that the idea of cause is that of a doer, actor, producer, changer, mover; and that the degree of motion produced is correspondent to the degree of causative power exerted. An exposition of the doctrine of causation adopted in the transcendental theory of Kant may be found in the article on philosophy by Thomas Wirgman, vol. xx. 'Encyclop. Londinensis' (see 'Causation' in Index, p. 252). By the Kantians the conception of the relation of cause and effect is considered as a synthetical judgment *a priori*—a postulate of pure reason. It is a remarkable fact in the history of metaphysical science, that the speculations of Hume on the idea of causation suggested to Kant the first notion of his system of transcendental ideas, that is, ideas which possess the character of universality and necessity. By Dr. Abercrombie, in his work on the 'Intellectual Powers,' 1832, the subject of causation is considered as belonging to those "first truths," any demonstration of which it is absurdity to attempt (pp. 187-208-214). The following citation is from a learned metaphysical work (Harpur 'On Philosophical Criticism,' 4to, 1810):—"All relation of necessity exists in some quality, property, or attribute which is common to the things related; if things be related as cause and effect, such relation must belong to the predicaments of action and passion: all action implies motion either of body or mind; it is *motion* therefore which, being communicated, is common to the two objects, and is that which constitutes the relation of cause and effect." It would be endless to enumerate works in which the subject of causation is discussed. The treatise of M. Maine de Biran on the relation of cause and effect is highly commended by Cousin. Many works on natural theology and free-will contain more or less on the subject—Hobbes, Clarke, Leibnitz, Collins, Hume, Butler, Cudworth, Edwards, Coplestone, &c.

CAUSE (in Natural Philosophy). We have here only to explain the manner in which this word is used, and not to enter into any speculation upon the connexion of cause and effect. In common language we say that A is the cause of B, when we have observed that B never appears without A having preceded, so that A is always followed by B. And, generally speaking, we are in the habit of assuming the phenomenon which comes first to be the cause, and that which comes afterwards, the effect. In natural philosophy, the word *cause* is used in two senses, which may be distinguished into *true* and *hypothetical*; and it is found convenient for distinction to latinise the former term into *vera causa*. 1. By a *vera causa*, or *true cause*, is meant that which is actually concerned in producing the effect. Thus the rotation of the earth is a *vera causa* in the production of day and night; and similarly, what we call attraction is a *vera causa* in the production of the celestial motions.

2. There are two different ways in which the word *cause* is used in the sense which we distinguish by the word *hypothetical*. (I.) The first is when we are able to prove that phenomena take place exactly in the manner and to the extent which would necessarily happen if a certain supposition were true; so that we cannot be led into error *as to results*, if we assume that supposition to be true. Thus the supposition of the stars being all fixed in an immense crystal sphere, which sphere is turned round from east to west, is one from which the apparent motions of the stars, such as they are, would necessarily follow, and, being frequently applied to the explanation of the details of the heavenly motions, is then assumed as an hypothetical cause. And when it is found that the motions of all the planets are precisely such as would take place if the sun attracted them all, and they each other, as implied in the word gravitation, then the attraction which is sufficient to produce the effects in question is assumed as an hypothetical cause. Thus in the old disputes about the motion of the earth, each side admitted that the other produced an unobjectionable hypothetical cause, and the point in question was, which had the *vera causa*. And formerly it was discussed whether gravitation was a primary quality of matter, or whether the intermediation of other matter was necessary. The second supposition involved the attempt to explain gravitation, by introducing some other quality of matter as the *vera causa*, in place of the hypothetical attraction. And the doctrine of immaterialism [BERKELEY, BIOG. DIV.] is an attack upon the notion of *matter* as a *vera causa* for the phenomena of the external world, though as an hypothetical cause it is admitted as an unobjectionable mode of speaking.

(II.) A phenomenon is cited as the hypothetical cause of another, when the two are always found together, and the nature and quantity of the second are connected by an invariable law with the nature and quantity of the first. In this sense we have seen, in the article CAPILLARY ATTRACTION, that because convexity and depression always go together, and also concavity and elevation, the depression is

referred to convexity, and the elevation to concavity, by the same sort of language as would be used if the first of each couple were the *vera causa* of the second. This is a language of convenience, but is apt to be misinterpreted.

Questions as to whether hypothetical causes are true or not, do not now occupy the attention of philosophers to the extent which was formerly the case. When the motions observed to exist in any system are sufficiently known, the pressures or other admissible species of action which would be sufficient to produce these motions are at once substituted as hypothetical causes. Thus, though the connexion between magnetism and electricity renders it an object of curiosity to trace them to some common hypothesis, few, we imagine, would attempt to find the *cause* of magnetism in the sense of the *vera causa*. It is otherwise when an hypothetical cause is found not to be sufficient to produce all observed effects. For example, the *undulatory* theory of light has prevailed over the *emission* theory, not because we have less reason to suppose that light is an emanation of particles from the sun and stars than existed a hundred years ago; but because it is found that many lately discovered facts are *not* such as would be true if light were an emanation, but *are* such as would be true if it consisted in undulations excited in an elastic medium. And though this cannot but favour the supposition that the undulations are the *vera causa*, yet that remains only a probability; the certainty is that the phenomena of reflexion, polarisation, &c., as hitherto observed, are all such as would necessarily follow, if the theory of undulations were true.

It must appear at first that this application of the word cause makes the ultimate end of natural philosophy much less imposing, if not less important, than the more common idea; which consists in supposing that the reasons (*veræ causæ*) of phenomena are discovered. But whether this be so or not, it is the only rational and demonstrable method of using the word. And it must be observed that all similar phenomena are thus, as it were, bound up together, and made to belong to one system. If then we refuse to say, with many popular works on physics, that "Newton was the first who found out *why* water runs down-hill," we conceive that we are not altogether without a substitute when we say, that Newton was the first who connected the motion of water down-hill with all the motions in the solar system in such a manner that any new information as to any one of them can be extended to all.

But the great use of hypothetical causes lies in this, that they tell us, as long as they last, what to look for. The cause being assumed, the application of mathematics points out the time or circumstances under which to look for new phenomena, or to look at old ones in a new light. Thus several phenomena with regard to light, which might have remained long unobserved, have been predicted by computation from the undulatory theory, and subsequently verified. And in the planetary system, several motions too small to be easily detected, except by a person who previously knows in what manner and at what time to watch for them, have been added by theory alone to the list, and verified by observation; and it is by such means that Neptune and some of the asteroids have lately been discovered.

The language of causation is sometimes misapplied in this way; the proof that a thing is, is called the reason why it is. Thus we remember seeing in the notes to Simson's edition of Euclid an assertion that geometry gives the reason *why* two sides of a triangle are greater than the third, whereas we never could detect anything more than the proof that they *are* so. Another misuse of the word has been pointed out by Dr. Reid. "In natural philosophy," he says, "when an event is produced according to a known law of nature, the law of nature is called the *cause* of that event. But a law of nature is not the efficient cause of any event; it is only the rule according to which the efficient cause acts." Hence, it is not right to say that the *cause* of the acceleration of force in gravitation is that bodies move towards each other with a velocity which varies inversely as the square of the distance.

CAUSTIC. A term used in Pharmacy, chiefly to denote nitrate of silver (*lunar caustic*) and hydrate of potash. In chemistry it is applied as a prefix to the names of the alkalies and alkaline earths: thus we have caustic potash, soda, or ammonia, and caustic baryta, strontia, lime or magnesia; by which is understood, in the case of the alkalies, their compounds with water, and in the case of the alkaline earths, either the pure substances themselves, or their compounds with water.

CAUSTIC (in Optics). When a number of rays proceeding from a point are reflected or refracted at or through any number of media, they will not, in most cases, be all thrown to the same point again, but will be dispersed in such a manner as to touch some curve or surface depending for its form and position upon the position of the luminous point, and the form and position of the reflecting or refracting surface. This curve is called the *caustic* of the surface. We will give a case of the most simple kind. A reflecting curve ABC of a semicircular form receives rays coming from a point on BO produced but at so great a distance, that they may be considered as parallels. The rays $I, II, III, \&c.$, strike the semicircle at $(1), (2), (3), \&c.$, and are then reflected in the directions $(1)1, (2)2, (3)3, \&c.$ The curve AMC , having a cusp at M , is constructed in such a manner that any ray whatsoever moving parallel to zB , shall, after reflection at the circle, touch or graze this curve, which is therefore called the *caustic*

by reflection from parallel rays of the semicircle AMC . And the space AMZ will not be illuminated by any of the reflected rays coming from

any point on AB , but only by those which come from a part of BC , which, after touching CM , their branch of the caustic, proceed and cut through AM . The consequence is, that the space $AMCB$ will be much more highly illuminated than the exterior space; an effect which may be rendered visible by placing a ring, with a bright interior surface, or a piece of steel spring highly polished, upon a table, in the sun-light. It will then become evident, by a part of the table within the ring, of

the form $AMCB$, becoming brighter than the rest, that the greater portion of the reflected light strikes the table within such a curve. Caustic curves are often well shown at the bottom of cylindrical vessels of china or earthenware, when favourably situated with respect to the sun or the light of a candle. In such cases the depth of the vessels causes the rays to fall too obliquely on their cylindrical surfaces, but by inserting a circular piece of card or white paper about an inch beneath their upper edge, or by filling them to that height with milk, the caustic curves can be finely exhibited. Caustics by refraction can be produced by exposing a glass globe full of water, such as the belly of a round decanter, to the rays of the sun, or the light of a candle, and receiving the refracted light on a sheet of paper held nearly parallel to the axis of the sphere, or in such a way that its plane may pass nearly through the luminous body. Under such circumstances there will be seen on the paper a luminous figure bounded by two bright caustics forming a sharp cusp or angle at the focus of refracted rays. These curves are evidently produced by the intersection of the rays, which being incident on the sphere at different distances from the axis, are refracted to foci at different points of the axis, and thus cross one another.

The point which it is of most importance to notice in relation to caustics is the following: It is usual to suppose, for the sake of convenience, that all reflected or refracted rays converge to a point. This is practically true; or rather we may say that such a number of rays are collected by mirrors and lenses so near to a point, that the effect of a complete convergence is produced. If we look at the diagram, we see that all the rays which enter between I and III are far from being nearly reflected to a point, but are scattered along the caustic from 1 to 3 . But an equal number of rays entering between V and VI is collected between 5 and 6 on the caustic, very near to M . The consequence is, a sufficient convergence of rays near M to give a bright image of the luminous point whence the rays came, in the formation of which it is evident that only the parts of the mirror near B will be efficient. No curve except a parabola would, in the circumstances of the diagram, make every ray converge accurately to one point.

A complete theory of caustics would include that of telescopes and microscopes of every kind; but would be of no practical use, except so far as relates to the cusps and the part of the curve near them. These curves were first considered by Tschirnhausen, who gave them their name, and afterwards by John Bernoulli. They are much treated of in the older English works on optics, in a geometrical manner. The algebraical question, in its most general form, has been investigated by

Malus in his 'Théorie de la Double Réfraction,' Paris, 1810; and more recently by Professor Hamilton, in two papers on 'Systems of Rays,' published in the Transactions of the Royal Irish Academy. The question of EVOLUTES is nearly akin to that of caustics.

CAUSTICS. [ESCHAROTICS.]

CAVALIER was formerly an ordinary English term for a horse-soldier; but it has an additional and historical meaning by having been assumed by, or given to, the adherents of Charles I. in the civil war, to distinguish them from the *Roundheads*, the name given to the adherents of the Parliament.

CAVALIER, a work whose rampart is raised several feet above those of the fortress in which it is formed. It serves either to defilade those ramparts from the fire of an enemy on a neighbouring height, or to afford a plunging fire into the trenches of the besiegers. It is generally constructed on the terreplein of what is called a full bastion, and sometimes upon the rampart of a curtain; its form, on the plan, was originally semicircular, but the cavaliers in bastions are now built with straight faces and flanks parallel to those of the work in which they are placed.

A cavalier thus formed and situated is proposed by Cormontaigne as a retrenchment in a bastion. He recommends that on its exterior, along the two faces, there should be a ditch whose sides have revetments of masonry; and that the ditch should be defended by traverses connecting the faces of the cavalier with those of the bastion, near the shoulders of both. The great disadvantage of cavaliers is, that they take up the whole of the available space in a bastion, and crowd the defenders.

Trench cavaliers are works raised by the besiegers on the glacis of a fortress, in order to enable them to direct a plunging fire of musketry into the covered way. They are formed of successive steps, revetted with gabions in tiers above each other.

CAVALRY (remotely from the Latin *caballus*, 'a horse,') is that class of troops which serve on horseback; and, in the British army, it consists of the two regiments of Life Guards, the royal regiment of Horse Guards, seven regiments of Dragoon Guards, and eighteen regiments of Light Dragoons, of which the 7th, 8th, 10th, 11th, 15th, and 18th, are Hussars, and the 9th, 12th, 16th, and 17th are Lancers.

Among the ancients, while warfare consisted in expeditions to remote places rather for plunder than conquest, a numerous cavalry was indispensable. In proportion however as the art of war improved, this class diminished in value: the strength of the Greek and Roman armies lay chiefly in the firm array of their foot-soldiers, and Folard observes, that the most certain evidence of decline in the military character of a state is the existence of a numerous cavalry. A well-disciplined cavalry has however often turned the scale of fortune in war: cavalry contributed greatly to the conquests of Philip and Alexander, and the superiority of Scipio over Hannibal in cavalry was the cause of the victory at Zama. In modern times, Seidlitz gained by his cavalry the battle of Rosbach in 1757: and the victory at Wurzburg in 1796 was decided by the same arm.

In the early French monarchy, and in the Anglo-Saxon kingdoms of Britain, the men of wealth and noble birth distinguished themselves in the field from those of inferior rank by being well armed and mounted on horses. And during several centuries in which the poverty of the nations prevented princes from maintaining standing armies and when the foot-soldiers were men undisciplined and ill-provided, and summoned from the plough to attend the sovereign for a short time only, it is evident that a class of troops comprehending those men who, by the tenure of their estates, were required to serve in the wars at their own charges, and to bring into the field a number of dependents mounted like themselves, and trained in the daily practice of martial exercises, must have constituted almost the only efficient arm of battle.

In France the superior classes of these warriors bore the title of knights bannerets, and the others were designated knights of the second order, or *bas-chevaliers*. In those days the infantry, for the reason before-mentioned, being held in little estimation, the strength of armies was denoted by the number of banners and pennons under which the knights and their attendants fought; victories also were distinguished only by the number of men of rank who had been slain or made prisoners.

But the power of the nobles becoming too great for the monarch, and their mutual jealousies constantly involving the nation in the miseries of civil war, Charles VII., in 1445, took advantage of the temporary tranquillity which reigned in France after the English had been compelled to abandon nearly the whole of that country, to reduce his military force. From that time the kings retained in constant pay fifteen companies, as they were called, each consisting of 600 horsemen, besides the young men bearing the title of archers and pages, who also in general fought on horseback, but were clothed in a lighter armour. The troops composing the companies appear to have been what would now be called gentlemen; and the esteem in which they held themselves is evident from the refusal of the Chevalier Bayard, on the ground of their quality, to unite them with the *Lansquenets* (German infantry) at the siege of Padua, in an assault proposed by the Emperor Maximilian to be made on the place.

More than a century before the time of Charles VII., the English cavalry in the pay of the state was divided by Edward III. (1324) into

small bodies, commanded by officers called constables; and Grose observes, that the list of the army at St. Quintin (1557) is the first in which a body of cavalry is distinguished by the appellation of a troop; a name which is still given to the half of a squadron, or the eighth part of a full regiment.

The respectability of the French companies above mentioned seems to have declined from about the time of Francis II., men of a lower grade being then occasionally introduced, from the difficulty, it is said, of filling with men of high birth the ranks, which were become very numerous.

But the employment of artillery in the field deprived this heavy-armed cavalry of all the advantages it possessed over the soldiers who fought on foot, and the latter were often enabled to maintain the combat after the horsemen were dismounted or forced to retire; hence they gradually rose in reputation, and the good discipline and conduct of the Swiss infantry in the Italian wars induced the French and Germans to augment the number of the troops of this class in their armies. From that time the cavalry, though always an essential arm in war, may be said to have been inferior in importance to the infantry.

It appears that light cavalry did not before the age of Louis XII. exist as a distinct body having general officers and a staff; but Montluc, in the reign of that monarch, mentions a general of 1200 light horse; and the corps must have subsequently become numerous, for it is said that Henry II., in 1552, had 3000 such troops under his command in his expedition to Germany.

The Dragoons are intermediate between heavy and light cavalry, trained to act either on horseback or on foot, as may be required. Père Daniel ascribes their formation to the Maréchal de Brissac, when he commanded the French armies in Piedmont at the end of the 16th century. The practice of horsemen fighting on foot is however very ancient: the Roman cavalry are said to have done so at the battle of Cannæ; and Procopius relates that one of the generals of Justinian, in an engagement with the Persians, caused his horsemen to dismount, and oppose their lances to the enemy's cavalry. Dragoons appear to have been introduced into the English service before the middle of the 17th century; but the oldest regiment of dragoons in the army is that of the Scotch Greys, which was raised in 1681. Dragoons perform the duty of advanced guards and patrols; they escort convoys, and harass the enemy in his retreat; or, in reverses, they protect the dispersed and defeated infantry. The name Dragoon arose from the weapon with which they were armed. [ARMS: *Dragon*.]

Hussars are also a species of light cavalry, which originally constituted the national militia of Poland and Hungary. In France they were formed into a corps in the time of Louis XIII., under the name of Hungarian cavalry; and the class of troops was subsequently adopted in this country. It is uncertain whence they obtained their present denomination, but probably from the shout they formerly gave before beginning action. They are now employed to protect reconnoitring and foraging parties, to serve as patrols, and to perform all the ordinary light cavalry duty.

The Lancers were introduced into the British service in order to correspond to the corps of what were called Polish Lancers in the French army. The long lances carried by this class of troops were supposed to be of use in a charge against infantry, and the fluttering of the flag at its extremity, by alarming the horse, to give an advantage over a dragoon otherwise armed.

In the last war with France, a portion of the French cavalry was furnished with cuirasses, and, in imitation of them, the English Life Guards have since borne the same heavy armour. These troops carry only a sword and a carbine; the heavy cavalry in general carry carbines and swords; and the light cavalry, with the exception of the Lancers, who besides the lance carry a sword and pistols, the same. The carbine with which the English cavalry is armed is a short breach-loading rifle. A complete regiment of cavalry is divided into four squadrons, and each of these into two troops. The full strength of a troop is 80 men; and to each troop there is appointed a captain, a lieutenant, and a cornet.

CAVEAT. As a general term in law, a caveat denotes a formal notice or caution given, by a party interested, to a court, judge, or public officer against the performance of certain judicial or ministerial acts. Thus caveats in this general sense were entered formerly in the Court of Chancery against the passing of a patent; and in the Court of Common Pleas against the levying of a fine. In a more confined and technical sense, a caveat signifies, 1. A caution entered in the Court of Probate to stop the granting of probates of wills or of administrations; and 2. A notice given to the bishop by a party who disputes a particular right of presentation, to prevent the institution of a clerk to a benefice. A caveat in the former case is for six months; in the latter binding for three; and an institution made, pending the caveat, has been considered as wholly void by that law. The effect of a caveat on the Court of Probate, is to entitle the person entering it to notice of any application for probate or administration, so that he may appear and oppose it (20 & 21 Vict. c. 77; 21 & 22 Vict. c. 95; 'Rules and Orders of the Court of Probate,' 1858).

CAVIAR (French, *Caviar*, *Cavia*; German, *Kaviar*; Italian, *Caviario*, *Caviale*; Spanish, *Caviario*; Russ. *Ikra*); an article of food prepared in Russia from the roes of some large fish, generally the

sturgeon. The greater part of the caviar is prepared near the mouths of the Volga, and also at the mouths of the Danube, Dnieper, and Don. In the month of March, the sturgeon arrives in great numbers for spawning at these places. The ovaria of the largest of these fish are estimated to contain 3,000,000 of eggs. The fish are caught both with nets and with hooks. Caviar is prepared by removing from the roe all its membranes; it is then washed in vinegar or white wine, and dried by being spread on a board in the air. After this, it is thoroughly salted, the salt being rubbed in with the hand; it is then put into a bag and pressed in order to remove the liquor; finally it is packed in kegs, and is then ready for sale. The caviar made on the shores of the Caspian is for the most part sent up the Volga to Moscow; that shipped from the ports of the Black Sea and Sea of Azof is bought at Astrakhan by the Armenians of Nakhitchivan and the Greeks of Taganrog. This caviar is not so good as that which is made on the Caspian. The principal exports are to Italy; very little is brought to England. The shipments altogether form only a small part of what is made, the consumption in Russia being very great in consequence of the three seasons of fasting which occur in the year. There has been known to be as much as 1000 cwts. of caviar shipped from Odessa in a single year; but this is far beneath the produce of the Caspian, which has in some years reached 15,000 cwts. When of good quality, caviar is dry and of a brown colour; it is commonly eaten with oil and lemon-juice. A cheaper and less prized kind is obtained from the roe of the gray mullet, and from some species of carp, which are common in and near the Black Sea.

Although not known by the name of caviar, there are several other articles of food similarly made from the roe of fish. One is called *botargo*, made on the coasts of the Mediterranean from the spawn of a species of mullet, especially at Tunis, and in Sicily; it is prepared nearly in the same way as caviar. In the islands of the Indian Archipelago, a considerable trade is maintained in the roe of a large species of chad or shad, found in the rivers of Sumatra. Some of the American Indians gather herring-roes as an article of food; at certain seasons of the year they sink cedar-branches to the bottom of a shallow river by means of heavy stones, and by the next morning the green foliage of the branches is found to be covered with herring-spawn; the Indians wash this off into a water-proof basket, squeeze it by the hand into little balls, dry it, and eat it as a very palatable food. Mr. Simonds thus describes the mode adopted by the Spaniards of Central America in curing the roe of the callipera fish. "They first rub the roe well with salt and a little nitre, then they put a number of them one upon another, and compress them by means of a heavy weight. After this they build up a sort of stove of green boughs, covering the top with green branches intersecting each other. The inside being filled with straw and fresh leaves, they ignite these, place the roes on the top, and cover them well up with green boughs. The roes are allowed to remain six or seven days in this state, during which time the fire keeps smouldering and sending up a thick smoke; this smoke is concentrated on the roes by the upper layer of branches. The membranous covering of the roe is not taken off; and thus, the air being excluded, the roe will remain good for a long time. When the roe is to be eaten it is cut in very thin slices; the outer coating is even then not taken off, but is rubbed clean with a dry cloth."

CEDAR-WOOD, OIL OF. The essential oil of cedar-wood contains *cedrole*, a crystalline solid, of the formula $C_{25}H_{28}O_2$, dissolved in a liquid hydrocarbon termed *cedrene*, and having the formula $C_{32}H_{40}$.

CEDRENE. [CEDAR-WOOD, OIL OF.]

CEDRIRET, one of the products of the distillation of coal tar discovered by Reichenbach. It is a volatile solid, and is obtained from creosote by the action of potash and acetic acid. It crystallises in a solution of sulphate of iron, forming orange-red crystals, which dissolve with a blue colour in sulphuric acid. The colour of oil of tar seems to be owing to this substance.

CEDROLE. [CEDAR-WOOD, OIL OF.]

CELERY, or **APIUM GRAVEOLENS**, is a wild umbelliferous plant by no means uncommon in the marshes of England, especially near the sea; in the isle of Thanet it is abundant. In its native station it has the character of being a poisonous plant, but transplanted to a garden it becomes an agreeable and wholesome vegetable. This is in conformity with the general properties of umbelliferous plants, in which two principles, the aromatic and the narcotic exist, and which are food or poison as the one or the other predominates. The narcotic is generated abundantly in moist places, and the aromatic principally in dry situations; and hence plants that are dangerous while growing in marshes, become wholesome when transferred to dry places. This appears to be one cause of the difference between the wild and the cultivated celery; another is, that the latter is blanched before it is brought to table, and thus the secretion of its deleterious principles is prevented.

Of garden celery there are many varieties; the best of which for salad is the Turkish, and for stewing, the Celeriac or the turnip-rooted sort. For soups, the "seeds" may be employed with as much advantage as the stems or leaves.

Celery is raised in beds, from seed sown from the end of March to the beginning of May, and requires a light, rich, well-drained soil. When the plants in the seed-bed are about two or three inches high, they are pricked out into another bed, where they remain till they are

six or seven inches high; they are then transferred to trenches, in which they are placed in a row, and finally left. As they advance in size, they are gradually and carefully earthed up, till at last the whole length of the stem under ground is sometimes as much as four feet. The goodness of celery depends essentially upon its growing rapidly, being kept well drained from moisture, and having a solid stalk to its leaves. Celeriac is not earthed up, but is grown upon the surface of the ground, and kept free from weeds and preserved from the emission of strong lateral roots by frequent hoeing.

CELESTINES, ORDER OF, a monastic order, instituted about 1254 by Pietro da Morrone, afterwards Pope Celestine V., from whom they took the name of Celestines. Their first convent was at Murrone, in the Apennines of Abruzzo. It was a reform of the order of St. Bernard. Urban IV. approved its institution, and Gregory X. granted many privileges, with an exemption from payment of tithes, &c. It became a very rich order, both in Italy and France. In 1770, in consequence of an order from Louis XV., the Celestines of France held a capitulum, or general assembly, from the various houses they had in that country, to consider of several reforms in their discipline and economy, which were insisted upon by the king. These however they refused to adopt, and preferred the secularisation or suppression of their order, which was ultimately effected by Pius VI. in 1776-8. Their property was taken possession of by royal commissioners, a suitable pension being allowed to each monk. Some years after, Ferdinand IV. of Naples suppressed the Celestine convents in his kingdom.

CELLA. [TEMPLE.]

CELLULOSE ($C_{24}H_{20}O_{10}$). The different parts of all plants are built up of little cells or vessels somewhat after the manner of honeycomb, but more varied in shape. The walls of these chambers are universally composed of one substance, called cellulose. Its chemical composition is the same from whatever source obtained; it may, however, differ considerably in appearance and physical character. Thus in the hard shells and kernels of various fruits, such as the cocoa-nut, peach, or filbert, it is very dense; in hay and straw, tenacious and rigid; in hemp and flax, elastic; while in the pith of the rush or elder we have nearly pure cellulose in a spongy condition. It is also found as one of the proximate constituents of inferior animals, for example, in the tunics of ascidia and other molluscs.

Pure cellulose may be obtained from pith, old linen, finely carded cotton, or the better kinds of filtering-paper, by successively treating with boiling water, dilute alkali, chlorine, acetic acid, alcohol, and ether, and drying at a temperature of 212° Fahr. In this state it is a white solid; semi-transparent, tasteless, and odourless, and insoluble in cold water, alcohol, ether, or the fixed or essential oils. Boiling water very slowly converts it into dextrin. Concentrated sulphuric or phosphoric acid converts it first into dextrin, and, on dilution with water and ebullition, into glucose (grape-sugar).

When unsized paper is immersed for a few seconds in strong sulphuric acid diluted with half its volume of water, it is converted into an exceedingly tough substance resembling parchment. This extraordinary change is entirely molecular, the chemical composition of the cellulose remaining unaltered.

Concentrated nitric acid converts cellulose into an exceedingly combustible substance [GUN-COTTON], in which the elements of nitrous acid (NO_2) replace part of the hydrogen in the cellulose. Strong caustic potash or soda causes it gradually to swell and finally disintegrate.

When moist cellulose and hydrate of potash, in equal proportions, are heated under slight pressure, hydrogen is evolved, wood-spirit distils, and formate, acetate, and carbonate of potash remain.

When cellulose is heated to about 400° Fahr. in contact with solid caustic potash, oxalic acid in large quantity is formed. Caustic soda does not produce the same effect.

Iodine does not colour cellulose until the latter has been acted upon with sulphuric acid, when a fine blue is produced. This reaction is of service in microscopical investigations, but prolonged action of the acid should be avoided.

Medulline, *fungine*, and *suberine* are but physical modifications of cellulose.

CELT, an instrument of stone or bronze, found in tumuli and other primeval earthworks. From being discovered in burial-places, and, among remains usually known as Celtic, these instruments are frequently supposed to have been called *celts* because of their employment by the Celts; but the name appears to have been given to them from an old Latin word, *celtes*, a chisel, in which sense the word is used in the Vulgate (Job xix. 24) and elsewhere.

The term celt has been somewhat indiscriminately applied to several kinds of cutting instruments: to small hatchets, axes, and even what appear to be military weapons, as well as to chisels; but the term is now restricted to chisels, or small instruments similar in character. Worsaae and some northern antiquaries would, indeed, confine the term to "instruments hollowed out to receive a wooden handle;" but in this he is not followed by English authorities. The most simple forms of stone or flint celts are extremely inartificial. Some have been merely chipped away, but most have been subsequently polished. They vary a good deal in size, but the common celt is about six inches long, and makes a certain approximation to the form of an incisor tooth; some

are more wedge-like in shape, the cutting end being wider, and of course thinner than towards the haft. That these instruments were used as chisels, the blunt end being fixed in a wooden handle, there can be little doubt; marks such as might be made by a chisel of this kind are still traceable on the canoes and wooden vessels which have been exhumed of primeval date, and instruments of a similar kind formed of jade are used at the present day by natives of the South Sea Islands in hollowing out and carving their canoes, &c. Stone celts are most commonly made of flint, but they have also been found of serpentine, jade, porphyry, sienite, siliceous schist, indurated clay-stone, &c. They are found very plentifully throughout Great Britain, Ireland, and the Channel Islands, and over the entire continent of Europe, and indeed wherever primeval antiquities have been dug up. Examples of them consequently abound in most European museums; the British Museum contains numerous specimens.

Bronze celts are scarcely less numerous than those of stone. They belong to a somewhat more advanced stage of social progress. In form they are more varied; and they must have been more varied in their mode of attachment, some being hollowed out to receive a handle, while others are shaped to fasten into a handle. The hollowed kind have usually an ear or ring attached, which it has been conjectured served to fasten the celt to its handle by means of a thong. Several moulds in which these bronze celts were cast have been found in various places. Numerous examples of bronze celts and moulds will be found in the British Museum.

Much interest has lately been excited by the discovery of "flint-objects," somewhat resembling in form and size the ordinary stone celts, and therefore by some called celts, in those undisturbed beds of gravel, sand, and clay known by the geological name of *drift*, and in what geologists term *bone-caves*. Objects of this kind appear to have been found in the drift at different periods without exciting particular attention,—several, for instance, are recorded ('Archæologia,' v. xiii.) to have been found in gravel 12 feet below the surface at Hoxne in Suffolk in 1797,—but no particular attention appears to have been given to the matter till M. Boucher de Perthes announced similar discoveries made by himself at Abbeville of very large quantities of flint implements, evidently shaped by the human hand, in undisturbed gravel beds at a considerable depth below the surface. M. de Perthes published his discoveries in his 'Antiquités Celtiques et Antédiluviennes,' 2 vols. 1847, but they at first attracted little notice. A second edition of his work appeared in 1857. Within the last few months discoveries of a similar kind have multiplied in a remarkable manner. Objects precisely similar were found in Brixham Cave, Devonshire, among the bones of extinct mammals; and shortly after, Dr. Falconer found them in various caves near Palermo, also in immediate conjunction with bones of large extinct mammals; whilst Mr. Prestwich and other geologists have been equally successful in their researches among the beds of drift in Suffolk, at Abbeville, Amiens, and elsewhere. In fact an immense quantity of these "flint-objects" have been discovered in various parts of England and the continent of Europe, and a great body of information accumulated. The objects differ somewhat in shape from the ordinary celts, are very much ruder, and always unpolished. They have been classed by Mr. J. Evans, one of the most zealous investigators of the drift, in a paper read before the Society of Antiquaries, as: "1. Flakes of flint apparently intended for knives or arrow-heads. 2. Pointed implements, usually truncated at the base, and varying in length from 4 to 9 inches,—possibly used as spear- or lance-heads, which in shape they resemble. 3. Oval or almond-shaped implements, from 2 to 9 inches in length, and with a cutting edge all round: they have generally one end more sharply curved than the other, and occasionally even pointed, and were possibly used as sling-stones, or as axes, cutting at either end, with a handle bound round the centre."

Mr. Evans, it will be seen, feels little doubt of their character; and most of the geologists who have taken part in the inquiry appear equally satisfied as to their being artificial products. The fact is however very far from being generally admitted. Mr. Thomas Wright, Mr. Cull, and other skilful antiquaries have published their reasons for doubting whether they are really works of human manufacture. The bearings of the question with reference to the date of man's existence on the earth are so important that the matter must be thoroughly sifted in every way before any statements can be received as conclusive. On the one hand, it will not be denied that, if found in any of the known places of human resort, or sepulture, their artificial character would have passed unquestioned. On the other, besides the difficulty arising from the extreme rudeness of the articles themselves, there are other difficulties suggested by the conditions in which they are found that cannot be overlooked. They are found amongst the bones of a great number of animals; yet although, as is presumed, objects of human workmanship, no human bones have been found with them; and this is the more remarkable because they occur in such quantities—hundreds together sometimes—and in so many places, that there must have been in the various localities a somewhat dense population to require so many cutting-tools, for whatever purposes they were used. It is, to say the least, a remarkable fact, that neither in the drift nor in the caves has any other trace of the existence of man been found except these rude "flint-objects," and that they should occur in such profusion. But we have no intention to draw any conclusions either way.

Probably before long some facts will be brought to light that will go far to dissipate the difficulties which at present surround the subject.

CELTÆ, the name of an ancient race, which, according to the oldest historical records, occupied a great part of central and western Europe. The Celtæ appear to have been divided into two great families, the Gauls (Galli, in Greek Κελται and Γαλάται), who occupied the country of that name from the remotest epoch on tradition, and who in their own language called themselves Celtæ; and the Cymri, who are by some considered to be the same as the Cimmerians (Κιμμέριοι), who appear to have migrated westwards at a later period from the countries bordering on the sea of Azof, and, advancing along the Danube, to have spread themselves across Germany to the Ocean. The latest inquiries into the Celtic language show a clear affinity between it and the languages called Indo-Germanic by modern philologists. The earlier Greek writers had very confused notions about the Celtæ. Herodotus (iv. 49) places the Celtæ at the sources of the Danube, and in the remotest west of Europe, beyond the Cynetes (an unknown people); but he does not mention them in his enumeration of the various nations who furnished the Carthaginians with mercenaries for their Sicilian wars. In the first Punic war we find Gaulish troops in the Carthaginian service. Eratosthenes named all the north-west of Europe Celtim; and we learn from the inscription found at Olbin, near Odessa, that Celts were settled in the Ukraine (Niebuhr 'Kleine Schriften') probably before the expiration of the second century before Christ. Other Greek writers confound the Celtæ with the Scythians, others with the Germans or Teutones (Fabri 'Thesaurus,' art. Galli et Galatæ, and references there). The messengers who carried to Athens the news of the burning of Rome by the Gauls (B.C. 382, according to Niebuhr), said that it had been effected by a great host of Hyperboreans, who had come over the icy mountains from the unknown regions of the north. (Plutarch's 'Camillus.') But long before this (589 B.C.) the Celtæ of Gaul had crossed the Alps, under Bellovesus, into northern Italy, and had become known to the Romans by the name of Galli, 'Gaels,' which seems to have been an aboriginal name of the oldest tribe of the Celtæ settled in western Europe. Livy and other ancient historians fix the immigration of Bellovesus in the reign of Tarquinius the elder; but Niebuhr is inclined to place it at a much later date. It is evident, however, that there were several immigrations of the Gauls into northern Italy, and at different times. The Galli, who occupied the plain north of the Po, drove away the Etruscans, but they never conquered either the Veneti, who were settled east of the Anthesis (Adige), or the Ligurians, who occupied the country south of the Po to the Mediterranean and the river Macra. The various Gaulish tribes that immigrated into Italy are believed to have belonged to the Ædui, Lingones, Ambarri, and Carnutes, who have left traces of their residence in northern Italy. The Insubres are said by some to have been a division of the Ædui. (Bossi, 'Storia d'Italia,' vol. ii. c. 9.) The Cenomani seem to have belonged to a later immigration; they occupied the country of the Orobii, the previous inhabitants of the hilly region about Como and Bergamo. Cato ('De Origin.') says that the Orobii were not Gauls. The Boii were likewise a later immigration of Gauls, who crossed the Po, and occupied the country south of that river. [BOII, in GEOG. DIV.] Lastly, the Senones spread south-east of the Boii, along the Adriatic coast, as far as Picenum. The Gauls never made a permanent settlement in Italy south of the Apennines.

Contemporary with the first recorded immigration under Bellovesus, another host of Gauls, under Segovesus, crossed the Rhine, and, advancing as far as the Hercynian forest, settled along the Danube, and in the country now called Bohemia, from which they were afterwards driven by the Marcomanni and other Teutonic or German tribes. Some of them penetrated into Illyricum, and settled among the Illyrians. The Scordisci, south of the Danube, appear to have been a tribe of Gauls. In very remote times the Celtæ of Gaul crossed the Pyrenees, and conquered part of Spain, where their descendants, becoming mixed with the aboriginal Iberians, formed the nation known to the Carthaginians and the Romans by the name of CELTIBERI. Some colonies of Celtæ penetrated to the western extremity of Spain, and we find them mentioned in the ancient geographers under the name of Celtici, both on the banks of the Anas (Guadiana) and on those of the Minius (Minho) in northern Lusitania.

The Gauls likewise are said to have crossed the sea into Britain, which they occupied. [BRITANNIA, GEOG. DIV.] But while the Gauls were thus spreading their colonies to the east, the west, and the south, they were themselves pressed upon from the north by the Cymri or Cimmerians, who appear to have been a branch originally of the same stock as the Gauls, and who had occupied western Germany. The Belgæ are believed by some, among whom is Niebuhr, to have been a mixed race of Cimmerians and Germans; Appian ('De Reb. Gall.') says that the Nervii, one of the chief Belgian tribes, were descendants of Cimbrians and Teutones. The epoch of the great Cimmerian immigration is unknown, and there is much confusion in the ancient historical records between the movements of the Cimmerians and those of the original Gauls. We know that the Belgæ occupied the northern part of Gaul and the southern part of Britain, and drove the Gauls farther inland. It appears also that tribes of Cymri occupied the north-west coast of Gaul, for the Veneti of lower Brittany were called Cymri or Cimbrians, as distinct from the Celtic Gauls around them. Diodorus

(v. 32) says, that Belgæ was the old name of the Cymri, and he quotes Posidonius, who calls them Galatæ or Cimbrians, while he calls the Gauls by the name of Celtæ. Ammianus Marcellinus (xv. 9) records as a tradition of the Druids that a portion of the Celtæ came into Gaul from beyond the Rhine, and passed afterwards into south Britain, from whence they drove the original Gauls farther inland. The distinction between Gauls and Cymri has been perpetuated, at least in name, down to our days, in the Gaels of Scotland and the Welsh, the language of the latter being called Cymri, as well as that of the Armoricans, or inhabitants of Brittany, while that of the Gaels of Scotland is called the Gaelic. The Cimbri of Marius appear to have been a tribe of Cymri who had settled in northern Germany, or, according to some ancient writers, among the Scythians, and from them came the Celto-Scythians, who joined the Cimbri in their westward irruption. (Plutarch, 'Marius.') There is sufficient similarity between the manners and institutions of Gauls and Belgians to make them appear cognate races: both had a powerful Druidical hierarchy; both were divided into optimates, or freemen, and the common people, who appear to have been little better than serfs; both were hasty, violent, and impatient (Niebuhr, 'History of Rome,' vol. ii., where he treats of the Gauls and their immigrations); both appear to have been distinct from the Teutonic or German race, as well as from the Iberian and Ligurian.

About 280 B.C. a vast multitude of Celtæ or Gauls invaded Macedonia and Greece. According to Justin they started from Pannonia, where their ancestors had settled long before. It is probable that they were joined by other tribes, either of Celtic Gaul, or of Cymri, coming from western Germany, or of both. Justin mentions among them the Tectosages, from the neighbourhood of Tolosa, but his account is very confused and contradictory. (Compare b. xxiv. 8, with b. xxii. 3.) The invaders were divided into two great bodies: one under a chief, whom Justin calls Belgius, and Pausanias Bolgos, invaded Macedonia, spreading terror and desolation everywhere before them. Ptolemæus Ceraunus, king or usurper of Macedonia, having attempted to oppose them, was defeated and killed. They made an immense booty, plundered the temples without scruple, and then retraced their course homewards. The other host of Gauls, under Brennus, entered Macedonia the following year, 279 B.C., and defeated Sosthenes, who, after the death of Ceraunus, had assumed the government of that country. Brennus then advanced through Thessalia, and southward as far as Delphi, with the intention of plundering that rich sanctuary. The Gauls were however put to flight, partly by the resistance of the people of Delphi, and partly, it is said, by an earthquake, which took place during the attack, and which was followed by a fearful storm. These phenomena were attributed to the wrath of the offended God. The attack on Delphi appears to have taken place in 278 B.C. (Clinton, 'Fasti Hellenici.') Brennus, through mortification, killed himself. The Gauls lost vast numbers in the repulse, and still more in their retreat northwards, being harassed by the hostile populations. Another incursion into Macedonia was made soon after by another host of Gauls, who had not been in the Delphic expedition, but had remained on the frontiers of Pannonia. (Justin, xxv. 1, 2.) After defeating the Getæ and Triballi, they were met by Antigonus Gonatas, and totally routed. The remnants of these expeditions withdrew into Thrace, where parties of Gauls had been in the habit of making incursions, to the great annoyance of the Byzantines. [BYZANTIUM, GEOG. DIV.] Being however invited by Nicomedes I., king of Bithynia, who was then at war with his brother Zibœthes [BITHYNIA, GEOG. DIV.] and being provided by the same with boats, they crossed over into Asia, and effectually supported his claims to the throne.

They then settled in the interior of Asia Minor, to the south-east of Bithynia, and occupied a great tract of country, which from them was called Galatia and Gallogræcia. It was bounded north by Paphlagonia, west by Phrygia and Bithynia, south by Cappadocia, and east by Cappadocia and Pontus. They made frequent incursions into the neighbouring countries, but were checked by Antiochus I., who defeated them, and was in consequence called Soter or Saviour. Three principal tribes of Gauls are mentioned as having settled in the country; the Tectosages, whose principal town was Ancyra; the Tolistobogi, who lived near the sources of the Sangarius, and whose principal town was Pessinus, famous for its temple of Cybele; and the Trocmi, who lived more to the east, near the banks of the Halys. (Leake's 'Asia Minor.') The Galatæ are frequently mentioned in subsequent history as mercenaries in the armies of the kings of Bithynia and of Pontus, and also in those of the later kings of Macedonia and of Syria. They seem to have had their own kings or chiefs, some of whom are mentioned in history; among others, one Cavarus, who acted as mediator between Prusias I. king of Bithynia, and Attalus king of Pergamus. Sestini has given an account of several medals of Cavarus and other kings of the Gallogræci. During the war of the Romans against Antiochus III., the Consul C. Manlius invaded Gallogræcia 189 B.C., for which he obtained the honour of a triumph, 186 B.C. (Livy, 38 and 39.) Mithridates the Great, in his wars against Rome, occupied Galatia, and we find the Galatians forming an essential part of his troops. One of their chiefs, however, Deiotarus by name, forsook the part of Mithridates in favour of Rome, in consequence of which he was acknowledged as king by the Roman Senate. It was for the son of this Deiotarus, called also Deiotarus II., that Cicero pleaded before Cæsar. After this

Galatia became a province of the Roman empire. Several names of places in Galatia attested the relationship of the new settlers to their western brethren, such as Ecobriga, Tolistochora, &c.

The power of the Gauls in Europe was evidently on the decline long before Cæsar's conquest of their country. They were pressed on one side by the Belgæ and the Germans, and on the other by the Iberians, who had settled in Aquitania. The Gauls of Italy had been all subjugated by Rome. The Romans had also occupied the Province of Narbo, which originally belonged to the Celtic Gauls. For the names and localities of Celtic Gaul in Cæsar's time, see CÆSAR, in BIOG. DIV.; and for those of the Celtæ of Britain, see BRITANNIA, in GEOG. DIV.

The distinguishing features, both physical and moral, of the Celtic race, whether Gauls or Cymri, are described by most ancient writers, especially Cæsar, Livy, Diodorus, Appian and Justin; but their accounts are not free from contradictions. They were men of large size, of fair complexion, reddish hair, and fierce aspect; they wore their hair long, with moustaches, but most of them showed the chin. They could bear cold and rain, but not heat or thirst. They were vain and boastful, clamorous and impatient of control, and quarrelsome among themselves. Their first onset was formidable, but if once repulsed they easily gave way and dispersed. Their swords were long and unwieldy; those of the Celtic Gauls appear to have been made of copper, but they bent after the first blow, which gave a great advantage to the Romans over them: some of them also used lances with iron heads, and the bow was not unknown to them. The Gauls fought generally naked down to the loins. Their shields were large and oblong; but they appear to have been slight and ill contrived for protection. Livy (xx. 46) well describes the contrast between the appearance of the Gauls in Hannibal's army and that of the Spanish mercenaries. Their dress was a striped or coloured jerkin, hose and trousers fastened with a girdle in many cases of gold and silver, with an over-coat, also coloured, of varied materials for summer or winter. Their government was aristocratic; the optimates or nobles formed the senate or supreme council: the common people seem to have had no political rights, and to have been in a state of depression. We find that one more powerful tribe, such as the Bituriges and Ædui, exercised, at least for a time, a sort of political supremacy over the neighbouring tribes. Their kings or chiefs appear to have been elective, and to have held their office only for a year or two, unless re-elected. The Druids formed a powerful hierarchy; they were interpreters of the law, and judges in civil and criminal matters. The Druids seem to have been an hereditary caste, though not exclusive, being recruited from the young men of noble families who resorted to their academies to study. Cæsar ('De Bello Gall.' vi. 13) gives a good sketch of the institutions of the Gauls in his time, which he contrasts with those of the Germans. He says that Druidism was supposed to have come from Britain into Gaul. The religion of the Celtæ was originally a sort of theism; they had no idols or images, against which they showed a particular aversion in their invasion of other countries; they worshipped the Supreme Being in sacred groves. The oak and the mistletoe were sacred. They afterwards adopted some of the gods of the Germans and other nations. They had also bards, who were not only poets but soothsayers, and their songs were transmitted by tradition. The Druids offered human sacrifices, and they drew omens from certain appearances in the limbs and blood of the victims, and also from the flight of birds. The latter was resorted to in case of emigration to direct their course. Diodorus (v.) says that the Druids had instruments by which they could bring distant objects either on the earth or in the heavens, nearer to them. He tells some wonderful stories of the Celtæ or Gauls, which show how little that people were known at Rome even in his time. He says that "those who inhabit farthest north towards Scythia are the most ferocious, and they are said to devour human flesh, like the Britanni who inhabit Irin (Ireland)." The Celtæ of Gaul had attained a considerable degree of civilisation and luxury when Cæsar entered their country. They seem to have been acquainted with the Greek language by means of the colony of Massilia (Marseille), and the Greek alphabet was in use among them. We do not know of any original Celtic alphabet, nor of any works in their language. Indeed we have no knowledge left of the language of Celtic Gaul, unless we suppose it to have been similar to the Gaelic of Scotland. The Breton language, like the Welsh, is a dialect of the Cymri language belonging to that great division of the Celtæ. It was long disputed whether the Basque language was a dialect of the old Celtic, but it is now generally conceded that the two are not related. The remains of the old Celtic language must therefore be sought in the Gaelic, and in the Erse or Irish, which is said to resemble the Gaelic; and in the Welsh and its cognate dialect, the Breton. These seem to be the only probable offspring of the Celtic Gaul and the Cymri, Cimmerian, or Cimbrian. For a large collection of authorities respecting the Celtæ and their various branches, see Forbiger's 'Handbuch der Alten Geographie,' vol. iii. 1848.

CELTIBERI, a people of ancient Spain, supposed to have been descended from Celtæ, who in remote times immigrated from Gaul, and afterwards became mixed with the native Iberians, so as to resemble in their habits more the latter than the former people. The Celtiberi extended from the right or south-west bank of the Iberus (Ebro) towards the interior of Spain. They occupied the highlands

about the sources of the Duero and the Tagus, and both sides of the great central ridge which divides the waters which flow east towards the Mediterranean from those which flow west into the Duero and the Tagus. The Celtiberi are spoken of by the Greek and Roman writers sometimes as a single people, sometimes as a confederation of various nations. In the latter sense they extended over a great part of central Spain, including the Arevaci, Peledones, Lusones, Belli, and Tisthi. Appian places even the Vaccaei among the Celtiberi, but according to Niebuhr they were pure Iberians. Numantia, in the country of the Arevaci, is said by Florus to have been defended by 4000 Celtiberi. The principal towns of the Celtiberi were Segobriga, not far from Numantia, and different from the Segobriga, now Segorbe, near Valentia, Turiaso, now Tarazona Bilbilis, the birth-place of Martial, now Calatayud; Argobriga, &c. The Celtiberi were a brave people, superior, in firmness, to the Lusitani, who were chiefly pure Celts, and they proved formidable both to the Carthaginians and the Romans. After having submitted to Rome in the second Punic war, they repeatedly resumed the contest, fought against Fulvius Flaccus, were subjugated by T. Sempronius Gracchus 179 B.C., revolted a few years after again under the prætorship of Appius Claudius, and were again defeated. They fought afterwards against C. Marcellus and Licinius Lucullus. After the destruction of Numantia by Scipio Æmilianus they were finally subdued. Their country became part of the Roman Provincia Tarraconensis. (Appian. 'De Rebus Hispan.'; Livy, &c.)

CELTIC ARCHITECTURE. Under this term are classed the structures, or collections of stones, which are usually considered to be the work of the natives of our island anterior to the arrival of the Romans. But very few, if any, of these structures have any claim to be regarded as architectural works. The beginnings of architecture are, however, undoubtedly perceptible in the series of stones, each consisting of two uprights and an impost, which form so striking a feature in the circles of Stonehenge: but they are only the beginnings. The upright pillars have evidently undergone shaping; and the mode in which the imposts were secured by mortises and tenons, shows a regular principle of construction. Something, also, of architectural arrangement is exhibited in that very remarkable group of stones, and in the far more extensive, but ruder series, at Avebury in Wiltshire and Carnac in Brittany. But the ordinary stone circles and cromlechs of this and other countries are mere rude collections of unhewn stones.

The objects chiefly understood, when Celtic remains are spoken of, are the stone circles mentioned above, cromlechs, kistvaens, and upright stones,—all of which are of the kind once generally, and still very frequently, termed Druidical; the circles being regarded as Druidic temples, the cromlechs as Druidic altars. Stonehenge, the most perfect and the most finished of the stone-circles now remaining, and Avebury, the most extensive relic of the kind left in this country, will be found fully described (and the conjectures as to their purpose examined) in the GEOGRAPHICAL DIVISION of the ENGLISH CYCLOPÆDIA; Stonehenge under WILTSHIRE, vol. iv., cols. 1139-41; AVEBURY under that title, vol. i., cols. 743-6; and the great circle at Carnac under MORBIHAN, vol. iii., col. 863. CROMLECHS will be treated of under a separate heading in the present Division; and the small circles of stones which formed the boundaries of barrows or tumuli, and kistvaens, which are the stone chests or frames which were placed within the barrows, will be spoken of under TUMULI; and under those heads the several purposes they were intended to fulfil, and the state of civilisation of which they are the evidence, will be most conveniently examined. Here it will be enough to add, that whilst circles, upright stones, and cromlechs are found very widely distributed throughout Europe (and objects bearing a marked resemblance, if not a very near affinity to them, are found in other parts of the world also), no remains of any houses or buildings, properly so called, of the Celtic period, have been discovered. The "Pen-pits" described by Sir R. Colt Hoare, and by him called British Houses, can at best have only been the foundations of houses of which the superstructures (which, if we may trust Diodorus Siculus, were ordinarily among the Britons only built of reeds or wood) have perished.

CEMENT. At the present day the term cement is specifically applied to those building materials used for the purpose of connecting small stones, or bricks, which set very rapidly; and in this respect cement differs from lime mortar, for the rate of setting of the latter is essentially slow and progressive. Cements themselves are subdivided into the *calcareous*, and the *gypseous*, and into the *natural* and *artificial*; perhaps also a mixed class of iron, glass, oil, and bituminous cements might be added to these, but their use is very limited.

The natural calcareous cements are those obtained by the calcination of the argillaceous limestones, in which the silicate of alumina is present in the proportions of from 30 to 60 per cent. of the whole mass, though in the best materials of this description the proportion of the silicate rarely attains even 50 per cent. It appears that after a stone of this description has been deprived of its carbonic acid gas, and its water of crystallisation, by the process of calcination, it is susceptible of forming, by the addition of water, a new hydrated double silicate of lime and alumina, with very great rapidity; and that the combination so formed is of a very permanent character, and of great hardness and tenacity. The degree of heat required for this calcination is moderate, in the case of the natural cements, and the stone loses in the kiln about

one-third of its natural weight. It is then ground, and packed in as airtight a manner as possible in casks; for the powder thus obtained has a great affinity for moisture, and it absorbs readily that which may be in suspension in the atmosphere. The cements made, and treated, in this manner are usually known in commerce as the Roman cements, and those sold in England are obtained by the calcination of the nodules of septaria dispersed in the liassic, the Oxford, or the tertiary clays. Similar nodules are found in the clays of the oolitic series near Boulogne, at Pouilly, Vassy, &c., in France; and in the United States and Canada. As the composition of the nodules used in the manufacture of the English natural cements represents the normal type of this class of materials, it is added:—

	Sheppy.	Harwich.	Yorkshire.
Carbonate of Lime . . . per cent.	55	49	62
Silicate of alumina . . . „	38	47	34
Oxide of iron and other substances „	7	3	4

The so-called Medina cement approaches very closely in its composition to the Yorkshire, or Atkinson's cement.

It is usually considered that the lighter the specific gravity of a natural cement may be, the better will be its useful properties; and that the finer the powder into which it is ground, the more regular will be its action. Upon the first addition of water, a certain amount of heat will be evolved from the portion which enters into chemical combination with the cement, and the operation of setting should not be allowed to commence until the whole of this heat is given off. The rate of setting will depend very much upon the quantity, and the quality, of the water used, and upon the proportions of sand mixed with the cement; when pure cement, treated in the best manner, is used, the setting will, in fact, take place within about six minutes; whereas if two proportions of sand be used to one of cement, and much water be introduced, the time of setting may extend to as much as one hour twenty minutes; and if the mortar so made be immersed in sea water, the time of setting may even reach twenty-four hours. It is considered that the average resistance of pure natural cements to crushing weights, is equal to about 746 lbs. per superficial inch, to an effort of traction, their powers of resistance are only equal to 54 lbs. per superficial inch.

Artificial cements are made either by mixing with the feebly hydraulic limes natural substances, such as pozzuolano, or trass, which are able to impart to them the power of setting under water; or by the addition of broken tiles, or underburnt clay, to those limes. Of late years, however, both these systems of making artificial cements have been abandoned in England, and the use of what is called (rather absurdly) the Portland cements has been substituted for them. These Portland cements are obtained by burning together, under the influence of intense heat, certain proportions of a soft and pure carbonate of lime (such as the middle chalk around London) and the fine alluvial mud of our English rivers; the proportions of clay and carbonate of lime being about, or rather less than, those of the Yorkshire cement stones.

The principal difference between the natural and the artificial calcareous cements, consists, it is to be observed, principally in the degree of heat to which they are exposed; and it would appear that the combinations effected under these circumstances have a very marked influence upon the ultimate powers of resistance the cements attain. The Portland cements, indeed, do not set so rapidly as do the Roman cements, but when the setting has once commenced, the strength of the resulting material continues to increase indefinitely; whereas the Roman cements soon attain a degree of strength which they do not subsequently exceed—even if they retain it. The resistance of Portland cement, of the best description, to efforts of compression, is estimated to be equal to 2074 lbs per superficial inch; and to efforts of traction to 146 lbs. per superficial inch. The time of setting is at least from three to four times longer than that of the natural cements.

In works of internal decoration the gypseous cements are largely used; and the rapidity with which they pass through the chemical changes effected during their application, gives them a decided superiority over the ordinary plasters. The materials of this description most generally used are the Keene's, or the Parian cements; the former of which is obtained by recalcining a dehydrised sulphate of lime, which has been subsequently saturated with a solution of alum and water; the latter is obtained by recalcining, in the same way, a plaster saturated with a solution of borax. Of the two materials, the Parian cement is by far the better.

The oil cements, or the mastics, were formerly much used in London, but they have so signally failed that it may suffice to say, that they are composed of a mixture of lime, powdered tiles, litharge, and oil; they produce a good face for ornamental work in sheltered positions, but they do not resist the London atmosphere, nor have they any valuable powers of resistance as cementitious materials.

Having thus described the most important among the cements used by civil engineers and builders, we proceed to notice briefly several compositions, intended chiefly to cause the adhesion of surfaces in many departments of the manufacturing arts. Several are described in later articles. [GLUE; LUTES; MASTICH; SOLDER.] Referring to those articles for information on the special subjects to which they relate, we will confine our attention to adhesive compositions of a mis-

cellaneous kind—such, for example, as are intended for temporary use, for mending articles which have been broken, or for replacing damaged parts.

Temporary cements are such as are used for holding articles firmly during the operations of the workmen, and which are easily removed when there is no further occasion for them. Thus, in fixing glass plates to blocks to be ground for optical purposes, the following is recommended as a useful cement: melt together four ounces of resin, a quarter of an ounce of bees'-wax, and add four ounces of whitening, previously made red hot, while yet warm. This cement will also answer the purpose of joining metallic plates to be turned in a lathe.

Chasers of gold and silver articles support and hold their work by a cement formed of pitch, resin, and a very small quantity of tallow melted together, and thickened by stirring in brick-dust; this cement may also be used for fixing small steel articles on the blocks intended to hold them for polishing. In winter more tallow is necessary than in summer. Shell-lac is also usefully employed for holding metals, glass, or precious stones, while cutting, turning, or grinding them; the metal or other substance should be warmed to melt the cement.

Permanent cements are prepared with various ingredients. Thus, supposing ornaments of Derbyshire spar or other similar substances to be injured by being chipped or broken, the parts may be restored by using a cement composed of seven or eight parts of resin and one of bees'-wax, with a little plaster of Paris, melted together. The pieces of spar must be heated until they are hot enough to melt the cement, and this being interposed, the parts are to be pressed together; when the cement is used to fill up the place of any small pieces that may have been lost, the quantity of plaster of Paris must be increased. Sulphur also, placed between the heated surfaces of broken stones, makes a good cement; and when little holes are to be filled up, some of the hardened stone should be mixed with the melted sulphur.

Jewellers, in setting precious stones which have been accidentally broken, cement the pieces together by applying mastich between the fragments, which are sufficiently heated to melt this resin; they are then pressed together to force out the excess of mastich. A cement for glass and porcelain is made from a mixture of lime and white of egg; and the same purpose is also answered by dissolving gum arabic in a little water, adding proof spirit and gum ammoniac.

Another cement for the same purpose is prepared by mixing three parts of isinglass soaked in warm water for half an hour; pour off the water and add one part of gum ammoniac, previously dissolved in proof spirit of wine; the mixture is to be heated until a drop of the composition becomes instantly stiff by cooling. When used to join broken porcelain or glass, the pieces should be first warmed; the fluid cement should be laid on with a brush, and the pieces pressed together; or, if necessary, tied to prevent their separation.

Japanese cement is said to be prepared by mixing rice-flour intimately with cold water, and then boiling the mixture; it is white, and dries nearly transparent. It is therefore very useful in the manufacture of curious paper articles, which require layers of paper to be cemented together. When made with a smaller quantity of water, models, busts, &c., may be formed of it.

A cement used for engineering works is prepared as follows: take two ounces of sal ammoniac, one ounce of flowers of sulphur, and sixteen ounces of cast-iron filings or borings. Mix them well by rubbing in a mortar, and keep the mixture dry: when it is wanted, take one part of this powder and twenty parts of clean iron borings or filings, and mix them thoroughly by grinding in a mortar; add enough water to give a proper consistence, and apply it to the joints. In this case chemical action goes on, sulphuret of iron being slowly formed, and a great degree of hardness is acquired.

In joining the flanches of iron cylinders, a mixture of litharge, red and white lead, boiled in linseed oil, is made use of. It may be applied spread on flannel or linen, placed between the joints before they are screwed together. The proportions of the ingredient are not important, provided too much oil be not used, so as to make the composition too thin. This cement answers for the joints of stone cisterns intended to hold water.

Coppersmiths lay over the rivets and edges of the sheets of copper in large boilers a mixture of quicklime and ox's blood. It must be applied fresh made, as it soon hardens; this cement is both cheap and effectual.

According to Mr. Singer, a good cement for electrical apparatus is prepared by melting together about five pounds of resin, one pound of bee's-wax, one of red ochre, and about two ounces of plaster of Paris.

What is called 'mouth glue,' and the adhesive composition at the back of postage-stamps and luggage-labels, are useful examples of a very speedy mode of cementing by moistening the surfaces on which the adhesive composition has been spread.

CEMETERY. [INTERMENT.]

CENSER, a vessel used for burning and wafting incense, from the French *encenser*, to perfume. It was called by the Greeks *Thymiaterion* (*θυμιατήριον*), and by the Romans *Thuribulum*, and was often made of gold or silver, and enriched with gems. The censers of the ancient Hebrews were a sort of chafing-dishes, or perfuming-pans, with or without handles, which the high-priest placed on the altar of incense, or carried into the sanctuary. St. John in the Revelations (v. 8), speaking of the censers held by the four-and-twenty elders, calls them

dishes only, or golden cups full of incense; such, probably as occur upon the reverses of the coins of Simon Maccabæus. Josephus speaks of a very large number of golden censers, made by Solomon for the Temple at Jerusalem. A censor with smoke issuing from it occurs upon some of the Hebrew silver coins of modern time. Censers are still used in the Roman Catholic worship, and are usually carried by acolytes. Censers or thuribles of mediæval date are often of very rich workmanship. They often occur of the 12th century and later in the form of a church. According to Theophilus the monk, thuribles were directed to be made in the form of a temple, but the temple form never appears to have been general.

CENSOR, the name of one of the superior magistrates in ancient Rome. There were two officers of this name, *censores*. They were first created A.U.C. 311 (B.C. 443), when the consuls were too much occupied with the concerns of war to allow of their making the census themselves. (Liv. iv. 8.) At first they were exclusively of the patrician order; the first plebeian who was elected was C. Marcius Rutilus, A.U.C. 403 (B.C. 351.) (Liv. vii. 22.) In 622 (B.C. 132) both were plebeians, L. Pompeius and L. Metellus. (Liv. 'Epit.' lix.) Originally, according to Niebuhr, vol. ii. 394, the censors were chosen by the patrician body, the curies (*curiæ*), and their election was confirmed by the centuries; in later times they were chosen by the centuries, and their election was confirmed by the curies; the centuries also passed the law by which the censors formally received their powers; thus the centuries voted twice over.

At first the censorship lasted for five years, but a law was afterwards passed abridging its duration to a year and a half. (Liv. iv. 24.) The office underwent many changes in the time of the emperors. Julius Cæsar acted for several years as *Præfectus Morum*, and subsequently was made censor for life. Augustus performed the functions of the office, but refused the title. Under Tiberius the censorship was abolished (Tacit. 'Ann.' ii. 33), and no attempt at its restoration was successful.

When one of the censors died, it was not the custom to choose another in his place; it is true this was once done, but in the same lustre Rome was taken. Superstitious reasons prevented a repetition of the experiment. Accordingly, on the death of one, the remaining colleague resigned, and two fresh censors were chosen. (Liv. v. 31; vi. 27.) Their duties originally were the administration of the public property and revenues, registering the citizens according to their different orders, and keeping the land-tax rolls. In itself the office was insignificant, but in the hands of influential persons it was likely to become powerful. (Liv. iv. 8.) The rank of the citizens and the valuation of taxable property were at the disposal of the censors. The power thus entrusted to them naturally grew with exercise, till in later times it became despotic. No order in the state was exempt from their control. They could exclude a senator from the senate-house, deprive an eques of his horse and rank, or remove a plebeian from his tribe. To inspect the manners and guard the morals of the people was a somewhat indefinite commission; and, though parental indulgence and petty family squabbles seem unsuitable subjects for the interference of the state, it is often difficult to determine whether the actions of the censors were in reality over-rigorous, or only conscientiously strict. (Nieb. vol. ii. p. 397.) If a man let his field run wild, the censors considered him unworthy of his order, and forthwith removed him from his tribe. But notwithstanding the immense power which they thus exerted over the rights and privileges of a Roman citizen, no instance is found of their having deprived him of his franchise. When it is said (Liv. viii. 17) that they added new tribes to the old ones, it is not implied that in these cases they acted on their own independent authority, but only that *they*, and *no other* magistrate, proposed to the people the law which effected the addition. (Nieb. vol. ii. p. 399.) They could no more give the freedom of the city to foreigners, than they could take it from citizens.

They could go farther than the rank and character of the citizen in their punishments. Whenever they thought a man deserved it, they could brand him with public disgrace—a stigma corresponding to *atimia* at Athens. But of this censorian atimy or ignominy at Rome, there were two kinds. It was inflicted by the censors, sometimes in their own name and authority, and sometimes in the name of a court of law, whose judgment they only executed. The merely censorian brand did not disqualify a man for the functions of a citizen, or even for preferment to posts of honour; an appeal always lay, and was sometimes actually made from their sentence to the people; the censors themselves even went so far as to stigmatise one another. (Liv. xxix. 37.) Cicero mentions ('Pro Cluent.' 42, 119) an instance of one man, C. Geta, who had been ejected from the senate by L. Metellus and Cn. Domitius, and was afterwards created censor, so that he who had himself fallen under the censorian rebuke, actually presided over the morals of the Roman people, and of those very men who had reprehended him. This was never the case when the censors inflicted the sentence for a judicial court. That sentence, once passed, they were unable to revoke. The administration of the public revenues was a part of the business of the censors, and we find them not only establishing tolls and excise duties in subject towns, but actually fixing the price at which salt should be sold in Rome itself. They let to farm the customs and the contracts for public works. They superintended the roads, and took care of the public books and documents. Cases of

marriage and betrothing came under their inspection. (Varro, 'de L.L.' vi. 71, ed. Müller.) Their acts were registered in public documents; and the purity which was required in those who filled the office is indicated by the circumstance, that those documents were preserved in the temple of the Nymphs. (Cic. 'pro Mil.' 27.) The writing was probably performed by public slaves in the service of the censors. (Liv. xliii. 16; Nieb. vol. ii. p. 404.)

The censors might be tried when they acted improperly (Liv. xxiv. 43), and even be led to prison (ix. 34), or thrown from the Tarpeian rock. (Liv. 'Epit.' lix.)

There were also censors in many of the municipia, and in the provinces. (Cic. in 'Verr.' ii. 53.)

In modern times an officer has been appointed in different countries under the title of *censor*, whose business has been to examine all books previous to their publication, and to see that they contain nothing which the government considers immoral or heretical. In England, before the revolution, there was an officer of this kind. [CENSORSHIP OF THE PRESS.]

CENSORSHIP OF THE PRESS, a regulation which has prevailed in most countries of Europe, and still prevails in many, according to which printed books, pamphlets, and newspapers, are examined by persons appointed for the purpose, who are empowered to prevent publication if they see sufficient reason.

There are different modes of censorship; the universal previous censorship, by which all manuscripts must be examined and approved of before they are sent to press; the indirect censorship, which examines works after they have been printed, and, if it finds anything objectionable, stops their sale and confiscates the edition, and marks out the author or editor for prosecution; the optional censorship, which allows an author to tender his manuscript for examination, in order to be discharged from all responsibility afterwards; and lastly, by a distinction which has been very commonly made between newspapers or pamphlets and works of a greater bulk, the censorship of the journals, which exists even in countries where larger works are free from this superintendence. All these forms of censorship imply an establishment of censors, examiners, inspectors, or licensors, as they have been variously called, appointed for the purpose, a provision quite distinct from the laws which define the various offences which a man may be guilty of by publication. These are repressive or penal laws, whilst the censorship, and especially the previous censorship, is essentially a preventive regulation.

The censorship may be said to be coeval with printing. In more ancient times, those writings which were obnoxious to the prevailing political or religious systems, if they fell under the eyes of men in authority, were condemned to be destroyed. Thus, all the copies of the works of Protagoras which could be found in Athens were publicly burnt by sentence of the Areopagus, because the author expressed doubts concerning the existence of the gods. Personal defamation and satire were also forbidden. Nævius at Rome was banished, some say put in prison, for having, in his plays, cast reflections on several patricians. Augustus ordered the satirical works of Labienus to be burnt, and Ovid's alleged or probable cause of exile was his amatory poetry. The senate under Tiberius condemned a work to be burnt, in which Cassius was styled the last of the Romans. Diocletian ordered the sacred books of the Christians to be burnt, and afterwards Constantine condemned the works of Arius to the flames. But even under the despotism of the Roman emperors, proof of the truth of the allegations secured an exemption from punishment. (Tacitus, 'Annal.' i. 72.) All these, however, were penal enactments, independent of any censorship. The councils of the Church condemned books which they judged to be heretical, and warned the faithful against reading them. Afterwards the popes began to condemn certain works, and prohibit the reading of them. In the time of Huss and Wycliffe, Pope Martin V. excommunicated those who read prohibited books. The introduction of printing having awakened the fears of the ecclesiastical authorities, several bishops ordered books to be examined by censors. One of the earliest instances of this is that quoted by Johann Beckmann, in his 'Book of Inventions,' of Berchthold, Archbishop of Mainz, who in the year 1486 issued a mandate, in which, after censuring the practice of translating the sacred writings from the Latin into the vulgar German, a language, he says, too rude and too poor to express the exact meaning of the inspired text, he adverts to the translations of the books of the canon and civil law, works, as the archbishop says, so difficult as to require the whole life of man to be understood, a difficulty which is now increased by the incompetence of the translator, which renders obscurity still more obscure. His grace therefore, setting a full value on the art of printing, "which had its cradle in this illustrious city of Mainz," and wishing to preserve its honour by preventing it being abused, forbids all persons subject to his authority, clerical and lay, of whatever rank, order, and profession, to print the translation of any work from the Greek, Latin, or any other language, into German, concerning any art, science, or information whatever, publicly or privately, unless such translation be read and approved of before being printed, and, when printed, before being published, and furnished with the written testimony of one of the doctors and professors of the University of Mainz, named by the archbishop, one for theology, one for law, one for medicine, and one for the arts. All who violated this order were to lose the book, pay a fine of one hundred gold florins to the Electoral

Chamber, and be excommunicated. There was however no general system of censorship in the 15th century, which was an age of freedom for printing; and it is a curious fact that the learned scholar Merula, in a letter to his friend Poliziano, dated 1480, expresses a wish that a previous censorship should be established over all books, such as Plato recommends for his republic, "for," says Merula, "we are now quite overcome by a quantity of bad or insignificant books."

In 1501, Pope Alexander VI. (Borgia) issued a bull, in which he strictly forbids all printers, their servants, and all who exercise the art of printing in any manner in the above provinces, to print hereafter any books, treatises, or writings, without previously applying to the respective archbishop, or his vicar and officials, or whomsoever they may appoint for the purpose, and obtaining their licence free of all expense, under pain of excommunication, besides a pecuniary fine at the discretion of the respective archbishops, bishops, or vicars-general. The bull provides for the books already printed and published, which are to be examined by the same authorities, and those containing any thing to the prejudice of the Catholic faith are to be burnt.

At last, in 1515, the Council of the Lateran decreed that in future no books should be printed in any town or diocese unless they were previously inspected and carefully examined, if at Rome by the vicar and the master of the sacred palace, and in the other dioceses by the bishop or those by him appointed, and by the inquisitor of that diocese or those by him appointed, and countersigned by their own hands gratis and without delay. Any book not so examined and countersigned was to be burnt, and the author or editor excommunicated.

Here, then, was the origin of the principle of a general censorship of the press, which has been ever since maintained by the Church of Rome in all countries where it had power to enforce it. The bishops were the censors in their respective dioceses; but the tribunal of the Inquisition, wherever the Inquisition was established, were the censors; they examined the MS. of every work previous to its being printed, and granted or refused an "Imprimatur," or licence at their pleasure. In countries where the inquisition was not established, such as France, England, and Germany, the bishops acted as censors and licensors of books, which they examined or caused to be examined previous to printing, as to all matters concerning religion or morality.

The censorship continued for a long time to belong to the ecclesiastical power; and even afterwards, when the civil power in various countries began to appoint royal censors to examine all kinds of works, the episcopal approbation was still required for all books which treated of religion or church discipline.

The Reformation greatly modified the censorship and reduced its powers, without however abolishing it: the power passed into other hands. In England the practice seems to have been to appoint licensors for the various branches of learning; but the bishops monopolised the principal part of the licensing power, as we find at the beginning of the reign of Charles I., in a petition of the printers and booksellers to the House of Commons complaints against Bishop Laud that the licensing of books being wholly confined to him and his chaplains, he allowed books which favoured Popery to be published, but refused licensing those which were written against it. The system of previous licensing, however, did not always secure an author from subsequent responsibility. Thus Prynne's 'Histriomastix' was condemned, in 1633, to be burnt by the hangman, for being a satire on the royal family and government, and the author to have his ears cut off, and to be imprisoned and heavily fined, although the book had actually been licensed, but it was alleged on the trial that the licenser had not read the whole of the work.

A decree of the Star Chamber concerning printing and licensing, dated 11th of July, 1637, was issued, in order to establish a general system on the subject. The preamble refers to former decrees and ordinances for the better government and regulating of printers and printing, and particularly to an order of the 23rd of June, in the 28th year of Elizabeth. It then goes on to provide that all books concerning the common laws of the realm shall have the special approbation of the Lords Chief Justices and Lord Chief Baron for the time being, or one or more of them, or by their appointment; that all books of history or any other book of state affairs shall be licensed by the principal secretaries of state, or one of them, or by their appointment; and that all books concerning heraldry, titles of honour and arms, or otherwise concerning the office of earl marshal, shall be licensed by the earl marshal, or by his appointment; and that all other books whether of divinity, physics, philosophy, poetry, or whatsoever, shall be allowed by the Lord Archbishop of Canterbury or Bishop of London for the time being, or by the chancellors or vice-chancellors of either of the universities of this realm, for such books that are to be printed within the limits of the universities respectively, not meddling either with books of the common law or matters of state. All books coming from beyond the seas were to be reported by the merchant or consignee to the Archbishop of Canterbury or the Bishop of London, and to remain in custody of the custom-house officers until the archbishop or bishop sent one of his chaplains or some other learned man, to be present with the master and wardens of the Company of Stationers or one of them, at the opening of the bale or package, for the purpose of examining the books therein contained. And if any seditious, schismatical, or offensive book was found among them, it was to be

brought forthwith to the Archbishop of Canterbury or the Bishop of London, or to the High Commission Office, to be dealt with accordingly. All books, ballads, charts, and portraits were to bear the name of the printer or engraver as well as of the author or maker. All printers were to take out a licence. Their number was fixed and their names were published.

The war between Charles I. and the Parliament, and the abolition of the royal authority, did not affect the censorship, and the Long Parliament in the plenitude of its power maintained the practice just as the Star Chamber had done.

In March, 1642, an order of the Commons House of Parliament appointed by name certain stationers of London to search for any lying pamphlets scandalous to his majesty, or the proceedings of both or either House of Parliament, demolish and take away the printing-presses, and apprehend the printers or sellers.

In June, 1643, was issued an order of the Lords and Commons assembled in parliament for the regulating of printing, and for suppressing the great late abuses and frequent disorders in printing many false, scandalous, seditious, libellous, and unlicensed pamphlets, to the great defamation of religion and government. It enacts that no book, pamphlet, paper, nor part of any such book, pamphlet, or paper, shall from henceforth be printed, bound, stitched or put to sale by any person or persons whatsoever unless the same be first approved of and licensed under the hands of such person or persons as both or either of the Houses of Parliament shall appoint for the licensing of the same, and entered into the register-book of the Company of Stationers, according to the ancient custom. And further on it authorises or requires the master and wardens of the said company, the gentleman usher of the House of Peers, the sergeant of the Commons' House and their deputies, together with the persons formerly appointed by the committee of the House of Commons for examination, to make from time to time diligent search in all places where they shall think meet, for all unlicensed printing-presses, and all presses any way employed in the printing of scandalous or unlicensed papers, pamphlets, books, &c., and to seize, deface, and destroy the same in the Common Hall of the said company.

It was in consequence of this order that John Milton wrote his 'Areopagitica: a Speech for the Liberty of unlicensed Printing,' addressed to the Parliament of England, in which he shows that the system of licensing originated with the Papal Inquisition, and that it ought not to be adopted by a Protestant community: he exhibits its uselessness and injustice, and observes that the order of parliament is only a revival of the former order of the Star Chamber. Milton's disquisition is a piece of close reasoning and eloquently written; but it had no effect upon parliament, which continued to sanction the restraints upon the press, even after the abolition of royalty.

The parliament of 1654 appointed a committee to watch all blasphemous publications, on whose reports several books, religious or controversial, were ordered to be burnt.

The parliament of 1656 appointed a committee to consider the way of suppressing private presses and regulating the press, and suppressing and preventing scandalous books and pamphlets. The Protector Cromwell enforced these restraints, in order to prevent the agitation of political questions. In October, 1653, the council at Whitehall ordered that no person shall presume to publish in print any matter of public news or intelligence, without leave and approbation of the secretary of state. There appeared also an order of the protector and council against printing unlicensed and scandalous books and pamphlets, and for regulating printing. Cromwell however was disposed in general to rescue the victims of religious intolerance from the hands of their persecutors, the Independents and Presbyterians.

After the Restoration, Roger Lestrangle was appointed licenser of printing. He wrote in 1663, 'Considerations and Proposals in order to the Regulation of the Press.' Lestrangle seems to have retained his office till the revolution of 1688, when he was succeeded by Fraser, and he by Edmund Bohun.

The Act passed under Charles II., in 1662, which was, with few alterations, a copy of the Parliamentary ordinances concerning the licensing of printing, expired in 1679, but was revived by statute 1 Jac. II. c. 17, and continued till 1692. It was then continued for two years longer by statute 4 Will. & Mary, c. 24, and it expired in 1694, when the licensing system finally ceased in England. But the question of its revival was repeatedly agitated in parliament, as we see by a paper dated 1704, entitled 'Reasons against restraining the Press,' which deprecates the intention of reviving the licensing system; and by a much later and bolder pamphlet, dated 1729, styled, 'Letter to a Great Man concerning the Liberty of the Press.'

A relic of the old licensing system yet remains in the power of the Lord Chamberlain, or his deputy, the licenser of plays, to forbid the performance of any drama on the stage; but no attempt has ever been made to extend this power so far as to forbid the printing. Though, however, the power is very seldom exercised, it is still retained, and as recently as the spring of 1859, the representation of a drama ('Jack Sheppard'), which had passed uncensored for many years, was forbidden, and the command was unhesitatingly obeyed.

Under the old French monarchy, all works previous to being printed were to be examined by the royal censors, and if approved were signed with their permission. The French censorship was originally in the

hands of the bishops, for all matters concerning religion and ecclesiastical discipline. By degrees the bishops delegated this power to the faculty of theology, and the Parliament of Paris sanctioned the practice. In 1624, the faculty being divided into parties on some matters of controversy, Dr. Duval, the leader of one of the parties, obtained the king's letters patent for himself and three of his colleagues, by which they obtained the exclusive authority of approving of all books concerning religion and church discipline. The faculty remonstrated against this innovation, but the king maintained his appointment. After Duval's death, the faculty resumed its old powers; but in 1653, the controversy concerning grace having given birth to a multitude of polemical works, concerning which the faculty itself was divided in opinion, the chancellor Seguier took from it the censorship; and he created four censors, with an annual stipend, to examine all works without distinction. Before that time it appears that works unconnected with religion were examined by the *Maitres des Requêtes*. But from 1653, the appointment of the censors rested with the chancellor. They were styled Royal Censors, and their number was gradually increased. They were distributed into seven classes, according to the nature of the works which they had to examine; namely, theology, jurisprudence, natural history and medicine, surgery, mathematics, history and belles lettres (which class had the greatest number of censors attached to it), and lastly, geography, navigation, travels, and engravings. No work could be printed or sold unless it was previously examined and approved by one of the Royal Censors. The lieutenant of police had under him a censor who examined all dramatic works before they could be performed.

At the Revolution the censorship was abolished. The republican constitutions which were proclaimed in succession, acknowledged the principle of the liberty of the press; but amidst the struggle of parties, that principle was often overlooked, and journals and other works obnoxious to the ruling faction of the day were seized, and the authors or editors imprisoned and transported. Throughout the whole period of the so-called French republic, liberty existed in name, but not in reality. After the revolution of Brumaire, when Bonaparte was proclaimed First Consul of the French Republic, with powers more extensive than those of most kings, the question of the press attracted his early attention. No censorship was established by the consular constitution, but the newspaper press was left at the mercy of the executive. By a decree of the 27th Nivose, 1800, the number of newspapers at Paris was fixed, and the editors were forbidden to insert any article "derogatory of the respect due to the institutions of the country, the sovereignty of the people, and the glory of the French armies," or offensive to the governments and nations which were the friends and allies of France, even if such articles should be extracted from foreign journals, under pain of immediate suppression. The 'Moniteur' was announced to be the only official journal. Under Napoleon there was a committee of the Senate appointed to "protect the liberty of the press;" but the protection consisted in preventing either the printing or the publishing of anything contrary to the will of the authorities; although in 1806 it was declared that there existed no censorship in France,—that any French citizen could publish any book that he thought proper, being responsible for its contents before the tribunals, if charged with anything derogatory of the power of the emperor and the interests of the country.

In Napoleon's kingdom of Italy the censorship was likewise declared to be abolished, but on the day of the publication of a work two copies were to be deposited at the office of the Minister of the Interior. A commission, styled likewise "of the liberty of the press," examined the book and made its report to the minister, who, if he saw reason, stopped the sale of the work, and ordered the author or printer to be arrested and tried. Those who wished to avoid such risks were allowed to lay their manuscripts before the commission, which returned it with such corrections or suppressions as it thought advisable. This was called the facultative or optional censorship.

In 1809–10 there were discussions in the council of state respecting the laws of the press, which resulted in the decree of February, 1810, appointing a director-general of the press, with auditors, inspectors, and censors, under the control of the Minister of the Interior. The number of printers was to be fixed in every department; sixty was the number fixed for Paris. Printers, as well as booksellers, were to take licences and swear fidelity to their country and the emperor. Printers were forbidden to print anything derogatory of the duties of subjects towards their sovereign, or of the interests of the state. Parties offending were to be brought before the courts, and punished according to the Penal Code; besides which, the Minister of the Interior had the right of depriving the printer of his licence. Before setting up a work, the printer was to transmit the title of it, with the name of the author, if known, to the director-general, and likewise to the prefect of the department, declaring his intention to publish the work. The director-general could, if he chose, ask for the manuscript, and send it to one of the censors for examination. After the censor had made his report, the director would point out such alterations or suppressions in the text as he thought proper, and which became obligatory upon the author or printer, who however had the right of appealing to the Minister of the Interior, who forwarded the manuscript to another censor, who made his report to the director-general; and the director-general, assisted by other censors, decided finally upon the matter.

Authors or printers had the option of submitting their manuscripts to the examination of the censors previous to printing. But even after being examined, approved, and printed, a work could be seized and its sale stopped by the minister of police, who was however to forward it with his remarks within twenty-four hours to the council of state, which judged finally upon it. A well-known instance of this occurred with regard to Madame de Staël's book on Germany, which was seized after having been examined and printed, and the whole edition was destroyed. "Your book is not French, and we are not reduced to seek for models among the nations which you admire," was the minister of police's (Savary) reply to Madame de Staël's remonstrances on the subject.

Books printed abroad could not be imported into France without permission from the director-general.

The police had the censorship of dramatic works intended for the stage. Only one newspaper was allowed in each department, with the exception of Paris, subject to the approbation of the respective prefects. Such was the condition of the press in France during the latter years of Napoleon's empire.

At the first restoration of the Bourbons, in 1814, an article of the charter of Louis XVIII., acknowledged that "Frenchmen had the right of publishing their opinions by means of the press, conformably however to the laws enacted for the repression of any abuse of the liberty of the press." Soon after, the Abbé de Montesquieu, Minister of the Interior, procured the passing of a law by the chambers, by which all works consisting of less than twenty sheets were subjected to a previous censorship. A council of twenty censors was appointed. The office of director-general of the press was retained. Every printer was obliged to give notice of each work that he intended to print, and to deposit two copies of it, when printed, at the director's office, before he published the work.

When Napoleon returned from Elba, in 1815, he did not enforce the previous censorship, because, said he, they had published whatever they pleased against him under the Bourbons, and the matter was now exhausted. The other regulations however concerning printing and publishing were maintained, and the press and the emperor were often at variance during the hundred days. The previous censorship was temporarily re-established and abolished again under the second restoration of Louis XVIII. After Charles X. came to the throne, he abolished the previous censorship altogether, and by so doing he gained a momentary popularity with the Parisians. But the first of the ordinances, signed the 25th of July, 1830, suspended the liberty of the periodical press; no journal was to be henceforth published without a special authorisation of the government, which was to be renewed every three months. All pamphlets or works under twenty sheets of letter-press, were made subject to the same authorisation. The ordinances however were resisted, and the revolution of July was the result. The revised charter which was afterwards promulgated, 'Charte de 1830,' in its seventh article says, "Frenchmen have the right of publishing and printing their opinions, conformably to the laws. The censorship shall never be re-established." New laws, however, were enacted to repress the abuses of the press, among which the law of the 9th of September, 1835, embodies or refers to many of the former laws of the Empire and the Restoration. It specifies the crimes and misdemeanours committed by means of the press, and assigns the penalty to each. The proprietors of political journals are obliged to deposit a considerable sum in the treasury as a security for their good behaviour. One hundred thousand francs (four thousand pounds sterling) is the deposit required for a daily Paris newspaper, and one half the sum for a weekly paper.

Little alteration, or at most only for a short time, was made by the revolution of 1848. Under the empire the previous censorship of all works below a certain size still exists. The deposition of a large sum before the publication of a newspaper is still required; and a specially appointed minister has the power of warning a newspaper of having committed an offence, and the issuing of three such warnings is to be followed by suppression. Works after publication may be seized, and their sale forbidden; and foreign works and newspapers are liable to be seized at any time on the order of this minister.

The absolute monarchies of Europe, Russia, Austria, Prussia, and the Italian States, retain the obligatory previous censorship of the press, which is derived from the very principle of their government, that of parental authority over their subjects. In some of the Italian States (Rome and Naples, for instance) there is a double censorship; one by an ecclesiastical and the other by a political censor. But even then it happens sometimes that after a work has passed the censorship and obtained the "imprimatur," something obnoxious is discovered which had escaped the censor's penetration, and the book is seized and confiscated.

In the republics of Switzerland, the censorship existed before the organic changes which have taken place in most of the cantons since 1830. All previous censorship is abolished; but the laws in some of the cantons are very restrictive of the liberty of the press, and especially of the newspaper press, on matters of religion. Generally speaking, the press is freest in the Protestant cantons.

The liberty of the German press varied according to the spirit of the different governments. As early as 1570, by a decree of the empire, printing-presses were only permitted in towns which were the

residences of sovereign princes; and every printer was required, if called upon, to take an oath to print only what was just, honourable, and altogether fitting. During the Thirty Years' War an universal freedom prevailed; but on the conclusion of the Peace of Westphalia, the "massacre of the press" was again a matter of complaint. In Saxony, Prussia, Hanover, and the Free Towns considerable freedom was allowed, while in Austria and Bavaria the regulations were very stringent; and in all it depended on the government, and was nowhere recognised as an inalienable right of the people. During the war which ended in the downfall of Napoleon, reforms of all kinds were promised to the people, and especially freedom of the press. This promise was very imperfectly fulfilled, but the censorship was removed in several of the minor states. The political agitation of Europe after the downfall of Napoleon, however, caused the German rulers to hold a congress at Karlsbad in 1819, by which the German periodical press was enslaved by the decision that all books or other printed publications under twenty sheets should be subjected to a censorship. The spirit which directed this censorship was most arbitrary and harsh, and led to collisions of the most dangerous kind between the representative bodies of the state and the rulers. Nor was the liberty of the press for books above twenty sheets respected, and political authors especially experienced many persecutions, while strangely enough religious matters might be treated with perfect freedom.

After the French revolution of 1830, the people of Germany rose in arms, demanding constitutional rights, and above all a free press, and the rulers were in some states compelled to grant their claims. Again, however, when the people had been quieted, measures were taken to revoke all these privileges. On June 28, 1832, the Diet resolved that care should be taken to compel the editors of newspapers and other political productions to keep within proper limits in publishing the debates of the representative bodies; and the Diet of 1836 declared that editors of newspapers and political writers should publish no account of such debates, except those published in the government papers, or extracts from them. Since that time there has been a visible reaction against the freedom of the press, though the censorship is much more severe against political and historical publications than against other works. During the revolutionary disturbances in Germany in 1848, the first demand, in almost every country where a rising took place, was for an emancipation of the press from its restrictions. It was uniformly granted, and it was voted by the Bundesversammlung in the sitting of March 3. Even Austria agreed to it, with a promise that the censure should not be again established; and throughout Germany the only requisition was that the printers' and publishers' names should be always printed, and that they should be answerable for infractions of law. But as early as March, 1849, Austria set the example of abrogating these privileges; the other states lost no time in following it, and by the end of 1850 the old system of censorship and supervision had been thoroughly restored. In Austria the newspaper press is under the direct control of the government; and in Prussia a large deposit is required before a newspaper can be published, and the minister has the power of appointing a working editor.

By the Spanish constitution of 1837, "all Spaniards may print and publish their thoughts freely, without previous censorship, but subject to the laws. The determination of offences by means of the press belongs exclusively to juries empanelled for that purpose;" but this regulation, always imperfectly observed, was superseded by a law passed in 1850, and though by it no previous censorship was established, books and newspapers are liable to be seized if they contain anything offensive to the government.

The constitution of Portugal establishes no previous censorship, but refers to the laws for repressing the abuses of the press.

By the constitution of the kingdom of Greece of 1827, "the Hellenes have the right of publishing freely their thoughts by means of the press, abstaining however,—1, from attacking the principles of the Christian religion; 2, offending decency and morality; 3, indulging in personal insult and calumny."

The Swedish constitution of 1809, promulgated under King Charles XIII., enacts that the states of the kingdom in every new Diet shall appoint a committee of six members, well informed persons, among whom must be two jurists, for the purpose of maintaining the liberty of the press. The committee will examine all MSS. which shall be laid before it by any author or bookseller; and if the committee declares that the work is fit to be printed, the author and publisher are thenceforth discharged from all further responsibility. The Chancellor of Justice of the State is by right President of the Committee. But this is a voluntary, and not an obligatory, previous censorship. Persons guilty of libel and other offences by means of the press are tried by a jury. By a law enacted by the Diet in 1812, a newspaper which insults or defames a foreign government friendly to Sweden, is liable to be suppressed by order of the chancellor, without any other formality. This has occurred repeatedly, but then the paper appears again the next day under a slightly altered title; for instance, the *Argus* is suppressed, but is continued under the title of *Argus II.* or *Argus III.*

The constitution of Norway proclaimed in the Storting of Eidsvold, November, 1814, enacts that no one shall be prosecuted for his printed writings, unless he wilfully and evidently manifests or encourages others to manifest disobedience to the laws, contempt for religion, morality, or the constitutional powers, or resistance to the constitu-

tional authorities, or is guilty of defamation and libel against any one, in which case he shall be fined by the tribunals.

The constitution of the Netherlands of 1815, which is still in force in the kingdom of Holland, says, Art. 227, "the press being the fittest means to spread knowledge, every one has a right to make use of it to communicate his thoughts, without needing previous permission. But all authors, printers, editors, or publishers, are answerable for those writings which attack the rights either of society or of individuals."

By Art. 18 of the constitution of Belgium, the press is declared to be free; no censorship can ever be established. Authors, editors, and printers are not required to give security. Offences committed through the press are tried by the ordinary courts.

In Denmark, an ordinance of Christian VII., dated September, 1799, on the subject of the press, abolishes the previous censorship, but imposes severe penalties on those who offend through the press; death is the penalty for any person who shall excite rebellion or provoke a fundamental change in the constitution of the monarchy. Whoever censures or defames or excites hatred or contempt against the constitution of the kingdom and the government of the king, either on general grounds or on the occasion of any particular act, shall be banished for life; and if he returns without permission, shall be sent to hard labour for life. Whoever shall censure or vilify the monarchical form of government in general shall be exiled from three to ten years. Any libel against the person and honour of the king, or any member of the royal family, shall be punished with exile. Whoever publishes a work tending to deny the existence of God, or the immortality of the soul, or to cast censure or ridicule on the fundamental dogmas of the Christian religion, is to be banished likewise. Any one who shall attack or ridicule the tenets of the other Christian communions tolerated in the kingdom, shall be punished by a short imprisonment on bread and water. The same punishment is assigned to those who shall offend public morals by their writings. Any one defaming a foreign prince friendly to Denmark, or ascribing to his government any unjust or disgraceful act, without quoting any authority, shall be sent to hard work in a house of correction for a limited period.

The constitutions of the various states composing the North American Union, admit the absolute liberty of the press. There is, of course, in each State a law of libel sufficiently strict. In the slave States there are very severe laws against interfering by the press with the great question of slavery. It has been stated that abolitionist newspapers are seized at the post-office.

The republics of Spanish America likewise acknowledge the principle of the unfettered liberty of the press, however often it may have been violated in practice amidst the never-ending factions and civil wars of those countries. The constitution of the Brazilian empire establishes the freedom of the press without any censorship; but an author is liable to punishment in such cases as are provided by law.

CENSUS, THE, at Rome, was a numbering of the people, and a valuation of their property. It was held in the Campus Martius. (Liv. iv. 22; Varro 'de R. R.' iii. 11.) Every Roman citizen was obliged, upon oath, to give in a statement of his own name and age, of the name and age of his wife, children, slaves, and freedmen, if he had any. The punishment for a false return was, that the individual's goods should be confiscated, and he himself scourged and sold for a slave. Taxation depended on the results of the census; many kinds of possessions and of actual property were excepted, while, on the other hand, some sorts of property were assessed at several times their value. Constant changes were made by successive censuses in the valuation of taxable property. Cato and Flaccus rated the taxable value of high-priced slaves at ten times the purchase-money. (Nieb., vol. ii. p. 402.)

According to the valuation of their property at the census, the citizens were divided into six classes; each class contained a number of centuries or hundreds. That a century did not always consist of a hundred men is clear, from the fact that the richest centuries were the most numerous, and consequently must individually have contained fewer persons than the centuries of the poor. The first class consisted of those whose property amounted to 100,000 *ases*, about 322*l.* 18*s.* of English money; the second class consisted of persons worth 75,000 *ases*; the fortune of the third class amounted to 50,000 *ases*; that of the fourth to 25,000; that of the fifth to 11,000; and the sixth class included all below the fifth, even those who had no estate whatever. This was naturally the fullest of the six, but was accounted only as one century. Now, as the richer classes contained far more centuries than the poorer, so much so that the first class contained more than all the rest together, and as the votes in the *Comitia Centuriata* were taken within the centuries individually, and then the voice of the majority of centuries was decisive, it is obvious that the influence of wealth was greatly preponderant in this assembly. Cicero ('De Repub.' ii. 22) assigns this as the object aimed at in the institution. The real object of the *Comitia Centuriata* was (as Niebuhr supposes) to bind the different orders of the state together in one consistent and organised body. Every one in the nation had a vote on national business; and in this assembly was laid the basis of popular liberty. In the *Comitia Centuriata* the people always appeared under arms, and each class had a particular kind of armour assigned to it.

The census was held at first by the kings, afterwards by the consuls; and, from A.U.C. 311, by the censors. After the census a sacrifice of purification was generally, but not always (Liv. iii. 22), offered. The

victims were a sow, a sheep, and a bull, which were led thrice round the army, and then slain: the sacrifice was called *Suovetaurilia*.

It does not appear that the census was held with strict regularity. It was sometimes altogether omitted. (Liv. iv. 8; Cic. 'pro Arch.' 5. 11.) The usual interval was five years; and in allusion either to the sacrifice of purification, or to the farmers paying their taxes at this time (Voss. 'Etymolog. Ling. Lat.' in *lustrum*), the interval was commonly called a lustre (*lustrum*). It is obvious that the census must have been of great use in ascertaining the actual strength and capabilities of the state.

When a person was duly entered on the books of the censors, this was taken as a proof of his citizenship, even if he were a slave, provided he had been registered with his master's consent (Cic. 'de Or.' i. 40; Ulp. i. 8); but many enactments were made to regulate and modify this legal principle. As the census was held at Rome, citizens who were in the provinces, and wished to be registered, were obliged to repair there on that occasion (Cic. 'ad Att.' i. 18, &c.); but this was sometimes evaded, and was made a matter of complaint by the censors. The census, accompanied with the ceremony of the *lustrum*, seems to have fallen into disuse after the time of Vespasian; but the numbering of the population, &c., continued till a late epoch of the empire.

As to the census in the provinces, under the empire, see Tacitus ('Ann.' i. 31, 33, &c.), and the 'Excursus' of Lipsius. See also 'Dig.' 50, Tit. 15.

The term *census* is also used in Latin authors to signify the amount of a person's estate; and hence we read of *census equester*, the estate of an eque, and *census senatorius*, the estate of a senator. (Pitisc. 'Lex. Antiq. Rom.')

CENSUS OF THE UNITED KINGDOM. The first attempt to ascertain the population of England, and to determine its increase or otherwise, by ascertaining the number of births and burials, was made at the beginning of the 18th century. This method could at best afford merely an approximation towards the truth, which can only be satisfactorily ascertained by actual enumeration; while as regards many other important questions connected with the condition of the people, it is clear that deductions drawn from registers of births and burials, if even they were perfectly accurate (and up to 1839 they were very far from being so), would give no information whatever.

The first actual and official enumeration of the people of England and Scotland was made in 1801, and subsequently in 1811, 1821, 1831, 1841, and 1851. In Ireland the earliest enumeration was made in 1813, since which time a census has been taken, as in Great Britain, in each of the years 1821, 1831, 1841, and 1851. It will be sufficient here to give first a summary of the returns of 1821, 1831, and 1841, being the earliest in which Ireland is included at the same period, and then the details of that of 1851, which embodied a number of inquiries that were unattended to in the preceding censuses.

	1821.	1831.	1841.
England	11,486,700	13,091,005	14,995,138
Wales	731,800	806,182	911,603
Scotland	2,135,300	2,365,114	2,620,184
Army, navy, and registered seamen afloat		277,017	188,453
Persons travelling on the night of June 6	Included in the above.	..	5,016
Islands in the British Seas		103,107	124,040
Great Britain	14,353,800	16,643,028	18,844,434
Ireland	6,846,949	7,767,401	8,175,124
United Kingdom	21,200,749	24,410,429	27,019,558

As we have already stated, the census of Great Britain in 1851 differed in several respects from any previous census. In some points the range of its inquiries was more minute and precise; in many others wider and more comprehensive. The words of the elaborate Report of the Registrar-General, prefixed to the volumes of Population Tables, printed by order of Parliament, will best indicate what the census of 1851 sought to accomplish:—

"At the present census it was resolved to exhibit not merely the statistics, as before, of parishes, and, more completely, of parliamentary and municipal boroughs, but also of such other large towns in England and Scotland as appeared sufficiently important for separate mention, and of all the ecclesiastical districts and new ecclesiastical parishes which, under the provisions of various Acts of Parliament, have, during the last forty years, been created in England and Wales. In addition also to the inquiry concerning the occupation, age, and birthplace, of the population, it was determined to ascertain the various relationships (such as husband, wife, son, daughter)—the civil condition (as married, unmarried, widower, or widow)—and the number of persons blind, or deaf and dumb. Further, under the impression that the fifth section of the Act would authorise such an inquiry, the design was formed of collecting statistics as to the accommodation afforded by the various churches and other places of public religious worship throughout the country, and the number of persons generally frequenting them; and also as to the existing educational establishments, and the actual number of scholars under instruction. It was, however, subsequently

considered doubtful whether, upon a rigid construction, the Census Act rendered it compulsory upon parties to afford information upon these particulars; and the inquiry was therefore pursued as a purely voluntary investigation."

For obtaining these objects, the local machinery introduced in England and Wales by the Poor Law and Registration Acts was employed, the general direction of the census, under the Secretary of State, being given to the Registrar-General. The 624 Registration Districts, into which England and Wales was divided by the Registration Act, each having a superintendent-registrar, were subdivided into 2190 subdistricts, each having a local registrar of births and deaths. These subdistricts were, for the purposes of the census, and under the supervision of the registrars and superintendent-registrars, again divided into 30,610 enumeration districts, each such district being assigned to one enumerator, who was required to complete his enumeration in *one day*. In Scotland, where no such local machinery existed, the census was taken through the agency of the sheriffs of counties and chief officers of boroughs; the working of the act being devolved chiefly on the sheriffs-substitute, "who appointed a fit person, generally the parochial schoolmaster, in each parish to divide it into convenient enumeration districts, and superintend the proceedings of the census therein." The number of enumeration districts formed throughout Scotland, in 1851, was 7873; in the islands of the British seas, 257 enumeration districts were similarly formed. Of the mode of taking the census, it will suffice to say, that blank forms were left at every house and public institution, with minute directions, in order that they might be correctly filled up with the requisite information concerning every person who abode in the house or apartment on the night of March 30, 1851. These forms were collected by the enumerators on the 31st of March; each enumerator being directed to satisfy himself, as far as possible, of the accuracy of the entries, and where inaccurate to correct them.

The vast importance of the method adopted, as a security for the accuracy and precision of the returns, will be best understood by a comparison with the method adopted in taking the Census of the United States in 1850. At that date the territory of the United States comprised an area of 3,300,000 square miles. To number the inhabitants occupying that vast space the entire staff of superior and subordinate officers employed numbered only 3276 persons,—less than one-tenth of the number employed for enumerating the population of England and Wales, a territory of 58,320 square miles, or less than a fifty-sixth of the area of the United States. It is at once evident that the American enumeration could not be made on one day, and accordingly we find that though the schedules were directed to be filled up with "reference to" a particular day, the officer did not call at the house, the inmates of which were to be numbered, till some days, weeks, or even months after the time specified; when—the careless way in which people are accustomed to treat such things being taken into account—it is scarcely possible that errors can in very numerous instances be avoided, even as regards the mere number of residents, while in respect of age and other more minute matters, the probability of error is of course largely increased.

As far as provision could be made by the strength and careful appointment of the official staff, and the strictness with which their duties were defined, the arrangements for the British Census of 1851 were in all respects admirable, and probably the returns were as accurate as under existing circumstances are attainable. It may serve to show the amount of labour which devolved on this army of enumerators (including Scotland, nearly 39,000 in number); to state that the blank-forms for England and Scotland, issued from the Census Office, amounted in all to nearly 7,000,000, the weight of them being nearly 40 tons: the "weight of the schedules, blank enumeration books, and other forms, despatched from the central office, exceeded 52 tons." The schedules, after being duly filled in, were subjected to revision by the registrars and superintendent-registrars before transmission to the Census Office, there to undergo final revision and generalisation. The enumeration of the persons on board vessels, either in harbour or at sea, was accomplished by the officers of the Customs, the Admiralty, and the Registrar of British Seamen; the enumeration of the army by the officers of the various branches, under the direction of the Commander-in-Chief. In these, as in other matters, the returns were much more minute and extensive than in any previous census; while several collateral returns were at the same time obtained, such as of the latest population of the several colonies, the number of British subjects in various foreign states, the number and rank of half-pay officers of the army, navy, and marines, of Chelsea and Greenwich pensioners, of officers employed in the civil service of the crown, &c.

The household schedules were collected on the 31st of March, and subjected, as mentioned, to revision by the registrars and superintendent registrars. "By the end of the month of May, these schedules, amounting to about 4,300,000 distinct returns, and the enumeration books 38,000 in number, were received at the central office. The result of the enumeration having been obtained from the summaries forwarded with the returns by the registrars in England and Wales, and the numbers for Scotland also ascertained, a statement of the total population and number of houses was transmitted, on the 7th of June, to the Secretary of State, and at once made public." Having mentioned the quantity of labour which devolved on the large army

of enumerators, it is only fair to add, as an evidence of its vast amount, as well as the scrupulous care with which the subsequent proceedings were conducted, that every total and summary throughout the enumerators' returns was subjected to strict and minute examination for the purpose of verification or correction; such revision alone involving "the examination and totalling of more than 20,000,000 of entries, contained on upwards of 1,250,000 pages of the enumeration books." This revision was entirely preparatory to the great work—the classification of facts.

We proceed now to the *Results* of the enumeration of the population. Stated in a single sentence, the great result of the enumeration, as given in the census of 1851, is, that Great Britain, without including the islands in the British seas, contains 13 divisions, 84 counties, 696 districts, 17,150 parishes or places, 38,483 enumeration districts, 3,648,347 houses, 20,816,351 inhabitants, and 57,372,377 acres.

The *Population* of Great Britain, including the islands in the British seas, on March 31, 1851, was 20,959,477; and the men in the army, navy, and East India Company's service, abroad, on the passage out, or round the coast, belonging to Great Britain, on the same day, was 162,490. The total population of Great Britain may therefore be set down at 21,121,967. Of these, 16,921,888 were in England; 1,005,721 in Wales; 2,888,742 in Scotland; 143,126 in the Isles of Man, Jersey, Guernsey, Alderney, and other small islands in the British seas; and 162,490 were at sea or serving abroad in the army.

The *Proportion of Males to Females* has been preserved with remarkable regularity during the half century. In 1851 the male population of Great Britain was 10,386,048, the female 10,735,919; being an excess of 349,871 females: the excess of females at home was 512,361. The proportion in 1851 was 103,369 females to every 100,000 males; in 1801 it was 103,353 females to 100,000 males. At both periods there were somewhat less than 30 males to 31 females. In 1851 there were 20 males at home to 21 females. The excess of births, however, is in the opposite direction. During the thirteen years (1839-1851) in which accurate registers of births have been kept, there have been born 3,634,235 males and 3,465,629 females, or about 105 males to every 100 females (104,865 to 100,000). The disparity in the sexes at home is greatest in Scotland—110 females to 100 males; in England and Wales it is only 104 females to 100 males. To what degree the change in the proportions and the subsequent disparity of the numbers in the two sexes is due to emigration, or to a difference in degree of the dangers and diseases to which they are respectively exposed, this is not the place to consider.

The *Increase of Population* in the last half-century nearly represents a new nation equal to that which existed in Great Britain at its commencement, and that notwithstanding the vast numbers who have "annually left the United Kingdom, settled and multiplied into millions in the United States, in the colonies of North America, of Australia, and of South Africa." The aggregate increase in the fifty years is 93·470 per cent., or at the rate of 1·329 per cent. annually. "The annual increase, however, has varied in each decennial period; it increased from 1·274 per cent. on the population in 1801-11, to 1·489 (nearly 1½) in 1811-21, when it was at the *maximum*; the annual rate of increase in 1821-31 was 1·408; in 1831-41 it fell to 1·279; and in 1841-51 to 1·186 per cent. annually. The population therefore is increasing, but the rate of increase has declined since 1811-21, when there was little emigration, and the mortality in England was lower than it has ever been before or since, down to the two last decennaries; when the public health has suffered from epidemics of influenza, cholera, and other diseases, while emigration from the United Kingdom has proceeded at an accelerated rate from 274,300 in 1821-31, to 718,000 in 1831-41, and 1,693,000 in 1841-51." During the same period the proportion of land to each person has decreased in Great Britain, from 5·4 acres in 1801, to 2·7 acres in 1851; from 4 acres to 2 acres in England and Wales.

If the rate in which the population has increased since 1801 continue to prevail uniformly, the population would double itself in Great Britain every 52½ years; in England and Wales every 51 years.

The number of *Families* in Great Britain in 1801 was 2,260,802; in 1851 it was 4,312,388; being an increase of 2,051,586. The families in England and Wales in 1801 were 1,896,723; in 1851 they were 3,712,290. In Scotland they were 364,079 in 1801, and 600,098 in 1851. The average number of families to a house in Great Britain in 1801 was 1·209, and of persons in a family, 4·645; in 1851 there were 1·182 families to a house, and 4·825 persons in a family. In Scotland in 1851 the average of persons in a family was 4·814, or nearly that of the whole island; but the average of families in a house was somewhat higher—1·621. In Glasgow the number of families to a house is 5·4; of persons to a house, 27·5; in Edinburgh the corresponding numbers are 4·2 and 20·6; in Aberdeen, 3 and 12·3; in Dundee, 3·2 and 15·7; in Perth, 2·8 and 12. In London, on the other hand, the numbers are only about the average of Scotland—1·74 and 7·7; but in some districts they are as high as 10, 11, and even 12 persons to a house. This excess in the northern cities was caused by a real difference in the habits of the people. "The towns and cities of the two northern English counties and of Scotland are built in the continental style; and the families of the middle classes, as well as the poor, live in large flats, which constitute separate tenements." The term house, in many parts of Scotland, has been usually applied to

these several flats or floors; and in every census from 1801 to 1841, "flats" in Glasgow and some other Scottish towns were returned as separate houses. In 1851 this was corrected, and the enumerators were instructed that flats and sets of chambers must not be returned as houses. The returns from Scotland, as from England, are now, therefore, made on a tolerably uniform principle, and are fairly available for comparison. The variations in the several English counties and in different districts with respect to the proportion of families to houses is considerable; but it would require far more space than we can spare to enter upon it. As a rule, in England and Wales, a house is inhabited by one family, the excess in the proportion being mainly caused by the large number of public institutions, hotels, lodging-houses, &c. The following is an analysis of the families in connection with the houses which they occupy in 14 subdistricts of England containing 35,876 inhabited houses, in which were 48,985 families (1608 of the houses having the families absent), comprising 242,164 persons, or, on an average, nearly 7 persons to a house—5 to a family. Of these houses, 26,309 contained one family; 4,789, two families; 1,523, three; 748, four; 425, five; 224, six; 118, seven; 62, eight; 32, nine; and 38, ten families and upwards. This analysis is in the Report carried out with great minuteness into a variety of particulars, but which it is impossible for us here to follow.

The number of *Houses* in Great Britain in 1851 was—inhabited, 3,670,192; uninhabited, 166,735; building, 29,194. In 1801 there were 1,882,476 inhabited, and 67,320 uninhabited; the number building was not returned. The following tables show (1) the number of principal public institutions,—of their inmates 35,516 were officers and servants; and (2) the number of persons sleeping in barges, barns, tents, and vessels.

Institutions.	No.	Persons.	Males.	Females.
Barracks	174	53,933	44,833	9,100
Workhouses	746	131,582	65,786	65,796
Prisons	257	30,959	24,593	6,366
Lunatic Asylums	149	20,004	9,753	11,251
Hospitals for the sick	118	11,647	5,893	5,754
Asylums and other charitable institutions	573	46,731	27,183	19,548
Total	2,017	295,856	178,041	117,815
Persons in barges		12,924	10,395	2,529
„ barns		9,972	7,251	2,721
„ open air in tents		8,277	4,614	3,663
„ vessels in the ports engaged in inland navigation		8,575	7,730	845
„ sea-going vessels in the ports		43,173	41,165	2,008
Total		82,921	71,155	11,766

"The enumeration of the *Houseless Population*, unsettled in families, is, however, necessarily imperfect; and the actual number must exceed the 18,249 returned, namely, 9,972 in barns, and 8,277 in the open air. It is mentioned in one instance that a tribe of gipsies struck their tents and passed into another parish in order to escape enumeration. In 1841 the number of the houseless class was 22,303; owing to the more advanced period of the year (June 7) at which the census was taken, many Irish people and labourers were then engaged in the hay harvest."

From houses and families we ascend to *Towns and Corporations*. No attempt was made to classify the smaller aggregates of houses, by defining villages, hamlets, &c.; but 17,150 places which have defined boundaries are separately returned in the Population Tables, and each of these is assumed to be a *village*, or an aggregation of families round a church or chapel; on an average these villages lie at a distance of about $2\frac{1}{2}$ miles apart, so that the inhabitants of the country around them, distributed over an area of 5 miles, lie at the average limit of $1\frac{1}{4}$ mile from the centre, or at the mean distance of six-sevenths of a mile.

"Great Britain has *eight hundred and fifteen* towns of various magnitudes, either market towns, county towns, or cities; *five hundred and eighty* in England and Wales, *two hundred and twenty-five* in Scotland, and *ten* in the Channel Islands. To 21 of the preceding 'villages' there is on an average a town, which stands in the midst of 110 square miles of country, equivalent to a square of $10\frac{1}{2}$ miles to the side, a circle having a radius of nearly 6 miles; so that the population of the country around is, on an average, about 4 miles from the centre.

"The population amounted to 10,556,288 in the 815 towns, which stand on 3,164 miles of area. An average town of 12,953 inhabitants, stands on an area of nearly 4 square miles; equivalent to a square of 2 miles to the side, a circle $1\frac{1}{10}$ th mile radius, and the population is less than three-quarters of a mile from the centre.

"The population in the rest of Great Britain was 10,403,189; consequently if, for the sake of distinction, the detached houses, the villages, and small towns without markets, are called—country; at the present time the *town* and *country* populations of Great Britain differ so little in numbers, that they may be considered equal; for, by the abstracts, 10,556,288 people live in the towns, and 10,403,189 in the country. In the towns there were 5.2 persons to an acre, in the country

5.3 acres to a person. The density in the country was 120 persons—in the towns 3,337 persons—to a square mile. . . .

"The 815 towns are grouped around 87 county towns—52 in England, 32 in Scotland, and 3 chief towns, equivalent to county towns, in the Islands of the British Seas. Each of the central county towns was surrounded on an average by eight or nine other towns, extending over an average area of 1,067 square miles, equivalent to a square of 33 miles to the side; a circle of 18 miles radius; and without allowing for the extreme distance of the Islands in the British Seas they were 35 miles apart. The population of the county towns of Great Britain, and the chief towns of the Channel Islands amounted to about 626,547 in 1801, and to 1,391,538 in 1851; in England and Wales the population of the county towns was about 473,239 in 1801, and 1,076,670 in 1851.

This equality of proportion between the town and country population of Great Britain is one of the "great facts," brought into prominent notice by the present census. The great relative increase of the population collected in the principal towns is another of the more important facts which point to a change in the habits and condition of the people. Thus, in the 61 principal towns in England and Wales, which in 1801 contained 2,163,698 inhabitants, the population had risen in 1851 to 6,254,251; in other words, in 1801, about 24 per cent. of the entire population resided in those 61 towns, while in 1851 very nearly 35 per cent. of the population resided in the same towns. In the seven principal towns in Scotland there resided in 1801, 271,486 out of the entire population of 1,608,420, or 16.8 per cent.; in 1851, 779,698 out of the entire population of 2,888,742, or 26.9 per cent.: or there occurred a relative increase in the 68 largest towns in Great Britain of upwards of 10 per cent., as compared with the increase of the entire population: that is, whereas then *two* of every *ten* persons in Great Britain resided in 68 of the principal towns, now *three* out of every *ten* persons reside in them. The increase of the population of London and the other great towns was 4,609,525, or 189 per cent. in the half-century; that of the smaller towns and the country was 5,770,996, or 71 per cent. The actual increase in some of the great towns was very remarkable. In London the population increased from 958,863 to 2,362,236, being an increase of 1,403,373, or 146 per cent.; Manchester (with Salford) from 94,786 to 401,326; Liverpool from 82,295 to 375,955, its opposite neighbour Birkenhead rising in the same time from 110 to 24,285; Birmingham from 70,670 to 232,841; Preston from 12,174 to 69,584; Bradford from 13,264 to 103,778; Plymouth from 16,040 to 52,221; Southampton from 7,913 to 35,305; Merthyr Tydfil from 10,127 to 63,080; Glasgow from 77,058 to 329,007; and other manufacturing, mining, and sea-port towns at a proportional rate. The increase in the population of the watering-places, or towns chiefly devoted to pleasure, meanwhile being at least commensurate with that of the towns devoted to business: thus Brighton increased from 7,440 in 1801, to 69,673 in 1851; and Cheltenham from 3,076 to 35,051.

Dividing the towns into classes, it appears that "the greater part (3,022,776) of the increase (5,363,650) in the six classes of towns, was in London and in the manufacturing towns; the (1) sea-ports, the (2) towns which are in mining districts, or are engaged in hardware manufactures, and (3) the county towns, severally contributed more than three-quarters of a million to the increase; the increase of the people living in watering-places was 200,164. In the latter class the rate of increase was the greatest; it was 2.561 per cent. annually. The annual rate of increase was 2.380 in the manufacturing towns, 2.336 in the mining and hardware towns, 2.191 in the sea-ports, 1.820 in London, and 1.609 in the county towns. The annual rate of increase in Great Britain during the same half-century was 1.377. The towns have increased most rapidly in which straw-plait, cotton, pottery, and iron are manufactured."

The *Density* and *Proximity* of the population are elucidated in the Report and the Summary Tables in various ways, and at considerable length: here, however, the matter must be treated briefly. The density of population, or, as a recent French authority (Baron de Prony in the 'Annuaire') has proposed to term it, the "specific population," after the analogy of "specific gravity," varies in the 624 districts of England and Wales, from 185,751 persons on a square mile in the East London district, to 18 on a square mile in that of Bellingham, Northumberland. The greatest density of population out of London is in the Liverpool district, which is 74,446, and the next Birmingham, which is 41,853 on a square mile. Manchester has 11,577, which is less than Leeds, which has 30,886; Bristol, which has 22,858; Plymouth, which has 20,441; Nottingham, which has 19,994; East Stonehouse, which has 19,913; Brighton, which has 18,088; Hull, which has 17,750; Salisbury, which has 11,907; Greenwich, which has 11,849; and Exeter, which has 11,670. The smaller density of Manchester than such towns as Salisbury and Exeter is accounted for in a great measure, by the large spaces covered by the numerous great factories and warehouses; yet the result is scarcely what would be generally expected, especially as both Exeter and Salisbury are cathedral towns, having considerable open spaces within the city boundaries. But the evidence of overcrowding in these two cities appears much stronger when they are compared with some of the other most populous manufacturing towns: Sheffield, for instance, which is among the densest, has 6263, or little more than half as many on the square mile as Salis-

bury; Bradford, which has 2887, or less than one-fourth; and Blackburn, which has 1333, or only one-eighth. As respects proximity of population, regarding it upon the same hypothesis of equal distribution, we find that the people of England were, in 1801, on an average 153 yards asunder, while in 1851 they were only 108 yards asunder; the mean distance apart of the houses in 1801 being 362 yards, and 252 yards in 1851. Or, as it may be otherwise expressed, on the same area the population has doubled—the proximity has increased—the separation has diminished—in the ratio of 3 to 2. In the London division the mean proximity has increased from 21 yards in 1801 to 14 yards in 1851. The following table shows the density and proximity of population in the eleven divisions of England and Wales in 1851, which are arranged according to the order of density:—

	Yards asunder of People.	To a Square Mile.	
		Persons.	Houses.
I. In London	14	19,375	2,509
VIII. „ North-Western Division (Cheshire and Lancashire)	67	792	139
VI. „ West-Midland Division	100	355	70
IX. „ Yorkshire (nearly the same as all England)	107	313	63
II. „ South-Eastern Division	118	256	47
III. „ South-Midland Division	120	247	49
V. „ South-Western Division	124	231	43
IV. „ Eastern Division	127	222	46
VII. „ North-Midland Division	128	220	45
X. „ Northern Division	142	178	30
XI. „ Welsh Division	157	149	29

“The divisions in which the line of proximity is less than 108 yards have a large proportion of town population; the divisions, of which the line of proximity exceeds 127 yards, contain forests, wastes, fens, or mountains.”

The *Islands of the British Seas* are noticed more fully in this than any previous census. Five hundred islands and rocks have been numbered; but inhabitants were only found on the morning of March 31st, 1851, in 175 islands, or groups of islands. Some of the others are, however, occasionally dwelt on by shepherds during summer. Passing over Ireland, which contained 6,551,970 inhabitants, we find that four of the larger islands have each upwards of 50,000 inhabitants:—Anglesey 57,318, Jersey 57,020, Isle of Man 52,344, Isle of Wight 50,324. Four others have each above 20,000:—Guernsey 29,757, Lewis 22,918, Skye, 21,528, and Shetland 20,936. Two more number upwards of 10,000:—Orkney 16,668, and Islay 12,334. Twenty number between 1000 and 10,000 inhabitants; fifteen between 500 and 1000; thirty-seven between 100 and 500; fifteen between 50 and 100; forty-five between 10 and 50; seven number 10 inhabitants on each; and twenty-five under 10, two of them having only one inhabitant on each, Little Papa, one of the Shetlands, a woman, and Inchcolm, in Fifeshire, a man. Some of the more remote and smaller islands were now numbered for the first time, and much curious information was collected.

The number of *Boroughs* in England and Wales having municipal organisation according to the Municipal Reform Act, was 196, with a population of 4,345,269; of these boroughs, 18 have had charters of incorporation granted since the passing of that Act. There are 89 unreformed boroughs. Of the reformed boroughs it is found that one-half of the population (2,220,542) is contained in 17 boroughs, each of which contains more than 60,000 inhabitants. It appears also that 102 boroughs, or more than half of the total number, contain less than 9,000 inhabitants in each; in the aggregate, 472,551 inhabitants. Eighty-seven boroughs have from 2,000 to 7,000 inhabitants; twenty-seven, from 20,000 to 40,000; eight, from 40,000 to 60,000; seven, from 60,000 to 80,000; two, from 80,000 to 100,000; and three have 200,000 and upwards.

The 83 royal and municipal burghs of Scotland contained 752,777 inhabitants; only three burghs contained more than 60,000 inhabitants; one, more than 40,000; three, from 20,000 to 40,000; fifteen, from 7,000 to 20,000; thirty-three, from 2,000 to 7,000; and twenty-eight under 2,000 inhabitants.

Several of the most populous and important places in England and Wales are still without a municipal organisation. Among these are the metropolitan parliamentary boroughs of the Tower Hamlets, population 539,111; Finsbury, 323,772; Marylebone, 370,957; Greenwich, 105,784; Lambeth, 251,345; and Westminster, 241,611; and the towns of Burnley, 20,828; Bury, 31,262; Chatham, 28,424; Cheltenham, 35,051; Dudley, 37,962; Huddersfield, 30,880; Merthyr Tydfil, 63,080; Rochdale, 29,195; Stroud, 36,535; and Stoke-upon-Trent, 84,027. In Scotland there are no towns containing a population of 10,000 which are not municipal burghs.

One of the subjects most carefully considered in taking the Census of 1851, was that of the *Occupations of the People*. In the previous decennial enumerations, an inquiry of a similar kind was instituted, but with less minuteness. In 1851, to use the words of the Registrar-General, “It was considered important to extend the inquiry, so as to show, as nearly as was practicable, the number of men, women, and children in every trade and profession;” and it was further held to be desirable, notwithstanding the great additional labour entailed in ab-

stracting and tabulating the results, “not only to take out the number of persons of each sex in each occupation, but the numbers at each quinquennial period of age; for without this information the relative salubrity of the professions, and a great variety of important questions, cannot be determined.” The results of the inquiries instituted were embodied in a bulky but very able report, published subsequently to the General Report; and in it the subject is examined as a whole, and in detail from various points of view, and numerous elaborate tables present the results as digested after a vast amount of labour and consideration.

In looking at the tables with regard to the more general results, there are many interesting particulars which become developed. Thus: one-half of the total population is 10,479,738. Now this is almost exactly identical with the number (10,418,989) of those set down under some domestic appellation, as wife, widow, daughter, grand-daughter, sister, niece, son, grandson, brother, nephew, child under tuition at home, child under tuition at school; that is, persons to whom no occupation whatever is attributed, but who are regarded as dependent on the head of the family for support. Regarded in this light, therefore, just one-half of the population have nothing, and do nothing to earn a living; they are the home-members of a family; they may assist in domestic labours, but they do not work at money-getting employments. There are then left half the population, who either possess wealth already accumulated, or exercise their hands and heads in the acquisition of wealth; of this half, one moiety can, with a near approach to correctness, be divided into five equal parts, thus:—

About 1,000,000 domestic servants.

„ 1,000,000 employed in preparing the materials for dress.

„ 1,000,000 employed in making dress.

„ 1,000,000 ordinary agricultural labourers (males.)

„ 1,000,000 other persons, male and female, living by farm and field operations.

Most of these numbers are slightly over the million. If we suppose the two millions of farmers, graziers, gardeners, and in-door and outdoor farm-servants of every kind, to be all employed in raising food (and this is not such a wide departure from the truth as to vitiate such general results as we have now in view), it brings us to this conclusion: of the total population, about 21,000,000, there are:—

Of family dependents, having no definite

occupation = about one-half.

Of persons supplying dress, food, or do-

mestic service = about one-quarter.

Of persons employed in all other occu-

pations = about one-quarter.

In preparing their vast tables of the distribution of occupations in the respective divisions, counties, districts, and towns, the commissioners had to determine how many different occupations should be given in each table. In the whole there were 1057 occupations for males returned. These, for the purpose of tabulation, would have been utterly unmanageable; they therefore, after much consideration, reduced them into 17 groups, or classes of persons having definite occupations, and these they again divided into 91 sub-classes. The list of their principal classes will give some notion of their mode of procedure:—1. Persons engaged in the general or local government of the country. 2. Persons engaged in the defence of the country. 3. Persons in the learned professions. 4. Persons engaged in literature, fine arts, and science. 5. Persons returned only as children, or relations and scholars. 6. Persons engaged in entertaining, clothing, and performing personal offices for man. 7. Persons who buy or sell, keep, let, or lend money, houses, or goods of various kinds. 8. Persons engaged in the conveyance of men, animals, goods, and messages. 9. Persons possessing or working the land, and engaged in growing grain, fruits, grasses, animals, and other products. 10. Persons engaged about animals. 11. Persons engaged in art and mechanical productions. 12. Persons working and dealing in animal substances. 13. Persons working and dealing in vegetable substances. 14. Persons working and dealing in minerals. 15. Labourers and others—branch of labour undefined. 16. Persons of rank or property, not returned under an office or occupation. 17. Persons supported by the community, and of no specified occupation.

The classification was, in a measure, arbitrary and unsatisfactory, as yoking together occupations of a very dissimilar kind; but it was convenient, and, with some modifications, will probably be adhered to in future enumerations.

The 91 sub-classes were subdivided into the 1057 occupations or employments for males. A separate classification for females amounts to 746 employments. These are, of course, in some cases identical with those of men; in other cases, nearly alike but differently named; while in others they are wholly distinct and feminine in their character.

Taking the 1057 occupations for males, just as they stand in the classified tables, the highest numbers are the following, comprising those exceeding 40,000 persons in each employment:—

Agricultural labourers	1,006,728
Labourers (undefined)	367,472
Farmers	275,676

Shoemakers	243,052
Farm-servants, indoor	235,943
Cotton-spinners and weavers	222,612
Coal miners	216,366
Carpenters	182,546
Tailors	135,028
Blacksmiths	112,184
Masons	101,391
Porters and messengers	97,642
Merchant seamen	89,206
Woollen spinners and weavers	86,649
Domestic servants	79,615
Gardeners	78,462
Grocers	68,242
Butchers	65,912
Plumbers, painters, and glaziers	62,421
Carmen and drivers	56,252
Bakers	55,663
Worsted spinners and weavers	51,863
Engineers and machinists	48,050
Silk spinners and weavers	45,169
Clerks (commercial)	43,741

Among females of twenty years of age and upwards, the highest numbers placed opposite definite occupations are the following:—

Domestic servants (general)	401,950
Milliners	202,437
Cotton-spinners and weavers	143,212
Washerwomen and manglers	136,532
Farm-servants, in-door	67,538
„ out-door	56,067

These numbers, however, must not be used for any inferential purpose, without taking others belonging to employments collaterally connected with them. Thus, the 401,950 *general* servants do not include about 200,000 others who enter themselves under the more specific designations of housekeeper, housemaid, cook, nurse, and inn servant; the 202,437 milliners are irrespective of 140,000 seamstresses and needlewomen of other kinds; and so in other cases. It must also be borne in mind, in respect both of the male and the female lists, that the highest numbers are attached to designations which are rather degrees of relationship than occupations. For instance, we find—

Wives (not otherwise specified)	2,631,380
Children and relations at home, ditto	4,745,217
Children who attend school, ditto	2,752,737

Here we have at once more than a third of the entire population entered under three headings, excluding everything like a business designation.

As a summary of results relating to occupations generally, without regard to age, sex, or topographical distribution, it may be profitable to give the annexed table, containing the commissioners' own enumeration of the number of persons employed in 108 avocations in Great Britain, comprising all those for or in respect of which the numbers exceed 10,000. Mere domestic relationship, such as "wife," "widow," &c., is not here taken into account; all are "occupations," in the usual meaning of that word—male or female, adult or juvenile.

OCCUPATIONS IN GREAT BRITAIN, AND NUMBER OF PERSONS ENGAGED IN THEM (ARRANGED IN THE ORDER OF THE NUMBERS), IN 1851:—

Occupations.	Persons.	Occupations.	Persons.
Agricultural labourer, farm		Linen, flax manufacture	98,860
servant, shepherd	1,460,896	Seaman (merchant service)	
Domestic servant	1,038,791	on shore or in British	
Cotton, calico, manufacture,		ports	89,206
printing and dyeing	501,465	Grocer	85,913
Labourer (branch undefined)	376,551	Gardener	80,946
Farmer, grazier	306,767	Iron manufacture, moulder,	
Boot and shoe maker	274,451	founder	80,032
Milliner, dressmaker	267,791	Innkeeper, licensed victual-	
Coal-miner	219,015	ler, beershop-keeper	75,721
Carpenter, joiner	182,696	Seamstress, shirtmaker	73,068
Army and navy	*178,773	Bricklayer	67,989
Tailor	152,672	Butcher, meat-salesman	67,691
Washerwoman, mangler,		Hose (stocking) manufacture	65,499
laundry-keeper	146,091	School-master, mistress	63,376
Woollen cloth manufacture	137,814	Lace manufacture	63,660
Silk manufacture	114,570	Plumber, painter, glazier	62,808
Blacksmith	112,776	Baker	62,472
Worsted manufacture	104,061	Carman, carrier, carter,	
Mason, paviour	101,442	drayman	56,981
Messenger, porter, errand-		Charwoman	55,423
boy	101,425	Draper (linen and woollen)	49,184

* This is the Army and Navy of the United Kingdom, exclusive of the Indian Army and Navy.

Occupations.	Persons.	Occupations.	Persons.
Engine and machine maker	48,082	Warehouse-man, -woman	17,861
Commercial clerk	43,760	Saddler, harness maker	17,583
Cabinet-maker, upholsterer	40,897	Hatter, hat manufacture	16,975
Teacher (various), gover-		Coachman (not domestic ser-	
ness	40,575	vant), guard, postboy	16,836
Fisher-man, -woman	38,294	Law clerk	16,626
Boat, barge, -man, -woman	37,683	Coachmaker	16,590
Miller	37,268	Cow-keeper, milk-seller	16,526
Earthenware manufacture	36,512	Ropemaker	15,966
Sawyer	35,443	Druggist	15,643
Railway labourer	34,306	Surgeon, apothecary	15,163
Straw-plait manufacture	32,062	Tin miner	15,050
Brick maker, dealer	31,168	Paper manufacture	14,501
Government civil service	30,963	Coalheaver, coal labourer	14,426

Police	18,348	Merchant	10,256
Plasterer	17,980	Ribbon manufacturer	10,074

Leaving these general results, which apply for the most part to the whole of Great Britain, and to the whole circle of occupations, we proceed to notice a few of the results having a somewhat more special character. One of these has relation to the employment of the many by the few, and another relates to farms, farmers, and farm-labourers.

One of the valuable results of the Census of 1851, is the determination, to a certain degree of correctness, of the relative positions of employers and employed; a classification of masters and men in each occupation. Many of the schedules sent by the commissioners were imperfectly filled up; but the general result approximates on the whole pretty nearly to accuracy. We may solve many interesting questions by means of the tables thus produced. For instance, let the question be this: How many occupations are there in which some of the masters employ 350 hands or more? They are the following:—shoemakers, glove-makers, stocking-weavers, engine and machine makers, builders, carpenters, manufacturing chemists, tanners, woollen manufacturers, worsted manufacturers, flannel manufacturers, woollen dyers, silk manufacturers, ribbon manufacturers, fancy goods manufacturers, shawl manufacturers, brewers, cotton manufacturers, lace manufacturers, paper-makers, stationers, coal-merchants, coal-miners, contractors, earthenware manufacturers, glass manufacturers, silversmiths, tin-plate workers, white metal workers, button-makers, iron manufacturers. Let the question be,—Which occupations contain the greatest number of firms employing 350 or more persons each? We find, in answer, 113 cotton manufacturers, 21 woollen manufacturers, 13 silk manufacturers, 12 worsted manufacturers, 14 engine and machine makers, 7 earthenware manufacturers, 5 iron manufacturers, 5 builders. Let the question be,—How many masters employ bodies of men not less than 100 in number? The answer, slightly classified, comes out as follows:—

390 masters employ from 100 to 150 men each	
236 „ „ 150 to 200 „	
135 „ „ 200 to 250 „	
88 „ „ 250 to 300 „	
65 „ „ 300 to 350 „	
228 „ „ 350 and upwards „	

1142 masters each employ 100 men or upwards.

These and similar questions are in the report followed out in great detail, and with reference to the great centres of the particular branches of national industry, but our space does not permit us to continue the subject further.

In respect of agricultural pursuits, the commissioners sought to obtain a return of the number of farms, the size of the farms, and the

number of persons engaged in them. The following is a convenient general outline of the result:—

Size of Farms. Acres.	Number of Farms.			
	Great Britain.	England and Wales.	Scotland.	Islands in British Seas.
Total . .	283,378	223,271	56,150	3,957
Under 100	190,573	142,358	44,469	3,746
100	52,912	45,752	7,009	151
200	20,603	18,401	2,166	36
300	9,031	8,061	961	9
400	4,063	3,585	471	7
500	2,248	1,971	272	5
600	2,816	2,372	442	2
1000	1,132	771	360	1
and upwards.				

Besides the above, there were 2558 farms of which the sizes were not stated in the returns, making 285,936 farms or farm-holdings altogether. It is found that large farms prevail most in the north, and in Norfolk and Suffolk. The average size of all the farms is 102 acres; and, taken in the aggregate, they occupy just about one-half of the territory of Great Britain. Two-thirds of the farms are less than 100 acres each in extent. About 9000 small farmers seem to have no labourers except the members of their own families; about 170 farmers employ more than 60 labourers each; while all the rest have in their service a number varying from 1 to 60.

Professional avocations, as distinguished from trading and manufacturing, may be brought together in the following form:—

Persons engaged in the general or local government of the country:—	Males.	Females.
Civil Service	38,849	1,487
Local service	29,851	1,113
East India (in England)	3,774	—
Persons engaged in the defence of the country:—		
*Army, with pensioners, &c., at home.	70,718	—
Navy	25,796	—
Persons engaged in religious duties:—		
Clergymen of national churches	18,587	—
Other ministers (and not returned under any secular calling)	9,614	—
Subordinate officers	6,371	879
Persons engaged in law and justice:—		
Judges	85	—
Barristers, advocates, &c.	3,111	—
Solicitors, attorneys, &c.	13,582	—
Law students	1,659	—
Law clerks, &c.	19,149	—
Persons engaged in the medical profession:—		
Physicians	2,328	—
Surgeons and apothecaries	15,163	—
Chemists and druggists	15,333	—
Students and assistants	3,655	—
Miscellaneous	2,012	751
Persons engaged in literature, the fine arts, and sciences:—		
Authors, editors, &c.	2,949	118
Artists, architects, &c.	8,609	536
Scientific persons	496	22
Professors and teachers	34,150	71,957
Actors and actresses, theatre servants	1,485	785
Musicians and vocalists	6,081	798
Engravers	5,507	77
Carvers and modellers	2,293	75
Pattern designers	2,161	43
Draughtsmen	597	—
Medallists and die-sinkers	489	14

Supposing that the above may be fairly reckoned as professional employments, it appears that, on Census-day in 1851, there were 344,464 males and 78,467 females thus occupied. These comprise 1 in 30 of all the males, 1 in 140 of all the females, and 1 in 50 of the whole population. If we omit the sailors and soldiers from the list of professional men, the ratio will become about 1 in 60.

Some of the most curious, probably some of the most valuable, tables in the Census Reports are those which establish a comparison between different parts of the country. Large generalisations may be made from the tables which relate to the whole of Great Britain; but for comparison and analogy, the sectional tables have a peculiar value of their own. In reference to a particular department of occupation, or a particular social relation, we may wish to know how far Wales differs from England, and Scotland from both; how far the 10 divisions into which England is separated differ one from another in characteristics;

* But the total of the Queen's forces, at home and abroad, naval and military, effectives and non-effectives, was 262,570.

in what way the 40 English counties, 12 Welsh counties, and 32 Scotch counties exhibit peculiar characteristics; by what peculiarities the 623 registration districts or poor-law unions of England and Wales are distinguished; and so forth. The voluminous census tables afford a store of information on all these local details.

Of course, when different districts or portions of the kingdom are treated separately, the metropolis comes in for the first notice; the following, then, is a rough outline of employments generally in the metropolis. Confining our attention, at present, to males, and to males only of 20 years and upwards, we find the following facts: That out of the 5,458,815 males of 20 years and upwards in Great Britain, 632,545 live in the metropolis; that the London shoemakers number 26,639, and the London tailors 20,257; that there are no fewer than 25,708 domestic and inn servants; that the commercial establishments are so numerous and extensive as to employ 15,135 clerks and travellers; that the coachmen, drivers, carriers, waggoners, draymen, and others who drive vehicles through the London streets, number more than 17,000, besides 14,000 messengers and porters, in addition to railway, canal, and river servants; that there are, for house-work, 21,174 carpenters, 13,817 painters and glaziers, and 16,038 bricklayers and plasterers; that among those who supply us with food and drink, are 9841 bakers, 7428 butchers, 6843 publicans, 6475 grocers, 3372 milk-sellers, 3325 greengrocers, 2238 fishmongers, and 2156 cheesemongers; that the leather trades, chiefly in Bermondsey, employ 5391; that there are 13,206 persons employed in printing, binding, and selling books; that the wood-furniture makers and sellers number 13,574; and that there are more than 40,000 labourers whose branch of labour is undefined, but who must be distinguished from skilled artisans.

Let us next—still confining our attention to the metropolis—glance at the female occupations in a similar way. Among the 5,998,384 females, aged 20 years and upwards, living in Great Britain, 762,418 are in London. Of this number, 316,517 designate themselves simply as wives, and 26,627 simply as widows, and about 40,000 as daughters, without any other alleged employment. But of those who appear to earn their living by the labour of their own hands or brains, there are no fewer than 118,855 domestic servants of various kinds, 73,620 needlewomen of various kinds, and 45,754 charwomen, washerwomen, and manglers. These, with 25,652 annuitants, and gentlewomen of independent means, comprise all the large items among the female adult population of the metropolis; all the other items are, individually, very small. These facts are not without their instruction; for they show how limited is the range of female employments in London. They show too, that, after deducting those who are dependent on relations for support, and those of independent means, there were 330,000 adult females in London in 1851 dependent on their own exertions for their daily bread; and they show also how large must be the number of families in comfortable circumstances in London, to give employment to nearly 120,000 female servants and 45,000 laundry- and charwomen.

But now let us compare one of the manufacturing counties of the North with London, to ascertain how far a different principle seems to determine the distribution of occupations. We take the cotton-spinning county of Lancashire. Here we have 539,075 males of 20 years of age or upwards, against 632,545 in the metropolis; that is, in the ratio of about 85 to 100. Different indeed, however, is the ratio in regard to employments. We have seen that the metropolis contains about 26,000 male adult servants, 31,000 drivers and porters, 27,000 shoemakers, 21,000 carpenters, 20,000 tailors, 16,000 bricklayers, 15,000 clerks, 14,000 painters; whereas, in Lancashire, these eight occupations exhibit the numbers 4708, 9127, 15,443, 12,146, 11,346, 7658, 7643, 6336—all far below the ratio in respect to total inhabitants. In London there are 35,000 persons in the public service, receiving emoluments from the community at large; whereas in Lancashire there are only 11,000. In London there are 34,000 professional men, engaged in divinity, law, physic, science, and fine arts; in Lancashire the number is 11,000. In London there are 14,000 persons employed in writing, printing, binding, and selling books and periodicals; in Lancashire there are 2000. All these numbers, it is evident at a glance, differ widely; London having far more than its ratio of 100 to 85 in each of these employments. But let us turn the tables, and see what are the employments wherein Lancashire takes precedence of the metropolis. Of course, in a county, farmers, graziers, shepherds, gardeners, agricultural labourers, and so forth, must be relatively more numerous than in a city; and thus we need not be surprised to find 56,000 of these in Lancashire, against 14,000 in the metropolis. And, considering the wonderful shipping activity of Liverpool, and the numerous canals which traverse Lancashire in every direction, we may be prepared to expect that this county and the metropolis are not far from equal in the numbers of persons connected with ships, boats, and barges in various capacities; in the metropolis this number is about 21,000, in Lancashire 18,000—very nearly, indeed, in the ratio of 100 to 85. But it is in textile manufactures, and in minerals, that Lancashire most decidedly takes the lead before London. In Lancashire there are 104,000 persons (out of about 540,000) engaged in various departments of the cotton manufacture, against a few hundreds in London; 7000 in woollen manufactures, against a few hundreds; 21,000 coal miners and labourers, against 5000; 3000 quarrymen, against 500.

Here it must be borne in mind, that the numbers in the preceding

paragraph are of males only, and males too who have reached their 20th year or upwards. A few parallel entries will suffice, relating to certain occupations for adult females: of domestic servants and nurses there are 125,000 in London, and 55,000 in Lancashire; of silk-workers, 8000 in London, and 12,000 in Lancashire; of cotton-workers, 1000 in London, and 90,000 in Lancashire. Here we find that one-sixth of all the adult females in London are domestic servants or nurses, and that one-sixth of all the adult females in Lancashire are engaged in the cotton manufacture.

There are also striking differences in respect to juvenile labour:—The metropolis contains 474,013 males, and 493,260 females, under 20 years of age; the numbers in Lancashire are 469,749 and 474,735 respectively. Now in the metropolis, after deducting 770,000 young persons who are entered only in their domestic or family relations, without connection with any particular employments, there remain about 200,000 who are considered to have some occupation or other; whereas in Lancashire there are 270,000 having employment; and out of this number about 120,000 are employed in the cotton manufacture alone—that is, 120,000 young persons. In the metropolis, on the other hand, young seamstresses and young domestic servants chiefly fill the list.

We turn now to other phases of metropolitan employment. Of the whole 2,362,236 inhabitants, there are, in round numbers, 630,000 men, 760,000 women, and 970,000 persons of both sexes under 20 years of age. Of this latter number, nearly 300,000 are under five years of age, and therefore almost equally removed from schooling and occupation. In order to show, then, how far male employments are to be met with in London for young persons, we give the following table in relation to a few occupations:—

	Under 20.	20 and upwards.
Law clerks	1,530	5,401
Teachers	457	4,285
Messengers and porters	19,743	13,471
Printers, &c.	3,213	13,206
Silk manufacturers	1,435	8,388
Cabinet-makers	2,361	13,963
Gold and silver work	1,145	6,419
Brass work	1,066	5,358
Iron work	2,170	13,604
Building trades	6,981	59,451

It is probable that the greater part of the above young persons are apprentices, although the returns do not specify this fact in words. The 19,743 young messengers and porters are evidently the "errand boys," rather a formidable body in London. Taking female occupations instead of male, and noticing the difference of age in a similar manner, we find the following:—

	Under 20.	20 and upwards.
Teachers	1,314	11,185
Servants	46,524	138,262
Needlewomen	20,288	124,165
Silk-workers	2,373	8,847
Paper-workers	625	1,132

If we were to name the three most characteristic kinds of occupations in London for males under 20 years of age, therefore, they would be apprentices to mechanical trades, errand boys, and junior clerks; and for females under 20 years of age, they would be servants, needlewomen, and teachers.

The Report enables us to follow the subject of the industrial occupations of the metropolis in very minute detail, the distributions of trades in particular localities, &c., but it will be more satisfactory perhaps to occupy our remaining space with a rapid comparison of the occupations of some of the more remarkable districts of the country, or such as illustrate broad general principles of industrial distribution. Take a few of the principal manufacturing towns in succession.

Birmingham.—Here the males under 20 years of age (or, as we shall for brevity call them, boys) are 52,640, and above 20 years (men) 61,276; the females under 20 (girls) are 53,380, and above that age (women) 65,545. The leading trades are connected with working in metal. In round numbers 2000 men are employed in making guns, 1800 making machines and tools, 2400 working in gold and silver, 3000 are brass founders, 1400 button makers, 1200 white and black smiths, 1400 iron manufacturers, 400 nail makers. Of the males under 20, no less than 7000 are employed in the few metal trades above enumerated. In Birmingham, 1300 young females and 1600 adult females are employed in making buttons, 700 and 1100 in miscellaneous works in mixed metal, 800 and 1200 in miscellaneous iron and steel works.

Manchester and Salford.—In these cotton towns are—

Males.	Females.	Total.
86,551 +	89,043 =	175,594 under 20 years.
104,906 +	120,821 =	225,727 20 and upwards.
191,457 +	209,864 =	401,321 total population.

Here one single entry, cotton manufacture, comprises enormous numbers—13,257 men, 5692 boys, 14,503 women, 9051 girls, making a total of 42,503, in which the females exceed the males by 23,554

against 18,949. Putting the whole of the textile manufactures together—relating to cotton, flax, silk, and wool, they appear to employ about 25,000 men, 8000 boys, 20,000 women, and 12,000 girls, exhibiting the remarkably near equality of 33,000 males to 32,000 females—more than 1 in 7 of the entire population of Manchester and Salford employed in making the textile materials for dress, besides 12,000 tailors and seamstresses employed in making up textile materials into dress.

Nottingham.—Here we enter a bobbin-net and cotton stocking town:—

Males.	Females.	Total.
11,782 +	12,746 =	24,528 under 20 years.
14,805 +	18,074 =	32,879 20 and upwards.
26,587 +	30,820 =	57,407 total population.

Of these we find—stocking-makers, 2469 men, 412 boys, 1588 women, 474 girls, making nearly 5000 persons, or more than one-twelfth of the whole of the inhabitants, employed in this one branch alone. The bobbin-net manufacture employs 1376 men, 517 boys, 3277 women, 1902 girls, exhibiting a still more striking total of more than 7000 persons. Of the aggregate 12,000, more than 7000 are females. It is worthy of notice that the hose and lace-workers bear a larger ratio to the population of Nottingham, than the whole of the textile workers bear to the population of Manchester.

Merthyr Tydvil.—We quit hosiery and lace, to turn to iron and coal:—

Males.	Females.	Total.
14,357 +	13,628 =	27,985 under 20 years.
19,650 +	15,443 =	35,093 20 and upwards.
34,007 +	29,071 =	63,078 total population.

Under the heading "coal miners," are 1671 boys and 4302 men; and among iron workers 2038 boys and 6915 men; making a total of about 15,000 workers in these two minerals alone; these, with 700 or 800 females similarly employed, comprise a quarter of the entire population. Considerably more than half the adult male population of Merthyr Tydvil are workers in iron and coal, employed chiefly in the four great establishments of Dowlais, Cyfarthfa, Pen-y-darren, and Plymouth works.

Bradford.—This busy Yorkshire town introduces us to a wholly different class of manufactures. The parliamentary borough is somewhat extensive, and includes some of the neighbouring villages, comprising a population of—

Males.	Females.	Total.
22,934 +	24,399 =	47,333 under 20 years.
27,032 +	29,413 =	56,445 20 and upwards.
49,966 +	53,812 =	103,778 total population.

Of these are entered, under worsted and stuff manufacture, 5381 boys, 10,759 men, 7936 girls, and 8780 women—a powerful body of about 33,000 persons (nearly a third of the whole population) employed in worsted and stuff manufactures alone. The woollen cloth, the silk, and the cotton manufactures, occupy perhaps 1000 altogether, showing how insignificant they are at Bradford.

Leeds.—The borough contains—

Males.	Females.	Total.
38,468 +	38,987 =	77,455 under 20 years.
45,246 +	49,569 =	94,815 20 and upwards.
83,714 +	88,556 =	172,270 total population.

We devote a short paragraph to Leeds, for the purpose of showing how remarkable a contrast may be presented in the industry of two towns situated only about ten miles apart. Bradford and Leeds both work up wool largely; but Bradford prepares it for stuff or worsted fabrics, while Leeds prepares it for woollen cloth. Leeds has 2920 boys, 7640 men, 1710 girls, and 2624 women employed in making woollen cloth: while the stuff and worsted manufactures barely employ 1000. Leeds, however, is a large manufacturing town in other respects; for it employs about 9000 persons in the flax manufacture, and 3000 in making engines and machines. Relatively to the population, Huddersfield is perhaps more peculiarly associated than Leeds with the woollen cloth manufacture.

Macclesfield.—This borough, the centre of the silk trade, contains—

Males.	Females.	Total.
8,299 +	8,735 =	17,034 under 20 years.
10,242 +	11,772 =	22,014 20 and upwards.
18,541 +	20,507 =	39,048 total population.

Of these, 2462 boys, 4772 men, 2979 girls, and 4339 women are employed in the silk manufacture; making an aggregate of about 14,500 persons, considerably more than one-third of the entire population. The males and females are employed in almost exactly equal numbers, 7234 to 7318.

Sheffield.—In this cutlery borough there are :—

Males.	Females.	Total.
31,108	+ 31,112	= 62,220 under 20 years.
36,392	+ 36,698	= 73,090 20 and upwards.

$$67,500 + 67,810 = 135,310 \text{ total population.}$$

The works in gold, silver, steel, iron, and mixed metals employ about 20,000 men and boys at Sheffield. Females are very little employed in the metal trades, thereby presenting a striking contrast to the arrangements at Birmingham. No fewer than 2461 boys and 7044 men are employed in making and grinding cutlery and files alone.

Glasgow.—There are two or three Scotch towns which present remarkable characteristics. Glasgow has—

Males.	Females.	Total.
71,474	+ 73,593	= 145,067 under 20 years.
83,455	+ 100,574	= 184,029 20 and upwards.

$$154,929 + 174,167 = 329,096 \text{ total population.}$$

This busy city is worthy of note for the degree in which it combines cotton working and iron working, two departments of industry which certainly do not seem to have any very necessary bond of connexion. There are 3449 boys, 11,371 men, 9692 girls, and 16,442 women—about 15,000 males and 26,000 females—employed in various branches of the cotton manufacture. Of all the females in Glasgow, in every age and condition, one in seven is employed in this manufacture. In the metal trades, there are 2600 machine and tool makers, 4800 miners and manufacturers, and 5400 other workers in metal—almost wholly males.

Dundee.—This is the great centre of the flax and linen manufacture of Scotland. Dundee contains—

Males.	Females.	Total.
17,444	+ 17,999	= 35,443 under 20 years.
18,420	+ 25,068	= 43,488 20 and upwards.

$$35,864 + 43,067 = 78,931 \text{ total population.}$$

Of these numbers there are 2713 boys, 6161 men, 4300 girls, and 6568 women, employed in flax and linen manufactures, being almost exactly one-fourth of the whole population—a ratio which certainly appears surprisingly large. Aberdeen is also engaged in these trades, but in a very much smaller ratio than Dundee.

These few examples would perhaps suffice to illustrate the distribution of particular branches of manufacture in the principal towns; but, adopting a still more compressed form we will give a few additional instances in the following way :—

At *Portsmouth*, out of about 35,000 men and boys in the borough, about 9000 are in the public service, and receive pay from the community; while there are about 2000 privately employed as seamen or as shipwrights. At *Leicester*, out of 60,000 persons, nearly 9000 are employed in making worsted stockings and similar articles. At *Northampton*, out of 13,000 men and boys, more than 4000 are employed in making boots and shoes, the staple industry of the place; and at *Stafford* the men and boys similarly employed are in the ratio of one to four of the whole male population. At *Worcester*, out of 15,080 women and girls, 2133 are employed in making gloves. Of the 25,705 men and boys in *Wolverhampton*, about 7500 are employed upon metals or upon coal; no less than 1400 make locks alone. In *Dudley* the ratio is about as high, about 6000 out of 19,093. *Coventry* is remarkable for two trades, about as diverse as any two can be, ribbon-making and watch-making: out of a population of 36,612, nearly 10,000 persons (of whom 6500 persons are females) are employed upon silks and ribbons; while 1700 men and boys are making watches. At *Stockport*, 17,000 persons are employed in cotton manufactures, out of a total population of 53,835—nearly one in three; at *Blackburn*, 16,000 out of 46,536—more than one in three; at *Bolton*, 14,500 out of 61,171; *Oldham*, 20,000 out of 72,357; at *Preston*, 18,000 out of 69,542. Thus, in these five cotton spinning and weaving towns, containing an aggregate of about 300,000 inhabitants, about 34,000 males and 42,000 females—considerably more than one-fourth of all the inhabitants—are engaged in this manufacture. Looking at the distribution of workers in reference to age, we find that there are about 33,000 children and young persons under 20, and 43,000 adults of 20 and upwards. In *Paisley*, out of about 31,000 inhabitants, nearly 9000 are employed in various kinds of textile manufacture, of which the principal is shawls.

Hitherto, in the above paragraphs, we have spoken of distinct towns, each with defined limits and defined number of inhabitants. But a few remarkable manufactures are centred rather in districts than in large towns.

In *Staffordshire*, the registration county contains 320,903 males and 309,641 females. Now, it is plain, on a little examination, that the main departments of industry whereby these are supported have relation to mineral manufactures; and it is further observable, on comparing the several districts, that while the southern exhibit the metallic and colliery operations, the northern are associated with earthenware manufactures. In short, we have the *Wolverhampton* region of the south, and the pottery region of the north. There are 27,000 males and 1000 females engaged in various departments of the

coal trade; 45,000 males and 7000 females in metallic manufactures; 16,000 males and 9000 females in pottery and earthenware manufactures. It is worthy of note, that in the two districts of *Stoke-upon-Trent* and *Wolstanton*, containing the pottery towns of *Stoke*, *Hanley*, *Lane End*, *Delph*, *Etruria*, *Shelton*, *Burslem*, &c., out of a population of 51,000 adult males and females, more than 13,000 are engaged in the earthenware manufacture. It would perhaps scarcely be expected that, in *South Staffordshire*, 5000 women are engaged in nail-making.

Bedfordshire, containing 62,539 males and 67,266 females, is not a county likely to contain large manufacturing establishments of any kind; but there are, nevertheless, two or three entries in the tables which deserve attention. There are, we find, 2300 males and more than 10,000 females engaged in the straw-plait manufacture; together with nearly 6000 females occupied in hand-lace making. One-fourth of all the females in the county, of all ages and conditions, are employed in one or other of these two occupations. In *Buckinghamshire*, containing 70,928 males and 72,727 females, the straw-plait trade is smaller, employing only about 3000 females; but the lace-trade is about as extensive as in *Bedfordshire*, employing nearly 11,000 females. In *Hertfordshire* we almost entirely lose the lace-trade; but the straw-plait employs about 9000 females out of 87,497. In *Cambridgeshire* there is a little done in these two trades, but only a little; and in *Huntingdonshire* there are about 1000 females out of 30,295 engaged in the lace-trade. In these two departments of cottage industry, the females employed are of all ages from 5 to 90, chiefly between 10 and 20.

Worcestershire, for some reason which it is difficult to explain, is the centre of the needle manufacture. At *Redditch*, in this county, nearly all the inhabitants are supported, directly or indirectly, by this manufacture; although the steel for making the needles, and all the coal for heating the steam-engines, must be brought from other quarters.

Cornwall is rich in metals, but has no coals. It has 172,193 males in the (registration) county. Among these are 3000 seamen and 2600 fishermen; but under mineral working, we find about 16,000 copper-miners, more than 10,000 tin-miners, 2500 lead-miners, and about 6000 employed in other ways on metals and minerals; none, however, in coals. There are also above 6000 females engaged at the "above-ground" works of the copper- and tin-mines.

Let us contrast this with a county containing much coal, but little metal. *Durham* (registration) county contains 207,088 males and 204,591 females,—a departure from the general rule, for here we find more males than females. Now, here are 10,000 men and boys engaged in sea and river navigation; a very large number out of such a population, and evidently due principally to the navigation of colliery vessels. The number of 4500 ship and boat builders is also large, and points to the busy trade of *Sunderland*. But a much larger item is that of 29,000 men and boys employed in coal-mining and working, about one-seventh of the male population. In *Northumberland*, as might be expected, a somewhat parallel state of things presents itself. There are here 149,515 males; and of these, about 6000 are engaged in navigating ships and boats, 1400 in building ships and boats, and 11,000 coal-miners; the parallelism, it will be observed, is in the nature of the prevalent occupation, and not in their extent, for *Durham* greatly takes the lead in this respect.

There are two counties in the western part of the kingdom which we may similarly notice, in respect partly to the iron manufacture, but still more decidedly to coal-mining. These are *Monmouthshire* and *Glamorganshire*. *Monmouthshire* contains 92,301 males and 82,849 females—another example, in a mining county, of the males outnumbering the females. The iron trades occupy 12,000 males, and the coal trade also 12,000—in round numbers: together more than one-fourth of the entire male population. Females are not much employed in these trades in this county. *Glamorganshire*, containing the remarkable towns of *Merthyr* and *Aberdare* and their vicinity, has a population of 125,087 males and 115,000 females. Of these males, no less a number than 15,500 are engaged in the coal trade, and 14,000 in the iron trades. In another Welsh county, *Caermarthen*, copper manufactures are, in respect to the population, if not as remarkable as iron manufactures in *Glamorganshire*, at least worthy of note as the staple industry of portions of the country. The explanation of this is, that nearly all the copper ores of *Cornwall* and *Devon* are sold on the spot to copper-smelters, who have their works at *Swansea* or *Neath*, or some other town in *Caermarthen*. But besides the copper workers there are, among the 125,087 males in this county, 14,000 workers in iron, and 15,000 coal-miners.

Such are a few of the striking results obtained by the Census of 1851, relating to the occupations of the people. The entire Report is, however, worthy of the careful study of every person who desires to know something more of the condition of the people, in this hard-working country, than can be derived from vague generalisations and partial inquiries.

Another subject on which it was sought to arrive at some definite results, and on which a separate Report was published, was that of *Religious Worship*. In the Census of 1851, for the first time, the attempt was made to obtain a return of the number of members in the various religious bodies in England and Scotland; but as, for reasons already mentioned, the answers to the questions proposed were not compulsory, but depended on the willingness of the respondent, the

returns are necessarily imperfect. However, in England, returns were sent from 14,077 churches belonging to the Church of England, and from 20,390 places of worship belonging to other religious bodies. The forms issued required information as to the religious denomination of the body; as to the number of places of worship, the number of sittings contained in them; the number of attendants at the morning, afternoon, and evening services on March 30, 1851; with the number of places of worship actually open on that day, and the number of available sittings. The result gave the following thirty-six denominations:—

- | | |
|---|---------------------------|
| 1. Church of England and Ireland. | |
| 2. Church of Scotland, | |
| 3. United Presbyterian Synod, | } Scottish Presbyterians. |
| 4. Presbyterian Church in England | |
| 5. Independents, or Congregationalists. | |
| 6. General | } Baptists. |
| 7. Particular | |
| 8. Seventh Day | |
| 9. Scotch | |
| 10. New Connexion General | |
| 11. Society of Friends. | |
| 12. Unitarians. | |
| 13. Moravians, or United Brethren. | |
| 14. Original Connexion | } Wesleyan Methodists. |
| 15. New Connexion | |
| 16. Primitive Methodists | |
| 17. Bible Christians | |
| 18. Wesleyan Association | } Calvinistic Methodists. |
| 19. Independent Methodists | |
| 20. Wesleyan Reformers | |
| 21. Welsh Calvinistic Methodists | |
| 22. Countess of Huntingdon's Connexion | |
| 23. Sandemanians, or Glassites. | |
| 24. New Church. | |
| 25. Brethren. | |
| 26. Lutherans. | |
| 27. German Protestant Reformers. | |
| 28. Reformed Church of the Netherlands. | |
| 29. French Protestants. | |
| 30. Roman Catholics. | |
| 31. Greek Church. | |
| 32. German Catholics. | |
| 33. Italian Reformers. | |
| 34. Catholic and Apostolic Church. | |
| 35. Latter-day Saints, or Mormons. | |
| 36. Jews. | |

Of the total 34,467 places in England making any return, there were 1394 in which the returns were in some respects incomplete. Perfecting these by estimate, it would appear that there were on the whole 4,647,482 morning attendances, 3,184,135 attendances in the afternoon, and 3,064,449 in the evening. The number of sittings available in the morning was 8,498,520, which may be taken as the total provision for the accommodation of worshippers; the smaller number of sittings returned for afternoon and evening arising, no doubt, from service not being performed three times a day in very many cases. Of the gross number of attendances, which amounted to 10,896,066, there were 5,292,551 to the Church of England; 80,510 to the various Presbyterian places of worship; 1,214,059 to those of Independents; 930,190 to Baptist; 22,478 to Quaker; 50,061 to Unitarian; 10,874 to Moravian; 2,417,353 to the various branches of Wesleyanism; 308,754 to the Calvinistic; 756, Sandemanian; 10,352, New Church; 17,592 Brethren; and 104,675, of isolated congregations. Of the Lutherans, French and German Protestants, there were 2073 attendances; of Roman Catholics, 383,630; of German Catholics, Italian Reformers, and the Apostolic Church, 8262; of Mormons, 35,626; and of Jews, 6030.

In Scotland, on the same day, including an estimate for defective returns, the places of worship were 3395; the number of sittings available, 1,834,805; and the total number of attendants in the morning was 943,951; in the afternoon, 619,863; and in the evening, 188,874. The number of denominations were more numerous than in England, amounting to 40; but the number of the members was very small. The various branches of the Presbyterian church furnished 718,374 of the morning attendants, 542,620 in the afternoon, and

130,468 in the evening. Of the remainder, the Episcopal Church furnished 43,904 total attendants; the Independents, 70,531; the Baptists, 20,958; the Wesleyans, 21,676; the Roman Catholics, 79,823; while the remainder only number from a few hundred each, down to the Jews, who amount to seven.

The above returns, though interesting, it must be distinctly understood, fail to present an accurate view of the state of religious parties in Great Britain. In the first place, there are many minor distinctions of sects which have not been attended to; the estimates for imperfect returns are made on the same principle for all the sects, no allowance is made for variance of manners and customs; for instance, with Presbyterians, most attend the morning and afternoon services, but the evening service is, in many cases, only attended by those who are unable to attend earlier; in the Church of England, the majority of those who attend morning service do not attend again, or if they do, it is in the evening, and in very many country parishes there is only one service a day. Still, though inaccurate in details, the returns cannot fail to show the great features of the chief religious bodies existing among us.

The Census of 1851 also collected some information respecting the state of education; but as there are a variety of other returns on the same subject, the whole will be better treated of under the head of SCHOOLS; the results connected with the inquiries as to the number of the blind, are given under BLIND, CENSUS OF; and dumb persons, their ages, distribution, &c., will be better spoken of in the article DEAF AND DUMB.

With respect to *Ireland*, the circumstance brought out with most startling prominence was the remarkable decrease in the population since the previous Census. Up to that of 1841 each decennial Census of the half-century had shown a steady if not rapid increase of the population. That of 1851 showed that during the past ten years the gain of the previous 20 had been more than undone. In 1821 the total population of Ireland was 6,801,827; in 1851 it was only 6,551,970. And the returns further showed that this decrease was general as compared with 1841; and even as compared with 1821, the only exceptions were some two or three places in Ulster, in each of which, from causes easily understood, there had been a continuous increase of inhabitants during the half century. The large falling off of the population between 1841 and 1851 was mainly owing to the disastrous famine which afflicted Ireland in 1845—47, in consequence of the failure of the potato crop; partly, however, it was due to emigration, which, in its turn, had been greatly stimulated by the failure of the potato, and the consequent agricultural distress. The total emigration from Ireland during the ten years between 1841 and 1851 is estimated to have amounted to 1,289,133, "varying with considerable regularity according to the variations in the state of the labouring classes." For the sake of presenting in one view the increase and decrease of the population of Ireland, we append a table of the number of inhabitants in the four provinces at each decennial Census from 1821 to 1851.

POPULATION.

Provinces.	Area in Acres.	1821	1831	1841	1851
Leinster . . .	4,876,211	1,757,492	1,909,713	1,973,731	1,672,591
Munster . . .	6,064,579	1,935,612	2,227,152	2,396,161	1,857,412
Ulster . . .	5,475,438	1,998,494	2,286,622	2,386,373	2,011,756
Connaught . . .	4,392,043	1,110,229	1,343,914	1,418,859	1,010,211
Total of Ireland	20,808,271	6,801,827	7,767,401	8,175,124	6,551,970

The decrease of population was, as might be expected, most marked in the rural districts. In several of the large towns the census of 1851 showed an actual increase of population, while scarce any showed a falling off, a circumstance arising no doubt from the famishing poor having crowded into them in the hope of obtaining employment or of finding relief. Dublin city, which in 1821 contained 185,881 inhabitants, had 232,726 in 1841, and 258,361 in 1851. Cork, though it showed a decline of nearly 15,000 between 1821 and 1851, showed an increase of above 1000 from 1841. Belfast had more than doubled in population between 1821 and 1851, and between 1841 and 1851 had increased from 75,308 to 100,300. Galway town, which between 1831 and 1841 had fallen in population from 33,120 to 17,275 had increased in 1851 to 23,695.

AREA, HOUSES, AND POPULATION, ON MARCH 31ST, 1851.

	Area in Acres.	HOUSES.			POPULATION.		
		Inhabited.	Uninhabited.	Building.	Persons.	Males.	Females.

Great Britain and Islands in British Seas }	87	815	10,556,288	10,403,189	2,024,648	55,599,729

The two preceding tables will show in the readiest manner the general results of the enumeration of 1851.

We add tables of the population of the counties of Great Britain and Ireland, and the areas in acres, according to the Census of 1851; with the addition, for the sake of comparison, of the enumeration at the first census of Great Britain in 1801, of Ireland in 1821.

CENTAUR, in mythology, a compound of horse and man, supposed to have sprung from the amour between Ixion and the Cloud, which he mistook for Juno: their name has been thought to point to their origin (*κεντ-ειν, αρ-αν*); but this explanation can hardly be admitted. It is not improbable that their existence may have been imagined from the first sight of a man on horseback, and as their history makes them neighbours of the Lapithæ, it is probable that they were merely one of

those Thessalian tribes among whom the far-famed cavalry of that nation took its rise. They are also called Hippocentaurs. Palaephatus's account of the origin of their name (*ἀπὸ τοῦ κεντεῖν τοὺς ταύρους*) is a mere invention, and, in point of etymology, quite inadmissible.

The story of the battle of the Centaurs and the Lapithæ, which formed so favourite a subject with Greek artists, is to the effect that Eurytion, a Centaur, having at the nuptial feast of Pirithous king of the Lapithæ, offered violence to the bride Hippodamia, was instantly slain by Theseus the friend of Perithous. The other Centaurs present sought to avenge the death of Eurytion, and to carry off the female guests. A general fight ensued: and war continued for some time with varying success between the combatants, but eventually the Centaurs were vanquished, and driven out of Thessaly. They found a refuge on Mount Pindus; but here they provoked the anger of Hercules, who destroyed the whole of the race.

The battle of the Centaurs and the Lapithæ forms the subject of the metopes of the Parthenon, part of which are now in the British Museum; and also one of the two subjects represented on the Phigalean frieze, which is also in the British Museum. We give an example from each.

[From the Metopes of the Parthenon, now in the British Museum.]

[From the frieze of the temple at Phigalia, now in the British Museum.]

CENTAURUS, the Centaur, a southern constellation, a very small part of which rises in our latitude. It is situated under Virgo and Libra, and is evidently connected with LUPUS and ARA. From Ptolemy's catalogue, it is evident that he considered the Centaur as holding the wolf (or wild beast, as it is called) in one hand, and a thyrsus in the other; and from the proximity of the altar, it is plain that a sacrifice is alluded to. According to Grotius (notes on Aratus), the thyrsus anciently had a hare hanging from it. In some older figures, the Centaur holds a spear in both hands, which sustains the wolf, passing through its head. Hyginus makes only one constellation of Centaurus and Lupus.

The following are the principal stars in this constellation:—

CENTERING. A centering, in building operations, is understood to mean a wooden, or other temporary, support, upon which the materials of an arch, whether of stone, brick, iron, or other substance, are supported during the execution of the work. Under these circumstances, the essential properties of a centre are that—1, it should be able to support the load to be placed upon it without sensible deflection; 2, that it should be easily and economically fixed; and, 3, that it should be susceptible of being easily and economically removed, without in any way endangering the solidity of the work it had previously supported. Evidently, local considerations must materially affect all these properties; for the width of the opening to be spanned by the centre, and the clear height to be left under the wood framing, must materially influence the modes of construction adopted in it; and thus pre-

cisely in accordance with the importance of the stream to be bridged will be the difficulty of constructing the centres to be used over it. In designing a centre, it must also be borne in mind, that the peculiar construction in question is distinctly a temporary one; and that therefore it should be put together in such wise as to allow the timber which enters into its composition to be reconverted, without material loss to the contractor from the waste of material, or the deep cuttings made into the said timber.

Centres may be described, nearly in the language of Tredgold, as being composed, in ordinary practice, "of several separate vertical frames, or trusses, connected together with horizontal ties, and stiffened by braces, in order to decompose the action of the vertical weights thrown upon the respective temporary structures intended to support them. It thence follows, from the peculiar nature of the resistances of timber to permanent efforts, that the various pieces of a centre should be made to receive their ultimate strains in a direction vertical to their length, as far as it is possible so to combine the framing; because, from the mere fact of the elasticity of the kinds of wood usually employed, the outline of the centre would be liable to deformation under the action of the permanent load, if that load should act either transversely or in a markedly inclined direction to the fibres of the wood employed. Even the Romans themselves seem to have been aware of this law, for they evidently made the centres of their arches of the very smallest possible span, in order to reduce the thrusts upon those centres to the most direct vertical action; and in the erection of the Pons Celsius of Rome, and in the Pont du Gard in France, it is evident that every advantage was taken of the dynamical resistance of the springing of the arches, to diminish the effort thrown upon the wooden framing intended to support the weight of the vault in the intermediate part. In both these cases it would appear, from the projections left upon the voussoirs, that the centres were made to rest upon the stones laid with an inclination of about 30° to the horizon, an inclination at which the friction upon the bed was only just balanced by the effects of gravity; and indeed it is more than probable, from the constructive details still to be observed in these bridges, that the Roman engineers adopted nearly the same modes of proceeding which are even now followed by practical builders in the execution of similar works. Amongst other facts to be gathered from the remains of antiquity which still survive in a tolerably perfect state, it would appear that even the modern sub-classification of close-boarded centres and of laggings was known to the Romans; and in the subsequent part of this article we shall have occasion to refer to the practical distinction between the two.

In small arches it is, of course, easy to make the centres of sufficient strength to resist the superincumbent weights, without producing any change of form in the outline of the vault; but in large arches the centres are so much exposed to vary in their outline, that it has been found advisable to admit at once the distinction between the flexible and the inflexible centres; and, in the cases of both these varieties, to further subdivide them into centres designed to receive the whole arc from the springings to the crown, and into the centres having intermediate supports,—or, in other words, into entire or into partial centres.

At the present day, the flexible centres used by Perronnet, in the construction of the bridge at Neuilly, are almost entirely abandoned; because the shape of the intrados of an arch, raised upon such a centre, must inevitably be exposed to changes of the most extraordinary and irregular nature. In fact, a centre of this description must always be liable to change its form, from the mere pressure of the voussoirs which are progressively added, and the only mode of obviating this inconvenience would consist in weighting down those parts of the centre

Centre of Neuilly Bridge.

which did not immediately support the load. The success of any such operation must of course be always equivocal, and the great subsidence which took place in the masonry erected upon the centres of the Neuilly Bridge, may be referred to as proving the danger attending the application of the particular centre there used. In the article

BRIDGE, this has been already alluded to; and the extent of the settlement recorded in that case must be considered to be the most marked condemnation of the system adopted; but it may also be observed that in previous experiments the same results had been obtained, as in the case of the old bridge of Moulins over the Allier, erected by Mansard. The flexibility of centres like those used by Perronnet and Mansard, in the cases thus cited, arises from the perfect freedom of the timbers of which they are composed to move upon one another; but, by the same rule, it follows that precisely in proportion as the haunches are loaded in an arch of this description, the centre must rise at the crown, unless some artificial means be adopted to keep it from rising. As it is impossible to regulate these movements, it follows that the use of flexible centres must be abandoned in all cases where it is desired to secure the regularity of the curvature of the arches, and a rigid system of framing must be introduced, which, as before said, may either be supported upon the springing of the arches themselves, or upon intermediate points of support in the opening they are designed to span. In some cases centres are framed, designedly, to be supported in the commencement upon the springings only; and to be subsequently strengthened by intermediate struts, inserted during the progress of the work; and there appear to be really some important advantages in this system, for the centres can, under it, be more easily slackened than when there are no intermediate supports.

In the more modern centres, such as those used for the London and Waterloo bridges, one of the most serious sources of danger (namely, that arising from the number of butt joints) which occurred in the earlier descriptions of centres, was obviated by the use of cast-iron shoes; and, as will be observed, the timbers are made to support strains

Centre of London Bridge.

Centre of Waterloo Bridge.

acting principally in the direction of their length. The cast-iron shoes also acted as ties to the whole of the framing, and thus prevented the centre from rising in any dangerous manner at the crown. But even in these cases it was necessary to carry up the arches evenly on either side, and to weight the centres temporarily at the summit.

In the case of the great Chester bridge, the largest span of any stone bridge executed of late years, the engineer, Mr. Harrison, supported the centre by means of four temporary piers erected in the water way

Centre of Chester Bridge.

of the river; and he was thus enabled to place the struts of his framing so as to receive the whole of the weight thrown upon them, in a direction but slightly oblique to their axes. Telford, in erecting the Gloucester bridge, did somewhat the same thing, for he supported his

Centre of Gloucester Bridge.

centres upon intermediate piles driven into the bed of the river; and the engineer of the great bridge over the Dora Riparia, at Turin, introduced an intermediate support in the modification of the Neuilly centre he employed. In fact the danger of subsidence in a centre of large span must be so great, that the greatest precautions must be adopted to guard against it; and as such precautions necessarily involve great money outlays, it must evidently be preferable to diminish the necessity for them by diminishing the opening to be temporarily spanned. The execution of such triumphs of engineering skill as the centres of London Bridge, is too costly to be repeated oftener than may be absolutely necessary.

In Fontana's great work, published at Rome, 1694, 'Il Tempio Vaticano,' the centres used by Michel Angelo for the execution of the dome, and of the long vaults of that building, are very faithfully given in the plates opposite pp. 320 and 412; and they may still be referred to as models notwithstanding the progress of modern science, and even notwithstanding Dr. Robison's faint praise. In the construction of part of the dome of the Pantheon of Paris, Rondelet made every ring of voussoirs complete in itself, so that the centre he employed, which is given in his 'Art de Batir,' Paris, 1843, had but, comparatively speaking, little to do in supporting the weight of the masonry, in those portions at least; but when the rings of voussoirs were interrupted to receive the openings of the windows, a more complicated centre was required. The reader would do well to study this portion of Rondelet's work, for it contains some of the most valuable practical and scientific reasoning, on the action of arches upon their centres, to be found in any existing work on architecture; excepting,

perhaps, the first volume of Robison's 'System of Mechanical Philosophy,' Edinburgh, 1822.

It has been already mentioned [BRIDGE], that the system of supporting the extremities of centres had been, until a very recent period,

Centre of Viaduct on Grand Junction Railway.

to place them upon a series of wedges, which were driven back when it was thought advisable to release the arches; and in the cases of London, Blackfriars, and Waterloo bridges such wedges were used. But it often happens that the grains of the woods used for the wedges, and the inclined ways, are driven by the superincumbent load into one another to such an extent that it is not possible to move them; and under such circumstances, it has occasionally been found necessary to cut away the points of support of the centres, and to let them fall, perhaps, abruptly. Even when the wedges move, the blows they require are likely to jar the masonry; and it was with a view of obviating this serious practical evil that the use of the sand-bags, described as having been applied on the Tours and Bordeaux Railway bridges (in the 'Annals des Ponts et Chaussées'), was introduced. It seems, however, that there are occasional difficulties attending the discharge of the sand from the vessels placed at the feet of the centres; and as under any circumstances it is preferable to employ centres with intermediate points of support, added subsequently to the placing of the great framing resting upon the springings, it may be sufficient to trust to the loosening of the centres by the gradual removal of the said intermediate supports.

In small centres, in centres for brick, concrete, rubble, or groined arches, the frames, which are usually spaced at intervals of about five feet, are covered with what is technically called "close boarding;" in centres for large openings, wherein ashlar masonry is employed, the courses of stones are supported upon "laggings," placed at right angles to the axis of the structure. In both cases precautions must be taken to prevent any lateral movement of the frames or trusses by the introduction of a system of cross braces, which should be designed in such wise as to distribute the partial weights in as general a manner as possible over the whole system of framing.

In addition to the works quoted above, see Tredgold's 'Elementary Principles of Carpentry,' Lond., 1840; Emy, 'Traité de la Charpenterie,' Paris, 1841; Kraft, 'L'Art de la Charpente,' Paris, 1805; Silloway's 'Handbook of Modern Carpentry,' New York, 1858.

CENTIGRADE means divided into one hundred degrees. The centigrade thermometer of Celsius divides the interval between the freezing and boiling points into 100 degrees. Thus 100 centigrade degrees are equivalent to 180° of Fahr.; and to turn the reading of a centigrade thermometer into that of Fahrenheit, proceed as follows:—Multiply by 2 and 20, subtract, divide by 10, and add 32. Thus for 78° centigrade—

$$\begin{array}{r} 78 \\ \times 2 \\ \hline 156 \\ \times 20 \\ \hline 1560 \\ \hline 1404 \dots 1404 \\ \quad 32 \\ \hline \end{array}$$

172.4 Fahr.

CENTRAL CRIMINAL COURT. This is a court established in 1834, by 4 & 5 Wm. IV. c. 36, for the trial of treasons, murders, felonies, and misdemeanours committed within the city of London and county of Middlesex, and parts of Essex, Kent, and Surrey. By s. 22

the court is authorised to try offences committed on the high seas and other places within the jurisdiction of the Admiralty of England, and by the 19 & 20 Vic. c. 16, the court of Queen's Bench may order certain offenders to be tried at this court. The justices of the peace were prohibited by the Act from trying at their sessions persons charged with capital and a variety of other offences, alleged to have been committed within the jurisdiction of the Act; but the restriction was repealed by the 14 & 15 Vic. c. 55. This jurisdiction comprises the whole of Middlesex; in Essex, the parishes of Barking, East Ham, West Ham, Little Ilford, Low Layton, Walthamstow, Wanstead, Woodford, and Chingford; in Kent, Charlton, Lee, Lewisham, Greenwich, Woolwich, Eltham, Plumstead, St. Nicholas's Deptford, that part of St. Paul's Deptford which is within Kent, the liberty of Kidbrook, and the hamlet of Mottingham; in Surrey, the borough of Southwark, the parishes of Battersea, Bermondsey, Camberwell, Christchurch, Clapham, Lambeth, St. Mary Newington, Rotherhithe, Streatham, Barnes, Putney, that part of St. Paul's Deptford which is within Surrey, Tooting, Graveney, Wandsworth, Merton, Mortlake, Kew, Richmond, Wimbledon, the Clink Liberty, and the district of Lambeth palace.

For all purposes under the Act the above district is considered as one county, and in all indictments and presentments the venue runs "Central Criminal Court, to wit."

The judges of the Central Criminal Court are appointed by the Act to be any two or more of the following persons; the lord mayor for the time being of the city of London, the lord chancellor or the lord keeper of the great seal, and all the judges for the time being of his Majesty's courts of King's Bench, Common Pleas, and the Exchequer, the chief judge and the two other judges in Bankruptcy, the judge of the Admiralty, the dean of the arches, the aldermen of the city of London, the recorder, the common serjeant, the judges of the sheriff's court of the city of London for the time being, and any person or persons who hath or shall have been lord chancellor, lord keeper, or a judge of any of his Majesty's superior courts of Westminster, together with such others as his Majesty, his heirs and successors, shall from time to time name and appoint by any general commission. The power of selecting the judges from so extensive a list renders it unnecessary to issue a commission every time the sessions are held, and the period of holding the sessions is not interrupted when the judges of the courts at Westminster are absent on circuit. The sessions are held twelve times a-year at the Old Bailey and in the New Court adjoining, and the judges are usually two of the common-law judges and the recorder of the city of London. Before the Central Criminal Court was established, sessions were held at the Old Bailey eight times a-year for the trial of offences committed in Middlesex, and bills were returned by a grand jury sitting at Clerkenwell under the jurisdiction of the county magistrates. Offences committed at Southwark or Greenwich, both of which places may be regarded as parts of the metropolis, were, in the case of Southwark, tried at Guildford, Kingston, or Croydon, as it might happen, and from Greenwich an offender was sent for trial to Maidstone. From the great amount of population, the calendars were necessarily so heavy that a winter assize became necessary for parts of the Home Circuit; but it was still better to place the whole metropolitan district under one jurisdiction, and to have a gaol delivery every four or five weeks.

Jurors are summoned by the sheriffs of the city of London and of the counties of Middlesex, Essex, Kent, and Surrey, according to the parts of the district in which they reside. The juries are selected from London alone; or from Middlesex, and the parts of counties which are within the limits of the act; or from both indiscriminately. Jurors from Essex, Kent, and Surrey, who have served upon any jury at the Central Criminal Court are exempted, for the ensuing twelve months, from serving upon any jury in any court (except the sessions of the peace) held in the county in which they reside.

By the Stat. 7 Will. IV. and 1 Vict. c. 77, the practice of this court was assimilated to other courts of criminal judicature with respect to offenders liable to the punishment of death; and by the 9 & 10 Vict. c. 24, indictments may be preferred before the grand jury of the Central Criminal Court in the same manner as before any other grand jury.

The area over which the jurisdiction of the Central Criminal Court extends is about the 130th part of the area of England and Wales, but the population is between one-seventh and one-eighth of that of England and Wales. Nearly as many prisoners are annually tried at the Central Criminal Court as at all the county assize courts in England and Wales.

CENTRE, from the Greek *κέντρον*, a sharp point. This word, by its successive introduction in one sense and another, has become a generic term for any point of a figure or solid body, such that the whole of the figure or body might be collected into that point, without any alteration except in some respect or other which is specified. It is, in fact, an average point, as the following species of it will show:—

1. *Centre of Cavity.* [METACENTRE.]
2. *Centre of a Curve.*—The point where any two diameters of the curve intersect one another. When all the diameters intersect at this point, Newton calls it the *general centre*.
3. *Centre of a Dial* is the point where the gnomon or style, which is generally parallel to the axis of the earth, intersects the plane of the dial.

4. *Centre of Figure.*—If any number of points be situated in given positions with respect to a plane (A), their average perpendicular distance from the plane is common to all the points of a second plane (B), parallel to (A). If two other planes (A') and (A'') be taken, and if (B') and (B'') be planes distant from them by the average distances of the points, then (B), (B'), and (B'') will meet in a point which is obviously distant from the three planes by the several average distances of the points. And it is proved, by the application of algebra, that the point thus determined is also distant from any other plane whatsoever by the average distance of the points; whence it may be called the *centre of figure* of the points. It is usual to call it the *centre of gravity*, which it is on one particular supposition only, namely, that the points are supposed to have *equal weights*.

A solid figure cannot be supposed to be made up of points; but if it be divided into a number of equal elementary portions, and if one point be taken in each, and the centre of figure then found in the manner just described, the principles and processes of the integral calculus will determine the centre of figure of the portion of space within the limits of the whole solid. This, as before, is only the centre of gravity, on the supposition that the solid is of uniform density throughout.

The centre of gravity may be made useful in finding the contents of surfaces and solids formed by revolution, as follows:—

i. If an arc revolve round an axis the surface traced out is equal to a rectangle, one side of which is equal in length to the arc, and the other to the arc of a circle through which the centre of gravity of the revolving arc passes.

ii. If an area revolve round an axis, the volume of the solid thus generated is equal to a cylinder or prism which has the area for its base, and the arc traced out by the centre of gravity of the area for its altitude.

These propositions are the foundation of what has been called the *centro-baryc* method.

5. *Centre of Force or Attraction.*—That point to which all the parts of a system are attracted by virtue of the force emanating from it, or inherent in it.

6. *Centre of Friction.*—This is a term now fallen into comparative disuse. It is that point in the base of a body on which it revolves, into which, if the whole surface of the base and mass of the body were collected, and made to revolve about the centre of the base, the angular velocity destroyed by friction would equal the angular velocity destroyed in the body by its friction in the same time.

7. *Centre of Gravity.*—This is the point at which the weight of the body being collected, the equilibrium of the body and of the system (if any), of which it forms a part, will not be disturbed.

8. *Centre of Gyration.*—This term, which is almost peculiar to English mathematicians, has the following meaning: it is the point at which, if the whole of the matter in a body were collected, given forces would produce the same angular velocity of rotation in a given time as they would do if the particles of the body were distributed in their proper places. This centre is of course dependent upon the axis of rotation as well as the form, &c. of the body; every axis which can be chosen has its own centre of gyration.

9. *Centre of a Lens.*—When the surfaces of a lens are concentric, the centre is, of course, equidistant from each of them; but when they are of different curvatures, the centre of the lens is nearer to one vertex than to the other, by as much as the radius of curvature of the former is less than that of the latter.

10. *Centre of Oscillation.*—The point in which the whole of the matter must be collected, in order that the time of oscillation may be the same as when it is distributed.

11. *Centre of Percussion.*—That point of a revolving body which would strike an obstacle with the same force as if the whole of the matter were collected in it.

12. *Centre of Pressure.*—The point at which the whole amount of pressure may be applied with the same effect as it has when distributed.

13. *Centre of Suspension* of a pendulum or other vibrating body having an angular velocity round a fixed axis, is convertible with the centre of oscillation, and hence is the point by which the body must be suspended in order to vibrate in the same time as if suspended by its centre of oscillation.

14. *Centre of Symmetry.*—That point in a figure or body round which the parts of it are similarly disposed, or have the same shape, size, &c., on each side. For methods of finding these several centres, see GRAVITY, &c., CENTRES OF.

In old writers, from the earliest periods, the term *centre* is used in the sense of a supposed centre of the universe, which it was imagined must coincide with the geometrical centre of the earth. And it was supposed to be a most obvious principle that all bodies must fall to this centre, which being a notion derived from the observation that all bodies fall towards the centre of the earth, was made an argument in favour of the stability of the latter. Even Copernicus has a notion of the existence of such a centre, or *medium mundi*, which, however, he places in the sun, while others consider one of the Pleiades to be the point in question. It is hardly necessary now to say that there is no evidence whatever for the existence of any centre of the universe, that is, of any point which must necessarily remain fixed; but so well

established was this notion in former times, that it was supposed even if the earth were to be annihilated, this centre would still exist with all its properties.

CENTRIPETAL and CENTRIFUGAL FORCES, forces which urge a body to *seek* (petere) or to *avoid* (fugere) a centre; in more modern language, attractive and repulsive forces. [ATTRACTION, REPULSION, FORCE, GRAVITATION, &c.]

We intend here to confine ourselves to the term *centrifugal force*, in one particular sense in which it is used in mechanics and astronomy, because it involves a point which is frequently mistaken. The term force, as used in mechanics, implies simply any cause of motion which is external to the matter moved; and the terms accelerating force, as well as retarding force, are used with reference to the velocities of bodies, and without reference to their masses or weights. So long as velocity remains unaltered, there is neither accelerating nor retarding force; when alteration of velocity begins, then we may say that force begins to act, for all we know of force is implied in the words, "cause of acceleration or retardation." Again, owing to the convenience of words implying causation, it is usual to give the name *inertia* to that property of matter by which it maintains its state, either of rest or motion, unless acted on by other matter. And since the state of matter left to itself is either that of rest or of uniform motion in a straight line, every other species of motion, of what sort soever, is an effect of force from without; which assertion is verified in every instance in which it can be tried.

Suppose we fasten a string to an immoveable obstacle, such as a post, and pull it, say with a force of a hundredweight. It may not at first sight appear proper to say that the post also pulls the string, because we may not be able to conceive the latter acting, but only resisting. Nevertheless, the part which the post sustains, call it action or resistance, is still the equivalent of a force, for if it were removed, and another hand applied to the other end of the string, that hand must also pull against the first with a force of a hundredweight before the counteraction of the moving tendency of the first pressure is supplied. And in calculating the numerical effects of pressures, the equations of motion can take no cognisance of the cause of the pressures, but only of their amounts; whence it will arise that the effect, say of the resistance of an immoveable obstacle, may enter an equation in precisely the same manner as a physical attraction [ATTRACTION], a muscular effort, or any other mode of accelerating or retarding velocity.

Next, it must be remembered that no alteration whatever of the effect of inertia can be produced without force of some kind. Let us now suppose a small bullet attached to a string, which string is fastened to a point upon a table, friction and the resistance of the air not being supposed to exist. Let the bullet be placed in a state of revolution round the fixed point by means of the string, and with a given velocity. It will continue to revolve round with the same velocity, and the string will be stretched by a pressure depending upon the mass of the bullet and its velocity. The reason of the permanence of the velocity is contained in a proposition which is demonstrated in mechanics, namely, that forces applied to a material point in the direction perpendicular to that of its motion cannot change its velocity, but only its direction. If, for instance, a hand could apply pressure to a moving point on a table, by means of a string, so adroitly as always to keep the pressure perpendicular to the direction of motion for the time, the whole amount of the pressure might be varied so as to make the point describe any curve, but always with the same velocity as at the outset. Now, in the present case, the bullet must describe a circle, and the direction of the string, in which the retaining pressure acts, is always perpendicular to the tangent of the circle, being always a radius. This pressure of the string must be caused by an effort to escape on the part of the bullet, arising from its tendency to continue its motion in the direction of the tangent. This is the centrifugal force, and does not arise from any tendency which the body has to fly from the centre, but from this circumstance, that there is in the motion above described a constrained approach to the centre, or rather a constrained continuance at the same distance from the centre, such as would not exist in the motion of the bullet uninfluenced from without.

The centrifugal force is thus measured: suppose, for instance, the velocity of revolution in the circle to be 8 feet per second, and the radius 10 feet. Divide the square of the velocity by the radius, or divide 64 by 10, which gives 6.4. Then the pressure is such, that were it to take the place of the earth's attraction, the bullet, being allowed to fall, would, at the end of one second, have acquired a velocity of $6\frac{4}{10}$ feet per second, instead of $32\frac{1}{2}$, which is the case with bodies falling freely to the earth. And if we ask what weight must be hung to the string, so that it may receive the same pressure as when constraining a bullet of two pounds in weight to move at 8 feet per second in a circle of 10 feet radius, the answer is, such a proportion of the weight of the bullet as $6\frac{4}{10}$ is of $32\frac{1}{2}$,

$$\text{or } \frac{6\frac{4}{10}}{32\frac{1}{2}} \times 2 \text{ pounds, or on } \frac{384}{965} \text{ of a pound.}$$

If then this latter weight, hung at its end, would be the utmost the string would bear without breaking, then any accession of velocity in the preceding motion would also break the string.

We now take the case of one of the planets moving in the curve AP

about the sun at S, and attracted towards the sun, so that if reduced to rest for a moment at P, it would immediately begin to descend towards S. It must always appear to one not used to consider these subjects, that this attraction being perpetually exerted must at last make the planet fall into the sun. But suppose for a moment the attraction removed, so that the planet would pursue its course along PT. Prevent this by an inextensible string SP, in which case the planet will proceed in the circle PV, not with the whole velocity with which (but for the string) it would have proceeded along PT, but with a part, as follows:—Let PT be the length which would be described in a second, draw PY perpendicular to SP, and complete the rectangle PXTY. Then the velocity PT might be produced, if the string were not there, by an instantaneous communication of the two velocities PX and PY in these directions. But when the string is supposed, the communication of

such an impulse as would produce PX has no effect except an instantaneous tension of the string, which is supposed capable of resisting it. There remains only PY, which would produce what has been before called the centrifugal force.

Now, if the string were not there, there remains the body P, with the same tendency to recede from the centre implied in its having the velocity PY, and with the effect, which would be counteracted by the string, entirely uncounteracted. If then we look at the *paracentric* motion only, or the manner in which SP is lengthened or shortened, independently of the angular motion, we have, 1. the paracentric velocity PX actually existing; 2. the attraction of S in the direction PS; 3. the tendency to recede from the centre arising from the velocity PY. The alteration of the first is not due to the second or third alone; if (2) exceeds (3) the velocity PX is diminished in the instant next following the body being at P; if (3) exceed (2) it is increased.

To realise the supposition above alluded to, namely, that the attractive force must bring the body P to the centre at last, we must put that force in a situation to act unopposed. Imagine a string which shortens as the body approaches the centre, so as always to remain stretched; and also suppose the attractive force to act, the effort to proceed in the tangent of the circle being destroyed by the string, and we have the case which is really supposed in the above mistake, for want of considering the centrifugal force.

The centrifugal force always (whatever the attraction may be) varies as the inverse cube of the distance, while the attractive force varies as the inverse square. Consequently if the revolution ever bring the body to 1-10th its primitive distance, the attraction is only 100 times as great as at first, while the effort to recede is 1000 times as great. Hence a very little knowledge of algebra will make it apparent that however much the external attraction may at first exceed the centrifugal force, there must come a point of approach to the centre at which the latter begins to exceed the former. And hence the alternate approach and recession of the planets to and from the sun. Let AZMPNV be the ellipse of a comet's orbit (we have

drawn it too elongated for that of a planet), A and P the aphelion and perihelion, AP the axis, and MN a perpendicular to it. Let the planet be projected at A with the necessary velocity: then from A to M the attraction exceeds the centrifugal force, and velocity towards the centre is created, as instanced by ZQ in the figure at Z. At M the attractive and centrifugal forces are equal, and from M to N the centri-

fugal exceeds the attractive, so that between M and P the velocity towards the centre is destroyed, and from P to N velocity from the centre is created. After N the attraction is again in excess, and between that and A the velocity from the centre is destroyed; after which the succession recommences.

Some readers may perhaps not find it easy to conceive how the centrifugal effect should exist, when the pressure of the string, which it appears to counterpoise, is not present. On which we must observe that the string does not make this effort to recede, but destroys its effect. If it is clear that there must be a pressure on the string in the first illustration, it is because, under the circumstances, there is a force to cause that pressure already existing. There are numerous experiments in illustration of centrifugal force: take a tube, for example, and place a bullet inside it; let the tube be then put into a state of rotation round one end, and the bullet will be projected straight from it. The governor of a mill or steam-engine is an instance in which this effort to recede is made useful. But the largest scale on which the centrifugal force becomes visible is in the alteration of the time of oscillation of a pendulum in going from one part of the earth to another. Let A be the point of suspension of a pendulum P, and PM

the line drawn through it perpendicularly to the earth's axis, so that the angle APM is the latitude of the place. The motion of the earth carries the pendulum round in a circle of which PM is the continuation of the radius, so that there should be a slight action on the pendulum, such as should result from a pressure in the direction PM. Resolve this into PQ and PZ; the second will alter the position of equilibrium of the pendulum, the first will counteract a small part of the weight. The second will never be made visible; nor the first, except in comparing the number of oscillations of the same pendulum in different places. For the weight of the pendulum being differently lessened in different places, but the mass always remaining the same, the accelerating force is altered. For the law of the alteration, and the history of its discovery, see PENDULUM.

CENTUMVIRI. [JUDEX.]

CENTURION. A centurion in the Roman army was the commander of a centuria, a term which we cannot conceive to have originally signified anything except a hundred; but there is no ground for supposing that the word centuria contains the elements of the word "viri," men. The term centuria was also applied to a hundred jugera of land; and Varro ('L. L.' v. 35) observes that the name was kept after the centuria contained two hundred jugera.

A centuria, as a division of an army, signified a number of men under the command of a centurio. The form of the word centurio is the same as that of the word curio. Niebuhr has endeavoured to show that the centuria originally consisted of thirty men ('Roman History,' vol. i. 471, iii. 100, Eng. Transl.) When the Roman legion contained thirty manipuli and sixty centuries, the number of the centurions would be sixty; but as the number of the legion was not a fixed number, we must suppose that the officer called a centurion had at various times a varying number of men under him.

The passage in Livy (xlii. c. 32, &c.) seems to show that the centurions were appointed by the military tribunes. But Polybius, in the fragment of his sixth book (c. 24), states that in his time twenty men were selected from the respective bodies of the hastati, principes, and triarii, who composed a legion: none were selected from the velites, or light troops, who were distributed among the hastati, principes, and triarii in just proportion. Polybius calls the Roman centurion *taxisarchus* (*ταξιάρχος*), which is a translation of the Latin phrase "ordinem ducere." There were two centurions to each of the divisions, or manipuli, as the Romans called them; and he that was first chosen commanded the right of the manipulus, and the other the left. Each manipulus had its standards, which were carried by two of the bravest and strongest soldiers, who were appointed by the centurions. The centurion who was first chosen was called *primipilus*, and was a member of the general's council: he was the first centurion of the first manipulus of the triarii, and he had the care of the eagle.

The pay of the soldier in the infantry, besides food and clothing, is stated by Polybius at two oboli a day, and double to the centurions. The obolus is a sixth part of the Attic drachma, or one-sixth part of 9*d*. This would therefore make the pay of a centurion about 16*s*. a month; by the time of Domitian it had been increased tenfold.

The duties of the centurions were to command their several manipuli. They received their orders from the tribunes of the legion, who received theirs from the commander of the army, whom they visited

every morning to receive their orders, which they then gave to the centurions. They also superintended the soldiers when they were engaged in the military works, such as castrametation. They had also to go round to inspect the watches; at least this is stated as among the duties in some passages of the Latin writers. The badge of office was a stick made of the stock of a vine (*vitis*). The speech of the centurion Sp. Ligustinus in Livy (xlii. 34), presents a lively picture of the laborious services of a Roman soldier who had worked his way up to the rank of *Primipilus*.

The centurions had defensive armour, a shield, an iron helmet with a crest placed transversely to distinguish them from the soldiers. They had also a mark (*signum*) on their helmet, probably to denote the centuria or cohort to which they belonged. ('Vegetius,' ii. 13; and the Notes of Stewechius.)

The granting of temporary leave from military service to the soldiers (*vacatio*), which is sometimes reckoned among the privileges of the centurions, was only an abuse that got established at a late period. It appears to be first mentioned in the beginning of the reign of Tiberius (Tacitus, 'Ann.' i. 17). However, the practice had become so far established that Otho thought it prudent to pay the centurions out of the imperial treasury (*fiscus*) such amounts as they had been in the habit of receiving from the soldiers on the account of the *vacationes*. Retired centurions had pensions: Suetonius mentions that Caligula reduced them to 6000 sesterces, or about 45*l*. per year.

Under the empire it seems that the centurionships were generally given as a matter of favour and patronage.

CEPHALOTE. This name was applied to a substance found in the brain of man, but which has more recently been proved to be a mixture of cerebrate of lime or soda with traces of albumen and of oleophosphoric acid.

CEPHEUS, a constellation, surrounded by Cassiopeia, Ursa Minor, Draco, and Cygnus, comes on the meridian at midnight in the middle of August, and at eight o'clock in the middle of October. A line drawn from the bright star in Cygnus to the Pole Star will be nearly bisected by α and η of this constellation. Cepheus, the King of Ethiopia, was the husband of Cassiopeia and the father of Andromeda, and was placed in the heavens, according to Hyginus, that no one of this remarkable family might be absent. He is represented in old plates as a man with a tiara on his head, kneeling on one knee, and with his arms extended.

The following are the principal stars in this constellation:—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
η	3	7220	4
α	5	7416	3
β	8	7493	3
ϵ	23	7778	4
δ	27	7848	4
ι	32	7967	4
γ	35	8238	3

CERAMIC ART. [PORCELAIN; POTTERY.]

CERASIN is that part of the gum of the cherry-tree which is insoluble in cold water. It is probably some transitional form between starch and gum.

CERATES, the name given to certain combinations of wax with other substances, which are used as external applications in the treatment of various surgical cases. They are of a degree of consistence intermediate between that of plasters and that of ointments; and, according to the nature of the materials united with the wax, are capable of serving different ends. They may be emollient, when applied to inflamed or chapped surfaces, or stimulating, when applied to indolent ulcers; and in the case of wounds or abraded skin are useful in excluding the air, and preventing the dressings from adhering.

CERBERUS, the watch-dog of the infernal regions, the offspring of Typhon and Echidna. Homer mentions him simply as the dog of Hades. He is first named Cerberus by Hesiod, who speaks of him as having fifty heads; according to Horace, he had one hundred; the ordinary account gives him only three, and this number, which corresponds to the triple form in which Geryon and Hecate appear, points to the usual phenomenon in the elementary worships of ancient Greece, in which a power of the nether world was also a terrestrial and celestial divinity. The Chimæra was another monster of the same kind. Cerberus was also the name of a serpent which infested the neighbourhood of Cape Tænarus. The word probably signifies "dark;" Cerberian occurs as a synonym for Cimmerian in Hesychius. Nicander applies it as an epithet to a toad. (Dahler, *Lex. voc. peregrin.*; Steph., *Thes.* ed. Lond., i. p. xxxii.)

CEREBRIC ACID, formerly called cerebrin, is a substance said to exist in the fatty matter of the brain. It is accompanied by another acid, the *oleo-phosphoric acid*, which is supposed to be united to a compound radical *cerebroleine*, in the manner of the fatty acids. These substances are of a very doubtful nature, and the chemistry of the nervous system is at present in a very imperfect state.

CEREBRIN. [CEREBRIC ACID.]

CEREBROLEINE. [CEREBRIC ACID.]

CEREBROTE. A name applied to a substance obtained from the human brain, but which is now known to be merely a mixture of cerebrie acid, cerebrate of lime, cerebral albumen, &c.

CERENE ($C_{54}H_{84}$), is a solid wax-like body, derived from bees'-wax. It is now believed to be identical with paraffin.

CERES. [DEMETER.]

CERES, one of the group of small planets, but the largest except Vesta, which revolve between Mars and Jupiter.

CEREVISIÆ FERMENTUM, *Medical properties of.* Yeast, barm, or zumin has been known as long as fermented drinks, being the active or exciting agent by which they are formed out of saccharine juices. [WINE.] The intimate nature and mode of action of ferments have been studied with great care by Turpin, Cogniard Latour, Schwann, Liebig, M. Rousseau ('Comptes Rendus,' No. 17, April 24, 1843), and Bouchardat ('Comptes Rendus,' and 'The Chemist,' vol. v. p. 401.) These observers have established numerous differences in ferments; but it is to the common yeast of beer-brewers that the following observations apply. Its presence, or that of any gluten-like material, excites in saccharine fluids an intestine motion, by which, if there be sufficient yeast, the sugar is resolved into alcohol and carbonic acid. It is while this change is taking place that yeast is deemed most useful. It is employed both internally and externally. In the former case, the malt which supplied the saccharine principle has often been given along with or instead of it, under the name of malt or wort. It was highly commended by Dr. Macbride, in the treatment of scurvy, before the utility of lemon-juice was generally recognised; and some recent writers have given instances of its advantageous employment. The objection to its use is, that it generally increases the diarrhoea; but this is not invariably the case. It has been strongly recommended by Dr. Stoker of Dublin in typhus fever; and enemata made with it have proved useful against typhoid tympanites. All this is extremely probable, from the explanation given by Liebig of the manner in which ferments promote the digestive process. ('Animal Chemistry.')

The yeast poultice is an excellent application to putrid and gangrenous ulcers, with offensive discharge and unhealthy granulations. It must be renewed every six hours. Its beneficial influence is not owing solely to the carbonic acid gas evolved, as the same good effects do not follow when a stream of carbonic acid gas is directed on the sores. Dr. Stephen Williams of the United States strongly recommends a poultice of fine malt and boiling beer, with yeast spread on the surface, applied frequently in the twenty-four hours. Under its use the offensive odour and discharge cease, the granulations become firm and healthy, and the healing process goes on steadily. It is expedient to continue its use for three or four days. ('American Journal of Medical Science,' May, 1832, p. 38.)

German yeast, which is in a dry state, and begins its action on being moistened with water, has the advantage over common yeast of being more rapid in its development and effects. When used, it must be more frequently renewed.

Yeast has recently been recommended in the treatment of boils, which have prevailed epidemically; but there can scarcely be a doubt that well-fermented porter is as beneficial, and more grateful.

CERIC ACID. An acid body obtained by the action of nitric acid upon a wax-like substance found in cork. Its exact composition is not known.

CERIC ALCOHOL. [CEROTIC ACID.]

CERINE. [BEES'-WAX.]

CERIUM, ORES OF.—1. *Cerite*, found near Riddarhittan, in Sweden; it occurs anorphous. Its colour is pale dull red, sometimes grayish, and its streak is white; its lustre is resinous, slightly translucent, and sufficiently hard to give sparks with steel, or 5.5. Sp. gr. 4.912.

According to Hisinger, it consists of

Silica	18
Peroxide of cerium	68.59
Peroxide of iron	2.00
Lime	1.25
Water and carbonic acid	9.60
	99.44

Dr. Thomson considers it as a hydrous silicated peroxide of cerium.

2. *Cerine*, found as above; occurs massive and in imperfect crystals. Colour brownish-black, streak brownish-gray opaque, with an imperfect metallic lustre. Hardness, 5.5 to 6.0. Sp. gr. 4.173. Composition according to Berzelius:

Silica	30.17
Oxide of cerium	28.19
„ iron	20.72
„ copper	.87
Alumina	11.31
Lime	9.12
	100.38

3. *Allanite*, found at Alluk, East Greenland. It occurs massive, and crystallised in the form of a doubly oblique prism. Fracture imperfect

conchoidal. It is opaque, with an imperfect metallic lustre. Colour brownish-black, streak greenish gray. Hardness, 6.0. Sp. gr., 4. It is composed according to Stromeyer, of

Silica	33.021
Protoxide of cerium	21.600
„ iron	15.101
„ manganese	0.404
Alumina	15.226
Lime	11.080
Water	3.000
	99.432

These are among the principal ores of cerium, but for an account of some others, consult Phillips's *Mineralogy*, and Dana's *Mineralogy*. See also Watts' *Memoir on Phosphocerite* in *Journal of the Chemical Society*, vol. ii. p. 131.

CEROLEIN. A soft fusible substance obtained from bees'-wax. It is probably a mixture, and not a distinct chemical compound.

CEROSIC ACID ($C_{96}H_{96}O_6$). A white crystalline acid produced by treating CEROSIN with potash lime.

CEROSIN, $C_{48}H_{48}O_2$, is a waxy substance found on the surface of the sugar-cane. It is not saponifiable.

CEROTENE ($C_{54}H_{54}$). A product of the dry distillation of Chinese wax. It is a white crystalline substance like paraffin with which latter body it is probably homologous.

CEROTIC ACID ($C_{54}H_{53}O_3 + HO$). This compound was discovered by Brodie as an ingredient of bees'-wax in a free state. It may be procured by dissolving wax in hot alcohol, and dissolving the residue deposited on cooling till its melting point rises to 162°. It is then purified by ether till its melting point is 171°, which is that of the acid. This substance was formerly called *cerine*. It has, however, acid properties, and combines readily with bases. It combines with oxide of ceryl, forming the cerotate of that substance, $C_{54}H_{55}O + C_{54}H_{53}O_3$, which is called *cerotine*. When heated with potash, it produces cerotate of potash and the hydrated oxide of ceryl, or *ceric alcohol* ($C_{54}H_{55}O, HO$). [BEES'-WAX.]

CEROTIC ETHER ($C_{54}H_{53}[C_4H_9]O_4$). The compound of cerotic acid with oxide of ethyl. It is a wax-like body.

CEROTINE. [CEROTIC ACID.]

CERTIORARI, in law, is a writ issuing from one of the superior courts, directing the judges or officers of an inferior court to transmit or cause to be certified (*certiorari facias*) records or other proceedings. The object of the removal is either that the judgment of the inferior jurisdiction may be reviewed by the superior court, or that the decision and the proceedings leading to it may take place before the higher tribunal. An instance of the former is where the convictions of magistrates or the judgments or orders of courts of quarter-sessions are removed by certiorari into the Court of Queen's Bench by way of appeal against their validity, in which case the decision which has previously been given is re-considered, and is either confirmed or set aside. An instance of the latter is where an indictment found against a peer by an inferior jurisdiction is certified or transmitted into the Court of Parliament or the Court of the Lord High Steward, in order that the further proceedings and the adjudication may take place before the proper tribunal. By this writ, indictments, with the proceedings thereon, may, at any time before actual trial, be removed from the assizes or quarter-sessions into the Court of Queen's Bench, as the supreme court of ordinary criminal jurisdiction. A certiorari for this purpose was formerly granted on the application of a prosecutor as a matter of right; but by 5 & 6 Will. IV. c. 33, it is enacted that no certiorari shall issue to remove indictments or presentments from inferior courts to the Court of Queen's Bench, at the instance of a prosecutor, without leave obtained from the court, as by a defendant, and by the same statute, whether removed at the instance of a prosecutor or of a defendant, the party removing must enter into a recognisance to pay the costs subsequent to the removal in the case of acquittal or conviction, as the case may be. The 16 & 17 Vict. c. 30, s. 4, has limited the removal of indictment by certiorari. After reciting that by reason of the establishment of a Court of Criminal Appeal, the removal of indictments by writ of certiorari is seldom necessary for the decision of questions of law, but is nevertheless sometimes resorted to for purposes of expense and delay, it enacts that no indictment except against bodies corporate, shall be removed into the Court of Queen's Bench, or into the Central Criminal Court, by writ of certiorari, either at the instance of the prosecutor or the defendant (other than the attorney-general acting on behalf of the Crown) unless it be made to appear by the party applying that a fair and impartial trial cannot be had in the court below, or that some question of law of more than usual difficulty and importance is likely to arise upon the trial, or that a view of the premises should be taken in respect whereof any indictment is preferred, or a special jury may be required for the satisfactory trial. In order to avoid the occurrence of frivolous appeals, it is usual in statutes which give summary jurisdiction to inferior tribunals to restrict, or altogether take away, the right to a certiorari. The removal of cases from the county courts is specially provided for by the statute 19 & 20 Vict. c. 108, s. 38.

CERULO-SULPHURIC ACID. [INDIGO; Sulphindigotic Acid.]

CERUSE. [LEAD, CARBONATE OF.]

CERVUS E'LAPHUS (Hartshorn), *Medical properties of.* The hart or stag is too familiar to require any description. The antlers shed annually yield the part used in medicine, called *Cornu cervinum*, the shavings or raspings of which are termed *rasura* or *ramenta*. These differ from the hollow horns of oxen, and approximate more to bones, from which they are distinguished by having less phosphate of lime and more gelatine. Merat-Guillot gives as the constituents: soluble cartilage (gelatine), 27.0; phosphate of lime, 57.5; carbonate of lime, 1.0; water and loss, 14.5. The gelatine is readily extracted by boiling water, and its abundance is such that one part to two of water, reduced by boiling to two-thirds or three-fourths, furnishes a consistent jelly. This is in general easily digestible, and suitable to convalescents. It may be flavoured with orange or lemon, and wine be added or withheld according to circumstances. This jelly mixed with equal parts of cow's milk is said by Dr. Thomson to be useful in irritations of the digestive organs of infants. The same good effect will often result from the addition of a small portion of lime water to the milk.

The phosphate of lime procured by incineration of hartshorn is ordered to be employed in preparing the Pulvis Antimonialis.

Hartshorn was formerly used as the source of ammonia; hence it was termed volatile spirit of hartshorn. [AMMONIA.]

CERYL ($C_{54}H_{55}$). The radical of ceric alcohol. [CEROTIC ACID].

CESSIO BONORUM, in the law of Scotland, is the name given to a process by which, as by the insolvency system in England, the estate of an insolvent person who does not come within the operation of mercantile bankruptcy is attached and distributed among his creditors. Both the nomenclature and the early practice of the system are taken from the Roman law. ('Dig.' 42, tit. 3.) According to the more ancient law, the person released from prison on a cessio bonorum was bound to wear a motley garment called the dyvour's habit. In later times this stigma became the penalty of fraud, and it was subsequently disused. Cessio bonorum exhibits, like the insolvency system in England, this important difference from mercantile bankruptcy, that the person who obtains the privilege is not discharged from his debts, but only from proceedings against his person for payment of past debts, his estate continuing to be liable to the operations of his creditors. In Scotland, however, the common law means of attaching a debtor's property are simple and effectual, and there does not appear to have been there the same inducement as in England to make the process for the distribution of the debtor's effects an instrument of their discovery. The Scottish system, moreover, cannot be used by the creditors as a means of compelling their debtor to distribute his estate. It is a privilege of the debtor, and being seldom resorted to except by persons in a state of destitution who are harassed by vindictive creditors, the improvement of the system has not been a matter of much interest either among lawyers or legislators.

CESSION. When an ecclesiastical person accepts a second benefice or dignity in the church, which is incompatible by law with that which he previously held, the latter is said to be void by cession. This avoidance takes place *ipso facto* upon the acceptance of the second benefice; and the patron may at once, without any sentence of deprivation in the spiritual court, and without any express resignation, present a new incumbent, and require his admission. By the statute 21 Hen. VIII. c. 13, s. 9, if a person, possessed of a benefice with cure of souls of the yearly value of 8*l.* or above, accept and take any other benefice with cure of souls, without a dispensation to hold both, the first is declared to be wholly void in law. But even if the first benefice be under the value of 8*l.*, and for that reason not within the statutory provision, it becomes void by the canon law as against the patron, in consequence of the acceptance by the incumbent of a second benefice or dignity. (Burn's *Ecclesiastical Law*, tit. *Avoidance and Lapse*; Blackstone, vol. i. p. 396.)

CESTUI QUE TRUST. [TRUST AND TRUSTEE.]

CETENE. [CETINE.]

CETIC ACID is, according to M. Heintz, one of the acids that, combined with oxide of cetyl [CETYL, OXIDE OF], form cetine [CETINE].

CETINE ($C_{64}H_{65}O_2$). The name usually given to the crystallisable matter which forms the greater part of the substance called spermaceti. In order to obtain it pure, the spermaceti must be treated with boiling alcohol, and the clear solution, on cooling, deposits cetine, which, if requisite, is to be purified by a second solution in, and deposition from, alcohol.

Cetine is white, crystalline, soft to the touch, and friable; it is nearly inodorous, is tasteless, and does not act upon litmus; it fuses at 120° Fahr. When distilled in vacuo, it is volatilised without change; but when heated in a retort in the usual way, it yields a liquid hydrocarbon called *cetene*, and ultimately a large proportion of a solid crystalline substance, *palmitic acid*, traces of charcoal remaining in the retort. One hundred parts of boiling anhydrous alcohol dissolve 15.8 of cetine; but when its specific gravity is .834, only three parts are dissolved. If one part of cetine, an equal weight of hydrate of potash, and two parts of water are digested at a temperature between 122° and 194° Fahr. for several days, a soap is formed which is different from other soaps, combined with an unsaponified fatty matter, which Chevreul calls *ethal*. [CETYL, HYDRATE OF.] When this soap is decomposed by an acid, the ethal is separated with the acids; 100 parts of cetine thus treated, give 60.96 parts of these acids, and 40.64

of ethal, the increase of weight amounting to 1.6. According to Chevreul the acids separated by and combined with the potash are margaric and oleic; Heintz asserts them to be stearic, palmitic, myristic, cocinic, and cetic; while the analyses of Stenhouse and Smith show cetine to be simply palmitate of cetyl. The products of the oxidation of cetine by nitric acid (cetanthylic, adipic, pimelic and other acids), are the same as those produced under the same circumstances from suet, wax, and other fatty matters.

CETRARIA ISLANDICA. [ICELAND MOSS.]

CETRARIC ACID—*Cetrarine* ($C_{36}H_{16}O_{16}$). A white crystalline acid, found in Iceland moss, and communicating to the latter its peculiar bitter flavour.

CETRARINE. [CETRARIC ACID.]

CETUS, the sea-monster, called Pistrix by Hyginus, and Orphus by some of the Greeks, is said to represent the monster which is going to devour Andromeda. It is situated below Pisces and Aries, and a bright star in the head, called Menkar (*a Ceti*), comes on the meridian at eight o'clock in the beginning of January. It is usually drawn with a fish's head, two paws in front, and a curled fish's tail. The following is a list of the principal stars:—

Character.	No. in Catalogue of Flamsteed.	No. in Catalogue of British Association.	Magnitude.
ϵ	8	62	3
β	16	196	3
η	31	332	3
τ	52	536	3
ζ	55	565	3
ν	59	618	4
ϕ	68	720	2
ρ	72	754	4
σ	76	781	4
δ	82	811	3
ϵ	83	815	3
γ	86	837	3
μ	87		4
π	89	847	4
α	92	949	2

CETYL ($C_{32}H_{33}$), an organic radical of the C_nH_{n+1} series, and therefore homologous with methyl, ethyl, amyl, &c. Like them, in compounds it takes the place of hydrogen or a metal. [ORGANIC RADICALS.] The principal terms only of the cetylic group of bodies will here be described; the most important, because the one from which all the others are directly or indirectly derived, is

Hydrate of cetyl ($C_{32}H_{34}O_2 = C_{32}H_{33} \left\{ \begin{smallmatrix} H \\ O_2 \end{smallmatrix} \right\}$); *cetylic alcohol*: *ethal*.—

Ordinary fats, when saponified with an alkali, yield certain acids, and the base glycerin. Spermaceti, however, when treated in the same way, yields certain acids and the base *ethal*. Both glycerin and ethal are alcohols, though belonging to different series and different classes; ethal containing a radical of the C_nH_{n+1} series, and of the monatomic class; that is, as seen by its formula, its radical replaces one atom of hydrogen in one double atom of water $\left\{ \begin{smallmatrix} H \\ H \end{smallmatrix} \right\} O_2$. Ethal, in fact, differs

only from ethylic alcohol, or ordinary spirit of wine, ($C_2H_5 \left\{ \begin{smallmatrix} H \\ H \end{smallmatrix} \right\} O_2$), in containing the radical cetyl ($C_{32}H_{33}$) in the place of the radical ethyl (C_2H_5).

The best method of obtaining ethal in a state of purity is to melt two parts of spermaceti and to gradually add to it one part of solid hydrate of potash broken up into very small pieces. The mixture should be well stirred during the operation, and when the whole of the potash has been added should be treated with water and slight excess of hydrochloric acid. The ethal and fatty acids are thus liberated, float on the surface of the aqueous liquor, and after being carefully removed by decantation are agitated with excess of hydrate of lime. A solid lime-soap is thus formed, from which the ethal may be separated by dissolving out with spirit of wine; the spirit distilled off and the residue digested in ether gives a solution from which the ethal may be obtained in a pure state by evaporation.

Ethal thus purified is a white, solid, crystalline mass. It melts when heated to 119° Fahr., and by very slow cooling is obtained in brilliant lamellar crystals. It has neither odour nor taste, is easily volatilised with vapour of water, and when pure may be distilled alone without undergoing decomposition. It is insoluble in water, but miscible in all proportions with alcohol or ether. When ethal is heated with anhydrous phosphoric acid, it is by dehydration converted into

Cetene ($C_{32}H_{32}$), a colourless oily liquid. Boiling point, 527° Fahr. Vapour density, 8.007. It may be distilled without decomposing, is insoluble in water, very soluble in alcohol or ether, has no action on test-paper, and burns with a pure white flame.

Sodium and potassium act upon hydrate of cetyl at a temperature of 212° Fahr., forming *cetylates*—

The soda salt, called also *oxide of cetyl and sodium*, is a yellowish-gray solid. It melts at 212° Fahr., and at 230° Fahr. is a clear liquid. Boiling water does not affect it; hydrochloric acid decomposes it into chloride of sodium and hydrate of cetyl. When *iodide of cetyl* (produced by the reaction of iodine, phosphorus, and hydrate of cetyl) is heated with cetylate of soda, at a temperature of 230° Fahr., *oxide of cetyl* is obtained.

Oxide of cetyl ($C_{32}H_{66}O_2$) results, in the manner just indicated, by virtue of the following decomposition:—

The iodide of sodium may be washed out with water, and the oxide of cetyl purified by crystallisation from boiling alcohol or ether. It is a very stable substance; neither hydrochloric nor nitrohydrochloric acid affect it. It melts at about 130° Fahr., and at 572° Fahr. distils without decomposition.

Chloride of cetyl, $C_{32}H_{33}Cl$, is an oily body, lighter than water, derived from hydrate of cetyl by reaction with perchloride of phosphorus. When chloride of cetyl is heated with an alcoholic solution of monosulphide of potassium, *cetyl-sulphydic ether*, is produced, more simply called

Sulphide of cetyl ($C_{64}H_{132}S_2 = C_{32}H_{33}S_2$), purified by washing with water and crystallisation from a mixture of alcohol and ether. It is obtained in spangles of considerable lustre. They melt at 135.5° Fahr., and solidify into a radiate mass of crystals at 129.2° Fahr.

Sulphydrate of cetyl ($C_{32}H_{33}S_2 = C_{32}H_{33}S_2$), or *cetyl-sulphydic acid*, or *cetyl-mercaptan*. When alcoholic solutions of chloride of cetyl and sulphydrate of potash are mixed, sulphydrate and sulphide of cetyl are produced; the first is obtained pure by adding to the mixture acetate of lead, washing the precipitate with water, and finally digesting it in ether, when it dissolves out, and may be crystallised by evaporation. It melts at 123° Fahr., and re-solidifies at about 111° Fahr. In other respects it much resembles sulphide of cetyl.

Cetyl-sulphuric acid ($C_{32}H_{33}O, HO, 2SO_3$), (*sulphocetic acid*). At the temperature of boiling water hydrate of cetyl combines with sulphuric acid; the mass dissolved in alcohol, and an alcoholic solution of potash added, yields sulphate of potash, which precipitates, and *cetylsulphate of potash* ($C_{32}H_{33}O, KO, 2SO_3$), which remains in solution; by evaporation and recrystallisation it is obtained in beautiful pearly plates.

Cetyl-disulphocarbonic acid ($C_{32}H_{33}O, HO, 2CS_2$). The potash salt of this acid, ($C_{32}H_{33}O, KO, 2CS_2$), is obtained by adding finely powdered hydrate of potash to a saturated solution of hydrate of cetyl in bisulphide of carbon. The glue-like product dissolved in alcohol yields on evaporation flocks of *cetyldisulphocarbonate of potash*. The solution of this salt precipitates salts of mercury, silver, lead, and zinc. Hydrochloric acid sets free hydrate of cetyl.

Tri-cetylamine, ($C_{96}H_{198}N$) = $N \left\{ \begin{matrix} C_{32}H_{33} \\ C_{32}H_{33} \\ C_{32}H_{33} \end{matrix} \right.$, obtained by the action of ammoniacal gas on iodide of cetyl at a temperature of about 356° Fahr.; iodide of ammonium precipitates and the liquid portion consists of the above base. From solution in alcohol this substance crystallises in colourless needles. Melting point, 102.2. It combines with acids to form salts, all of which are insoluble in water, but soluble in alcohol or ether.

Cetylaniline (*cetylphenylamine*), ($C_{44}H_{89}N$) = $N \left\{ \begin{matrix} C_{32}H_{33} \\ C_{12}H_5 \end{matrix} \right.$, produced by reacting with excess of aniline on iodide of cetyl. The iodide of phenyl-ammonium that results at the same time is removed by washing with a mixture of ether and water, and the cetylaniline converted into a hydrochlorate, which is decomposed with caustic potash and crystallised from boiling alcohol. Thus obtained, it occurs in plates of considerable lustre. Melting point, 107.6° Fahr.; solidifying point, 82.4° Fahr. It is insoluble in water, very soluble in alcohol or ether; it neither precipitates metallic solutions nor acts upon vegetable colours. It combines with acids to form salts, most of which are crystalline.

Dicetylaniline, $C_{76}H_{71}N = N \left\{ \begin{matrix} C_{32}H_{33} \\ C_{32}H_{33} \\ C_{12}H_5 \end{matrix} \right.$, is obtained by acting with one equivalent of iodide of cetyl on one equivalent of cetylaniline. It much resembles the latter body, but is more fusible.

CETYLDISULPHOCARBONIC ACID. [CETYL.]

CETYLIC ACID. [PALMITIC ACID.]

CEVADIC ACID, a peculiar acid obtained by Pelletier and Caventou from cevadilla, the seed of the *Veratrum sabadilla*. When this seed is digested in ether, a fat oil, consisting of stearine and elaine, is dissolved; the oil, separated from the ether by distillation, is then saponified by potash; this soap is decomposed by tartaric acid; the fat acids, set free, are separated by the filter; and the solution being distilled, cevadic acid, mixed with much water, is condensed in the

receiver: this is saturated with baryta, and the salt obtained by evaporation to dryness is mixed with phosphoric acid and distilled. The cevadic acid sublimes in white pearly needles which fuse at 67° Fahr., and exhale the same smell as butyric acid, or as rancid butter, which owes its smell to the latter acid. Cevadic acid sublimes at a few degrees above its melting point, and it is soluble in water, alcohol, and ether. Its salts are but little known, but they retain the smell of the acid; the salt of ammonia precipitates the persalts of iron white. Cevadic acid is also probably contained in the root of white hellebore and of colchicum. Its composition is not known.

CHÆROPHYLLINE. An alkaloid of unknown composition, found in the grains of the *Chaerophyllum bulbosum*.

CHAIN-CABLES. [GROUND TACKLE.]

CHAIN (in surveying) is a measuring chain of 100 links, altogether 4 poles, or 66 feet, or 22 yards in length, so that ten square chains make an acre. It is commonly called Gunter's chain, having been first used by him, and described in his treatise on the cross-staff, &c., in the following words: "We may measure the length and breadth by chains, each chain being four perches in length, and divided into a hundred links, then will the work be more easie in arithmetic. For as ten to the breadth in chains: so the length in chains to the content in acres."

The chain is of universal use in modern surveying; but care must be taken to verify its length from time to time, since the material is very extensible, and the apparatus must necessarily be roughly used. It is stated in the account of Troughton (Ast. Soc. Monthly Notice, Feb. 1836), that the chains of two surveyors, who differed in their measurement, being sent to him, one was found two inches too short, the other three inches too long.

CHAIN RULE. This is a name given to a rule of arithmetic by which when a succession of equivalents is given, the last of each being of the same kind as the first of the next, a relation of equivalence is established between numbers of the first and last kind mentioned. Thus, if three horses be worth seven cows, and ten cows be worth thirty-nine sheep, and two sheep be worth fifty-three geese, it can be found how many geese are worth, say eleven horses, or how many horses are worth a thousand geese. Such questions, and the mode still adopted of solving them, are found in the Hindu 'Lilivati,' and in the earliest European books on arithmetic and algebra. They involve a *chain* of equivalents, each link of which is joined to the preceding and following one by the same names, and the first name of the first link is the same as the second name of the last; whence the name *chain-rule*. The process applies with great practical use to questions in the arbitration of exchanges.

The process is nothing but that of composition of ratios; but it may be simply exhibited thus:—Let it be that

3 horses	are worth	7 cows,
10 cows	"	39 sheep,
2 sheep	"	53 geese,
How many geese	"	11 horses?

From the first, 3×10 horses are worth 7×10 cows, which from the second, are worth $7 + 39$ sheep: hence $2 \times 3 \times 10$ horses are worth $2 \times 7 \times 39$ sheep or $53 \times 7 \times 39$ geese. Hence $2 \times 3 \times 10 \times 11$ horses are worth $53 \times 7 \times 39 \times 11$ geese, or 11 horses are worth $53 \times 7 \times 39 \times 11 \div 2 \times 3 \times 10$ geese. By such reasoning the following rule is established:—divide the product of the numbers in the column which has not vacancy by the product of the numbers in the column which has a vacancy for the unknown quantity, and the quotient is the number with which the vacancy is to be filled up.

It is obvious that any multiplier which exists in both columns may be struck out before commencing the process: this is the peculiar advantage of the rule, namely, that it points out at once all the simplifications which can be introduced by division.

The common rule of three, and various other rules, may be brought under the chain-rule; but an attempt is sometimes made to reduce under it every question the answer to which is found by dividing one product by another. This has been done in all times, from that of the Lilivati to the present. For example, if seven men can reap three acres in ten days, how long will it take thirteen men to reap nineteen acres? The answer is found no doubt by dividing $7 \times 19 \times 10$ by 13×3 ; but if we attempt to put these down in the chain form we have—

10 days	3 acres
19 acres	13 men
7 men	? days.

Now even if we grant that ten days are, in the first clause, an equivalent for (being the time of reaping) three acres, and that nineteen acres are in the second clause an equivalent for (or the work of) thirteen men: we still find it impossible to make out in what sense the seven men of the first clause are an equivalent to the unknown number of days in the second. But in truth the ten days in the first clause are not absolutely and independently the time of doing the three acres, but only on condition that seven men are employed; while in the second clause the thirteen men are only the reapers of nineteen acres on the supposition of some one definite but unknown time being allowed. The question is not therefore of the same class as that which was first proposed, in which each quantity mentioned

was absolutely and unconditionally an equivalent in value to one of the others.

CHAIN SHOT. Two iron balls linked together by a chain eight or ten inches long are so called. They were formerly used on board ship.

CHALCIDICUM, an apartment separated by a partition from the body of a basilica or other large building. The name, Festus says, is derived from the city Chalcis. Vitruvius (v. i.) directs that chalcidica should be constructed at the ends of a basilica, if the area is disproportionately long. [**BASILICA.**] A building has been discovered in Pompeii which appears to be a chalcidicum from the inscription:—

Eumachia. L. F. Sacerd. Public. Nomine. Suo. Et.
M. Numistri. Frontonis. Fili. Chalcidicum.

Cryptam. Porticum. Concordiae. Augustae.
Pietati. Sua. Pecunia. Fecit. Eademque.
Dedicavit.

The chalcidicum is, in this instance, considered to be an inclosed space or vestibule at the end of the open area of the building, in the centre of which space a large semicircular recess has been formed. The entire structure, at Pompeii, consists of a large area, about 130 feet by 65, surrounded by a double gallery, and has in front a pseudo-dipteral portico of eighteen columns elevated on pedestals. Under the centre of the portico was the great public entrance, was closed with folding doors, turning in sockets of bronze, and secured by bolts. On each side of the entrance there are two large circular recesses, and beyond these again are raised platforms, the staircases to which still remain. By a reference to the annexed plan, the large area of this building will be seen, with the solid desks or places for exhibiting goods, possibly cloth, for sale. The area was surrounded with a beautiful marble colonnade. Under the colonnade, at the end opposite the entrance, is the large recess (A), with offices (B) adjoining, which is considered to be the chalcidicum, and possibly was

[Plan of the Chalcidicum at Pompeii.]

a commercial tribunal, or perhaps a place for ratifying mercantile contracts, &c. Behind the colonnade is a gallery called crypto-porticus (C), either for winter use or a depositary for goods. At the back of the chalcidicum there is a passage entrance (D) leading into the crypto-porticus; and near this entrance into the crypto-porticus is a statue (E) of a certain Eumachia, erected by the *fullones* (cloth-sourers) of Pompeii to her memory. It is not improbable that there was a double gallery over the colonnade and crypto-porticus, from the circumstance of a staircase at E.

The term chalcidicum appears sometimes to have been applied to a sort of large porch attached to the entrance of a building; sometimes to a chamber or chambers by the tribune reserved for the use of the judges; but the specific use of the term is by no means certain. The word occurs on the Monumentum Ancyranum, in connection with Curia and Templum.

CHALDRON, an old measure, containing thirty-six heaped bushels. The word appears to come from *caldarium*; in French *chaudron*, or *chaudrière*. Richelet observes that brewers, sugar-refiners, dyers, &c., make use of the *chaudrière*. Its proper signification, of a large metal vessel, or boiler, was probably transferred among us to denote a large measure of capacity. It was chiefly used in the sale of coals which by an act 5 & 6 Wm. IV. c. 63, are now sold by weight.

CHALK (in Geology), a rock which forms the higher part of a series or group termed cretaceous.

Chalk is composed of nearly 44 parts of carbonic acid and 56 of lime. It is extensively used in agriculture to improve various soils. The best land for the growth of wheat contains a certain portion of argillaceous, siliceous, and calcareous earth; and when this last is deficient, the addition of chalk improves the soil more than any quantity of animal or vegetable manure could do alone. Lime produces a greater effect by its caustic nature; but as it is always put on the land in much smaller quantities than chalk, it does not so permanently improve it. Good chalk should be firm and compact, should break readily, and crumble into a fine powder; it should readily absorb moisture, and when the lumps are exposed to frost after having been wet, they should break into minute square fragments. Chalk is called a manure, and it is so, in as far as everything which increases the crop may be so called; but it is a great mistake to suppose that it may be substituted for animal and vegetable manures. Chalk may so far supersede dung that where it is used a portion of the latter may be dispensed with;
